# The Crystal Structure and Molecular Configuration of an <br> Asymmetric 1,2-Dimethyl-1,2-dicarbollide Complex of Nickel, Racemic ( $3,4^{\prime}$ ) $-\left[\left(\mathrm{CH}_{8}\right)_{2} \mathrm{~B}_{8} \mathrm{C}_{2} \mathrm{H}_{8}\right]_{2} \mathrm{Ni}^{\text {iV } 1}$ 

Melvyn R. Churchill ${ }^{2}$ and Karen Gold ${ }^{3}$<br>Contribution from the Mallinckrodt Laboratory, Department of Chemistry, Harvard University, Cambridge, Massachusetts 02138. Received June 5, 1969

#### Abstract

CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{1 \mathrm{~V}}\) has previously been shown to exist in two modifications, one of which (isomer B) shows four types of methyl protons in its magnetic resonance spectrum and may be resolved into enantiomers via the corresponding $\left\{\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}{ }^{111}\right\}$ - anion. An X-ray structural study of racemic isomer B shows it to be 3,4'-commo-[1,2-dimethyl-1,2-dicarba-3-nickela-closo-dodecaborane]-[1', $2^{\prime}$-dimethyl-1', $2^{\prime}$ 'dicarba-4'-nickela-closododecaborane]. The complex crystallizes in the centrosymmetric monoclinic space group $P 2_{1 / n}\left(\mathrm{C}_{2 \mathrm{~h}}{ }^{5}\right.$; no. 14) with $a=13.489 \pm 0.010, b=20.223 \pm 0.012, c=7.626 \pm 0.006 \AA, \beta=93.62 \pm 0.05^{\circ}, V=2076 \AA^{3}, Z=4$. Observed and calculated densities are $1.23 \pm 0.05$ and $1.215 \mathrm{~g} \mathrm{~cm}^{-3}$, respectively. The use of three-dimensional counter data to $\sin \theta=0.75$ ( $\mathrm{Cu} \mathrm{K} \alpha$ radiation) has led to the location of all nonhydrogen atoms, the final discrepancy index being $R_{F}=8.64 \%$ for the 1396 independent nonzero reflections. The discrete molecular units of $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{1 \mathrm{~V}}$ are separated by normal van der Waals distances. The $\mathrm{Ni}^{1 \mathrm{v}}$ ion is "sandwiched" between two mutually staggered 1,2 -dimethyl-1,2-dicarbollide ligands and is the common ( $3,4^{\prime}$ ) apex of the two icosahedra. Thus, in one dicarbollide ligand, both $\mathrm{C}(1)$ and $\mathrm{C}(2)$ are in the basal pentagonal bonding face, whereas in the other ligand only $\mathrm{C}\left(1^{\prime}\right)$ is directly bonded to the nickel, with $\mathrm{C}\left(2^{\prime}\right)$ being in the upper pentagonal plane of this icosahedron. There is an angle of $14^{\circ} 51^{\prime}$ between the bonding faces of the two dicarbollide ligands.

$\mathrm{A}^{\mathrm{n}}$unusual series of $\mathrm{Ni}(\mathrm{III})$ and $\mathrm{Ni}(\mathrm{IV})$ complexes of the 1,2-dimethyl-1,2-dicarbollide [ $\mathrm{D}^{2-}$ ] ligand has recently been prepared. ${ }^{4}$ Chemical studies ${ }^{4}$ show the following sequence of isomerization and redox reactions (Scheme I). There are three discrete $\mathrm{Ni}(\mathrm{III})$ de-

Scheme I

rivatives and two $\mathrm{Ni}(\mathrm{IV})$ derivatives. The series B [ $\left.\mathrm{D}_{2} \mathrm{Ni}^{\mathrm{III}}\right]$ - ion has been resolved into enantiomers and oxidized to optically active series $\mathrm{B}\left[\mathrm{D}_{2} \mathrm{Ni}^{1 \mathrm{~V}}\right]$. The series $\mathrm{B}\left[\mathrm{D}_{2} \mathrm{Ni}^{\mathrm{IV}}{ }^{\mathrm{V}}\right.$ ] exhibits four types of methyl protons in its proton magnetic resonance spectrum, whereas series $\mathrm{C}\left[\mathrm{D}_{2} \mathrm{Ni}^{\mathrm{IV}}\right]$ shows only two kinds of methyl protons. The present structural study was undertaken in order to provide an unambiguous explanation for the optical activity and the four different methyl environments in series $\mathrm{B}\left[\mathrm{D}_{2} \mathrm{Ni}^{1 \mathrm{~V}}\right]$.

Structural studies of related complexes in this series have been performed by other workers. ${ }^{5,6}$

[^0]
## Unit Cell and Space Group

Crystals of racemic series B $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{3}\right] \mathrm{Ni}^{\text {IV }}$ were supplied by Professor M. F. Hawthorne of the University of California, Riverside. Optical examination and a reciprocal lattice symmetry of $\mathrm{C}_{2 \mathrm{~h}}(2 / \mathrm{m})$ indicated that the crystals belonged to the monoclinic system. A survey of $0-2 k l, h k 0-2$ Weissenberg photographs and $h 0-1 l, 0-1 k l$ precession photographs (all taken with Cu $\mathrm{K} \alpha$ radiation) revealed the systematic absences $h 0 l$ for $h+l=2 n+1$ and $0 k 0$ for $k=2 n+1$, consistent with the centrosymmetric space group $\mathrm{P}_{1} / \mathrm{n}\left(\mathrm{C}_{2 \mathrm{~h}}{ }^{5}\right.$; no. 14) .

Unit cell parameters, calculated from calibrated $\left(a_{\mathrm{NaCl}}=5.640 \AA\right)$ zero level precession photographs ( $\mathrm{Cu} \mathrm{K} \alpha$ radiation; $\bar{\lambda} 1.5418 \AA$ ) at $23 \pm 2^{\circ}$ are: $a$ $=13.489 \pm 0.010, b=20.223 \pm 0.012, c=7.626 \pm$ $0.006 \AA, \beta=93.62 \pm 0.05^{\circ}$. (Errors given are the "maximum possible errors" based on the sum of the inaccuracies involved in measuring (on precession photographs) the positions of diffraction rows from the crystal under investigation, and from our standard NaCl crystal.) The unit cell volume is $2076 \AA^{3}$. The observed density of $1.23 \pm 0.05 \mathrm{~g} \mathrm{~cm}^{-3}$ (by flotation in aqueous zinc iodide solution) agrees with that calculated for $M=379.81$ and $Z=4\left(\rho_{\text {calcd }}=1.215 \mathrm{~g} \mathrm{~cm}^{-3}\right)$.

## Collection and Reduction of X-Ray Diffraction Data

The complex crystallizes as bright orange platelets with well-developed ( 010 ) faces. Most of the supplied crystals appeared to be twinned and, of a total of some $40-50$ examined by diffraction methods, only two were found to be suitable for a structural analysis. The crystals are air-stable and are not X-ray sensitive. Two crystals were used during the analysis. Crystal I ( 0.12 $\times 0.06 \times 0.23 \mathrm{~mm}$ ) was aligned along the $c$ axis, and crystal II ( $0.14 \times 0.09 \times 0.26 \mathrm{~mm}$ ) was aligned along the $a$ axis. (Dimensions refer sequentially to $\vec{a}, \vec{b}, \vec{c}$.)

Intensity data were collected with a $0.01^{\circ}$-incrementing Buerger automated diffractometer, using a "stationary background, $\omega$-scan, stationary background" counting sequence. The apparatus and the experimental technique have been described previously. ${ }^{7}$ Details specific to the present analysis include: (i) $\mathrm{Cu} \mathrm{K} \alpha$ radiation ( $\bar{\lambda} 1.5418 \AA$ ) was used. (ii) The scan angle was chosen as $\omega(h k l)=[3.00+1.0 / \mathrm{L}(h k l)]^{\circ}$, where $1 / L(h k l)$ is the Lorentz factor for the reflection $h k l .^{8}$ The count associated with this scan is $C(h k l)$. (iii) Initial and final backgrounds, $B_{1}(h k l)$ and $B_{2}(h k l)$, were each counted for one-fourth the time of the main scan. (iv) The overall stability of the system was monitored by remeasuring a carefully preselected check reflection after every 20 reflections. The maximum deviation from the mean was $\sim 2.5 \%$. (v) $I(h k l)$, the net intensity of the reflection $h k l$, was calculated as

$$
I(h k l)=C(h k l)-2\left[B_{1}(h k l)+B_{2}(h k l)\right]
$$

Reflections were weighted according to the scheme

$$
\begin{gathered}
I(h k l)>4900, \sigma\{I(h k l)\}=0.1[I(h k l)] \\
I(h k l) \leqslant 4900, \sigma\{I(h k l)\}=7.0[I(h k l)]^{1 / 2}
\end{gathered}
$$

Data were subsequently rejected on two bases: (i) $B_{1}(h k l) / B_{2}(h k l)$ or $B_{2}(h k l) / B_{1}(h k l) \geqslant 4.0$, symptomatic of overlap of adjacent reflections. (ii) $I(h k l) \leqslant 3[C(h k l)$ $\left.+B_{1}(h k l)+B_{2}(h k l)\right]^{1 / 2}$, indicating that the reflection was not significantly different from zero.
With crystal I mounted along the $c$ axis, equiinclination geometry was used in collecting a total of 2275 reflections in the zones $h k 0-6$. A total of 2144 reflections from the zones $0-11 \mathrm{kl}$ were collected from crystal II. This represents data complete to $\sin \theta=0.75$ and includes all data visible on long-exposure Weissenberg films All data were corrected for Lorentz and polarization effects, and absorption corrections were applied. ${ }^{9}$ Transmission factors varied from 0.88 to 0.94 for data from crystal I (volume $=0.0012 \mathrm{~mm}^{3}$ ) and from 0.77 to 0.90 for data from crystal II (volume $=$ $0.0033 \mathrm{~mm}^{3}$ ). All data were placed on a common scale via a least-squares procedure which minimizes a sum of residuals linear in the logarithms of the individual scale factors. ${ }^{10}$ The resulting 1396 independent nonzero reflections were placed on an absolute scale by means of a Wilson plot, ${ }^{11}$ which also yielded the overall isotropic thermal parameter $\bar{B}=3.14 \AA^{2}$.

All subsequent calculations were preformed using the CRYRM system. ${ }^{12}$

## Solution and Refinement of the Structure

Throughout the analysis scattering factors for neutral carbon, boron, and hydrogen were used; ${ }^{13 a}$ the Thomas-

Figure 1. The $\left(3,4^{\prime}\right)-\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{1 \mathrm{~V}}$ molecule, projected on (100). The $68 \%$ probability envelopes of the thermal vibration ellipsoids are shown. (The diagram was constructed using otlips, an IBM 1620/CALCOMP program by Dr. P. H. Bird.)

Fermi-Dirac values for neutral nickel ${ }^{13 b}$ were corrected for the real, but not for the imaginary, component of dispersion $\left(\Delta f^{\prime}(\mathrm{Ni})=-3.1 \mathrm{e}, \Delta f^{\prime \prime}(\mathrm{Ni})=+0.6 \mathrm{e}\right) .{ }^{13 \mathrm{c}}$ The residual minimized during least-squares refinement processes was $\Sigma w\left(\left|F_{\mathrm{o}}\right|^{2}-\left|F_{\mathrm{c}}\right|^{2}\right)^{2}$, where $w(h k l)=$ $\left[\sigma\left\{F^{2}(h k l)\right\}\right]^{-2}$. Discrepancy indices are defined thus

$$
\begin{gathered}
R_{F}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}} \| / \Sigma\right| F_{\mathrm{o}}\right| \\
R_{w F^{2}}=\Sigma_{w v}\left(\left|F_{\mathrm{o}}\right|^{2}-\left|F_{\mathrm{c}}\right|^{2}\right)^{2} / \Sigma_{w}\left|F_{0}\right|^{4}
\end{gathered}
$$

The position of the nickel atom ( $x=0.683, y=$ $0.263, z=0.488$ ) was determined from a three-dimensional Patterson synthesis. A three-dimensional Fourier synthesis phased only by the nickel atom ( $R_{F}=44.3 \%$ ) yielded unambiguously the positions of all nonhydrogen atoms. One cycle of least-squares refinement of positional and individual isotropic thermal parameters led to a reduction in the discrepancy indices to $R_{F}=22.11 \%$ and $R_{w F^{2}}=33.85 \%$. Three cycles of full-matrix leastsquares refinement of all positional parameters, isotropic thermal parameters for boron and carbon atoms, and anisotropic thermal parameters for the nickel atom led to convergence at $R_{F}=13.00 \%, R_{w F^{2}}=2.75 \%$. A three-dimensional difference Fourier synthesis now showed clear evidence for anisotropic motion for boron and carbon atoms, and also led to the location of all hydrogen atoms other than those of the methyl groups. (Peak heights, in e $\AA^{-3}$, were: $\mathrm{H}(4), 0.55 ; \mathrm{H}(5), 0.44$; $\mathrm{H}(6), 0.44 ; \mathrm{H}(7), 0.30 ; \mathrm{H}(8), 0.44 ; \mathrm{H}(9), 0.38 ; \mathrm{H}(10)$, $0.35 ; \mathrm{H}(11), 0.34 ; \mathrm{H}(12), 0.36 ; \mathrm{H}\left(3^{\prime}\right), 0.42 ; \mathrm{H}\left(5^{\prime}\right)$, $0.42 ; \mathrm{H}\left(6^{\prime}\right), 0.45 ; \mathrm{H}\left(7^{\prime}\right), 0.55 ; \mathrm{H}\left(8^{\prime}\right), 0.46 ; \mathrm{H}\left(9^{\prime}\right)$, $0.37 ; \mathrm{H}\left(10^{\prime}\right), 0.26 ; \mathrm{H}\left(11^{\prime}\right), 0.43 ; H\left(12^{\prime}\right), 0.34$. These may be compared with carbon atom peak heights of $\sim 3.5$ e $\AA^{-3}$ on an "observed" Fourier synthesis at this stage.) Refinement was continued using anisotropic thermal parameters for all nonhydrogen atoms. Hydrogen atoms (other than those of the methyl groups) were included in calculated positions with $d(\mathrm{~B}-\mathrm{H})=$ $1.00 \AA$ and the appropriate icosahedral geometry. ${ }^{14}$

[^1]
${ }^{a}$ The table shows $h, k, 10\left|F_{0}\right|, 10\left|F_{0}\right|$ in blocks of constant $l$.

Each was assigned an isotropic thermal parameter of $1.4 \AA^{2}$. Neither the positions nor the thermal parameters of the hydrogen atoms were allowed to refine. Hydrogen atom positions were, however, redefined with respect to the new boron positions after each cycle of refinement. Seven cycles of "two-matrix" ${ }^{15}$ refinement of positional and anisotropic thermal parameters for the 27 nonhydrogen atoms led to convergence at $R_{F}=$ $8.64 \%$ and $R_{F w^{2}}=2.12 \%$; in the last cycle, no parameter varied by more than one-tenth of its standard deviation and refinement was judged to be complete. A final difference Fourier synthesis showed no unexpected features (nor any methyl hydrogens), thus validating the results of the least-squares refinement procedure, and confirming the correctness of the molecular structure.

[^2]The final standard deviation of an observation of unit weight was 1.35 .

Table I shows the final observed and calculated structure factors. Atomic coordinates are collected in Table II. Anisotropic thermal parameters are listed in Table III; their associated atomic vibration ellipsoids are defined in Table IV and illustrated in Figure 1.

## The Molecular Structure

Intramolecular distances and their estimated standard deviations (esd's) are shown in Table V(a). Average bond distances, with their root-mean-square deviations from the mean, are collected in Table $V(b)$. Average bond angles are given in Table VI. (Since the linked icosahedral $\left(\mathrm{B}_{9} \mathrm{C}_{2}\right)_{2} \mathrm{Ni}$ skeleton of the molecule defines 240 bond angles, and the methyl carbon atoms give rise to 20 more angles (neglecting all hydrogen atoms) it was thought inappropriate to report individual bond angles.) Figure 1 shows the molecule projected

Table II. Final Atomic Positions ${ }^{a}$ for $\left(3,4^{\prime}\right)-\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{1 v}$

${ }^{a}$ Estimated standard deviations, shown in parentheses, are rightadjusted to the least significant digit of the preceding number.
on (100) and illustrates the scheme used for numbering all nonhydrogen atoms. The hydrogen atoms of the icosahedra, which have been omitted from the diagram for the sake of clarity, are numbered similarly to their attached boron atoms.

The $d^{6} \mathrm{Ni}(\mathrm{IV})$ ion is "sandwiched" between two mutually staggered carborane moieties and achieves the 18 outer electron ('noble gas') configuration, compatible with the observed diamagnetism of the complex, by the donation of six electrons from each of the substituted dicarbollide ligands.

In each dicarbollide ligand the two carbon atoms of the icosahedral framework remain adjacent to each other and retain their bonded methyl groups, as in the parent [ $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}{ }^{2-}$ ] dianion. However, the ligands have different configurations. The lower ligand (unprimed in Figure 1) has its two icosahedral carbon atoms in the bonding pentagonal face: this ligand may thus be described as a (3)-1,2-dimethyl-1,2-dicarbollide dianion. The upper ligand (primed in Figure 1) has only one carbon atom in the basal pentagonal face; the second icosahedral carbon of this ligand does not
bond directly to the nickel ion. This ligand is thus a (4)-1,2-dimethyl-1,2-dicarbollide dianion. The molecule thus may be systematically named as $3,4^{\prime}$-commo-[1,2-dimethyl-1,2-dicarba-3-nickela - closo-dodecabo-rane]-[1', $2^{\prime}$-dimethyl- $1^{\prime}, 2^{\prime}$-dicarba-4'-nickela-closo-dodecaborane]. ${ }^{16}$

It should be emphasized that the present ( $3,4^{\prime}$ )$\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{NiI}^{\text {IV }}$ molecule is the first reported example of a transition metal complex in which a dicarbollide ligand fails to have both carbon atoms in the basal (bonding) pentagonal face. In all transition metal dicarbollide complexes for which structural studies have previously been published ( viz., ( $\mathrm{C}_{\bar{j}} \mathrm{H}_{\bar{j}}$ ) Fe $\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right),{ }^{17} \quad \mathrm{Cs}^{+}\left[\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right) \mathrm{Re}(\mathrm{CO})_{3}{ }^{-}\right],{ }^{18} \quad\left[\mathrm{Et}_{4} \mathrm{~N}^{+}\right]_{2}[\mathrm{Cu}-$ $\left.\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}{ }^{2-}\right],{ }^{19} \quad \mathrm{Cs}+\left[\mathrm{Co}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}{ }^{-}\right],{ }^{20} \quad\left[\mathrm{PPh}_{3} \mathrm{Me}^{+}\right][\mathrm{Cu}-$ $\left.\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}{ }^{-}\right],{ }^{21}\left[\mathrm{Me}_{4} \mathrm{~N}^{+}\right]\left[\mathrm{Co}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{8} \mathrm{Br}_{3}\right)_{2}{ }^{-}\right],{ }^{22}$ and $\left(\mathrm{B}_{9} \mathrm{C}_{2}{ }^{-}\right.$ $\left.\mathrm{H}_{10}\right)_{2} \mathrm{CoS}_{2} \mathrm{CH}^{23}$ ), the carborane moiety is present as a (3)-1,2-dicarbollide ligand. The present (3,4')-[( $\left.\mathrm{CH}_{3}\right)_{2}{ }^{-}$ $\left.\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{I V}$ molecule also represents the first reported example of a bis(dicarbollide) complex in which the two dicarbollide ligands are found to bond differently to the central metal ion. Thus, the $\left[\mathrm{Co}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{8} \mathrm{Br}_{3}\right)_{2}{ }^{-}\right.$] ion has an inversion center at the metal atom, ${ }^{22}$ the [ $\left.\mathrm{Co}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}{ }^{-}\right]$ion is disordered such that the relative orientation of the ligands cannot properly be determined, ${ }^{20}$ the $\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{10}\right)_{2} \mathrm{CoS}_{2} \mathrm{CH}$ molecule has $\mathrm{C}_{2}$ symmetry with the pairs of dicarbollide carbons lying in close proximity, ${ }^{23}$ and the $\left[\mathrm{Cu}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}{ }^{-}\right]^{21}$ and $[\mathrm{Cu}-$ $\left.\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}{ }^{2-}\right]^{19}$ ions retain $\mathrm{C}_{2 \mathrm{~h}}$ symmetry even though their dicarbollide cages are "slipped" relative to each other; and these compounds may be regarded formally as pseudo- $\pi$-allyl complexes with only the $\mathrm{B}_{3}$ fragment of the basal $B_{3} C_{2}$ moiety bonding to the central copper ions.

In the $\left(3,4^{\prime}\right)-\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{\text {IV }}$ molecule the bonding pentagonal faces of the carborane ligands (hereafter called $\alpha$ and $\alpha^{\prime}$ ) therefore contain the atoms $\mathrm{C}(1)-\mathrm{C}(2)-$ $\mathrm{B}(7)-\mathrm{B}(8)-\mathrm{B}(4)$ and $\mathrm{C}\left(1^{\prime}\right)-\mathrm{B}\left(3^{\prime}\right)-\mathrm{B}\left(8^{\prime}\right)-\mathrm{B}\left(9^{\prime}\right)-\mathrm{B}\left(5^{\prime}\right)$, respectively. The $\beta$ and $\beta^{\prime}$ pentagons, which lie directly above and in a staggered conformation with respect to $\alpha$ and $\alpha^{\prime}$, are defined by $\mathrm{B}(5)-\mathrm{B}(6)-\mathrm{B}(11)-\mathrm{B}(12)-\mathrm{B}(9)$ and $\mathrm{C}\left(2^{\prime}\right)-\mathrm{B}\left(7^{\prime}\right)-\mathrm{B}\left(12^{\prime}\right)-\mathrm{B}\left(10^{\prime}\right)-\mathrm{B}\left(6^{\prime}\right)$, respectively. As shown in Table VII, the five atoms of the $\alpha$ pentagon have a root-mean-square (rms) deviation of $0.035 \AA$ from the least-squares plane ${ }^{24} 0.1599 X+0.9733 Y+0.1641 Z$ $=5.7466$, and the atoms of the $\beta$ pentagon have an rms deviation of $0.020 \AA$ from the least-squares plane ${ }^{24}$ $0.1538 X+0.9760 Y+0.1537 Z=4.2000$. The dihedral angle between the $\alpha$ and $\beta$ planes is $1^{\circ} 24^{\prime}$ (i.e., not significantly different from zero). In the other ligand, the $\alpha^{\prime}$ pentagon has an rms deviation of $0.012 \AA$ from the plane ${ }^{24}-0.0995 X+0.9866 Y+0.1291 Z=6.4089$, and the $\beta^{\prime}$ pentagon has an rms deviation of $0.030 \AA$ from the plane ${ }^{24}-0.1201 X+0.9871 Y+0.1239 Z=7.8311$.

${ }^{a}$ Direction cosines (dc's) are referred to the monoclinic axes. They have been multiplied by $10^{3}$. ${ }^{b}$ The major, median, and minor axes of the atomic vibration ellipsoids are defined in terms of $B$ (the normal isotropic thermal parameter, having units of $\AA^{2}$ ). The transformation to root-mean-square displacement, $\left(\bar{U}^{2}\right)^{1 / 2}$, is: $\left(\bar{U}^{2}\right)^{1 / 2}=\left[B / 8 \pi^{2}\right]^{1 / 2} . \quad{ }^{6}$ The $68 \%$ probability contours of the vibration ellipsoids are illustrated in Figure 1.

The dihedral angle between the $\alpha^{\prime}$ and $\beta^{\prime}$ planes is $0^{\circ} 00^{\prime}$. In none of these four systems does any atom deviate from its least-squares plane by more than $3 \sigma$, so each of the latitudinal pentagons is planar within experimental error.

There is a dihedral angle of $14^{\circ} 51^{\prime}$ between the $\alpha$ and $\alpha^{\prime}$ pentagonal planes, showing that the two 1,2 -di-methyl-1,2-dicarbollide ligands are distinctly nonparallel. This is in contrast to other reported metallobis(carbollide) structures, in which the two dicarbollide

${ }^{a}$ Estimated standard deviations, shown in parentheses, are rightadjusted to the least significant digit of the previous number.
ligands are essentially parallel. However, there is a small dihedral angle ( $\sim 3^{\circ}$ ) between the dicarboll de ligands in the $\left[\mathrm{Co}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{8} \mathrm{Br}_{3}\right)_{2}{ }^{2}\right]$ ion, believed ${ }^{22}$ to be due to interligand bromine $\cdots$ hydrogen repulsions. The dihedral angle of $14^{\circ} 51^{\prime}$ in the present complex is also probably the result of steric, rather than electronic, effects. Pauling ${ }^{25}$ estimates the van der Waals radius of a methyl group as $2.0 \AA$. The $\mathrm{Me}(1) \cdots \mathrm{Me}\left(1^{\prime}\right)$ distance of $3.414 \pm 0.017 \AA$ in $\left(3,4^{\prime}\right)-\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{\mathrm{VV}}$ is thus ca. $0.6 \AA$ below the sum of the covalent radii, and presumably is the cause of the large separation of $\mathrm{C}(1)$ and $\mathrm{C}\left(1^{\prime}\right)(3.559 \pm 0.013 \AA)$ as compared to the

${ }^{a}$ Esd's for the individual lowest and highest values for a given type of bond angle are those obtained from the least-squares refinement. ${ }^{b}$ Esd's for the average bond angles were calculated from the equation given in footnote $b$ of Table V(b).
relatively short $\mathrm{B}(7) \cdots \mathrm{B}\left(9^{\prime}\right)$ distance of $2.855 \pm 0.018$ $\AA$ directly opposite to this. (For other interannular contacts, see Table Va.)
It should be noted, however, that the observation of four distinct methyl resonances in the proton magnetic resonance spectrum ${ }^{4}$ is the result of the four different chemical environments of methyl groups. There is no interlocking of methyl groups, as may easily be recognized by observing that $\mathrm{C}\left(1^{\prime}\right)$, although as close as possible to $\mathrm{C}(1)$, is well removed from the vicinity of $\mathrm{C}(2)$.
The nickel ion lies $1.540 \AA$ above the $\alpha$ plane and $1.518 \AA$ below the $\alpha^{\prime}$ plane. Distances from the nickel to atoms of the $\alpha^{\prime}$ plane are essentially equal, the short-

Dihedral angles: $\alpha / \alpha^{\prime}=14^{\circ} 51^{\prime}, \alpha / \beta=1^{\circ} 24^{\prime}, \alpha^{\prime} / \beta^{\prime}=0^{\circ} 00^{\prime}$
${ }^{a}$ See footnote $a$, Table II. ${ }^{b}$ Planes are defined as $c_{1} X+c_{2} Y$ $+c_{3} Z=d$, where $X, Y, Z$ are Cartesian coordinates which are related to the monoclinic cell coordinates $(x, y, z)$ by the transformations: $X=x a+z c \cos \beta, Y=y b$, and $Z=z c \sin \beta$.
est being $\mathrm{Ni}-\mathrm{B}\left(9^{\prime}\right)=2.107 \pm 0.012 \AA$, and the longest being $\mathrm{Ni}-\mathrm{C}\left(1^{\prime}\right)=2.163 \pm 0.009 \AA$. Distances from the nickel to atoms of the $\alpha$ plane vary quite significantly: the nickel-carbon distances of $2.225 \pm 0.009$ $\AA$ and $2.195 \pm 0.009 \AA$ are significantly longer than the nickel-boron distances ( $2.092 \pm 0.013 \AA, 2.050 \pm 0.013$ $\AA$, and $2.104 \pm 0.013 \AA$ ). It appears, therefore, that the dihedral angle of $14^{\circ} 51^{\prime}$ between $\alpha$ and $\alpha^{\prime}$ planes results primarily in asymmetric bonding of the nickel to the (3)-1,2-dimethyl-1,2-dicarbollide ligand. (Another measure of the tilting of the $\alpha$ plane relative to the $\alpha^{\prime}$ plane is the $\mathrm{B}(10)-\mathrm{Ni}-\mathrm{B}\left(11^{\prime}\right)$ angle of $168.3 \pm 0.3^{\circ}$.)

Average values for the various types of bond lengths and angles within the molecule are compiled in Table V(b) and Table VI, respectively. Root-mean-square deviations from the mean value have been calculated (see Table V(b), footnote b). Since the two ligands are nonidentical in position of coordination to the nickel ion, and in relative orientations within the molecule (i.e., one ligand is symmetrically bonded while the other is not, vide supra), the large values of some overall rms deviations (e.g., for nickel-boron bond lengths) probably reflect simply a chemical nonequivalence of averaged parameters.

The average B-B, B-C, and C-C distances of 1.742 $\pm 0.036 \AA, 1.704 \pm 0.030 \AA$, and $1.677 \pm 0.057 \AA$, respectively, are in good agreement with values found in other icosahedral carborane derivatives, i.e., in $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)$ $\mathrm{Fe}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right),{ }^{17} \quad\left[\left(\mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right) \mathrm{Re}(\mathrm{CO})_{3}-\right]^{18} \quad\left[\mathrm{Cu}\left(\mathrm{B}_{9} \mathrm{C}_{2}-\right.\right.$ $\left.\left.\mathrm{H}_{11}\right)_{2}{ }^{2-}\right],{ }^{19}\left[\mathrm{Co}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}-1,{ }^{20} \quad\left[\mathrm{Cu}\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right)_{2}-{ }^{-1},{ }^{21} \quad[\mathrm{Co}-\right.\right.$ $\left.\left(\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{8} \mathrm{Br}_{3}\right)-\right]^{-22} \quad\left(\mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{10}\right)_{2} \mathrm{CoS}_{2} \mathrm{CH},{ }^{23} \quad o-\mathrm{B}_{10} \mathrm{Br}_{2} \mathrm{H}_{8^{-}}$ $\mathrm{C}_{2} \mathrm{H}_{2},{ }^{26} \quad o-\mathrm{B}_{10} \mathrm{H}_{10}\left(\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Br}_{2},{ }_{2}{ }^{27} \quad m-\mathrm{B}_{10} \mathrm{Br}_{2} \mathrm{H}_{8} \mathrm{C}_{2} \mathrm{H}_{2},{ }^{28} \quad\right.$ and
(26) J. A. Potenza and W. N. Lipscomb, Inorg. Chem., 5, 1471 (1966). (27) D. Voet and W. N. Lipscomb, ibid., 3, 1679 (1964).
(28) H. Beall and W. N. Lipscomb, ibid., 5, 874 (1967).
$o-\mathrm{B}_{10} \mathrm{Cl}_{8} \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{H}_{2} .{ }^{29}$ The average value for $\mathrm{C}-\mathrm{C}$ bonds in the $\left(3,4^{\prime}\right)-\left[\left(\mathrm{CH}_{8}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{Ni}^{\mathrm{IV}}$ icosahedra may be somewhat misleading since the $\mathrm{C}\left(1^{\prime}\right)-\mathrm{C}\left(2^{\prime}\right)$ bond length of $1.717 \pm 0.015 \AA$ appears to be significantly longer than the more "normal" $\mathrm{C}(1)-\mathrm{C}(2)$ distance of $1.636 \pm$ $0.013 \AA$.

Within the triangular faces of the icosahedra, the 57 independent $\mathrm{B}-\mathrm{B}-\mathrm{B}$ bond angles have an average value of $60.0 \pm 1.7^{\circ}$. The $16 \mathrm{C}-\mathrm{B}-\mathrm{B}$ and $8 \mathrm{~B}-\mathrm{C}-\mathrm{B}$ angles average, respectively, $59.3 \pm 1.4^{\circ}$ and $61.5 \pm$ $1.4^{\circ}$, while the $6 \mathrm{C}-\mathrm{C}-\mathrm{B}$ and the $3 \mathrm{C}-\mathrm{B}-\mathrm{C}$ angles are $60.4 \pm 1.3^{\circ}$ and $59.2 \pm 2.1^{\circ}$. Angles of icosahedral faces involving the nickel atom are all lower, due to the greater Ni-B or Ni-C distance as compared with B-B, $\mathrm{B}-\mathrm{C}$, and $\mathrm{C}-\mathrm{C}$ bond lengths. The $\mathrm{C}-\mathrm{Ni}-\mathrm{C}, \mathrm{C}-\mathrm{Ni}-\mathrm{B}$, $\mathrm{B}-\mathrm{Ni}-\mathrm{B}$ angles average $43.5 \pm 0.4^{\circ}, 47.5 \pm 1.1^{\circ}$, and $50.0 \pm 1.3^{\circ}$, respectively. This results in a corresponding increase in average $\mathrm{Ni}-\mathrm{C}-\mathrm{C}\left(68.3 \pm 1.4^{\circ}\right)$, Ni-C-B $\left(63.7 \pm 1.8^{\circ}\right), \mathrm{Ni}-\mathrm{B}-\mathrm{C}\left(68.9 \pm 2.0^{\circ}\right)$, and $\mathrm{Ni}-\mathrm{B}-\mathrm{B}$ $\left(65.0 \pm 1.2^{\circ}\right)$ angles.

The average values of angles around the pentagonal rings are all consistent with those expected on the basis of distortions due to insertion of carbon atoms into the icosahedral framework, the protrusion of the nickel vertex, and the tilt of the $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}{ }^{2-}\right]$ ligands relative to one another. As with angles around the triangular faces, they are in good agreement with the values reported for similar compounds. ${ }^{17-18,20,22-23,26-29}$
The $\mathrm{CH}_{3}-\mathrm{C}-\mathrm{C}$ angles are all within $5^{\circ}$ of their average value of $117.2 \pm 3.2^{\circ}$, while $\mathrm{CH}_{8}-\mathrm{C}-\mathrm{B}$ angles range from $113.3 \pm 0.8^{\circ}$ to $127.2 \pm 0.8^{\circ}$ and average 119.7 $\pm 4.7^{\circ}$. The $\mathrm{CH}_{3}-\mathrm{C}-\mathrm{Ni}$ angles are somewhat smaller,

Table VIII. Intermolecular Contacts ( $\leq 3.5 \AA$ ) between $\left(3,4^{\prime}\right)-\left[\left(\mathrm{CH}_{8}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right]_{2} \mathrm{~N}^{1 \mathrm{~V}}$ Molecules

averaging $115.8 \pm 3.7^{\circ}$. There appear to be no significant distortions of the methyl groups from positions predicted from an idealized icosahedral geometry. Individual $\mathrm{C}-\mathrm{CH}_{3}$ bond lengths are: $\mathrm{C}(1)-\mathrm{CH}_{3}(1)=$ $1.553 \pm 0.014 \AA, \mathrm{C}(2)-\mathrm{CH}_{3}(2)=1.547 \pm 0.014 \AA$, $\mathrm{C}\left(1^{\prime}\right)-\mathrm{CH}_{3}\left(1^{\prime}\right)=1.511 \pm 0.014 \AA, \mathrm{C}\left(2^{\prime}\right)-\mathrm{CH}_{3}\left(2^{\prime}\right)=$ $1.577 \pm 0.017 \AA$. The average value of $1.547 \pm 0.028$ $\AA$ is not significantly different from the $\mathrm{C}\left(\mathrm{sp}^{3}\right)-\mathrm{C}\left(\mathrm{sp}^{3}\right)$ distance of $1.5445 \AA$ in diamond. ${ }^{30}$

## Intermolecular Contacts

The packing of (3,4 ) $\mathrm{H}\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~B}_{9} \mathrm{C}_{2} \mathrm{H}_{9}\right] \mathrm{Ni}^{\text {IV }}$ molecules within the unit cell is shown in Figure 2, which shows the view down $c$. Enantiomers are related to one another by an n -glide plane at $y=0.25$, and by centers of symmetry at ( 0 or $0.5,0$ or $0.5,0$ or 0.5 ).

The individual molecules are separated by normal van der Waals distances. Quantitative data on intermolecular contacts are shown in Table VIII. Closest approaches (of each type) are methyl carbon $\cdots$ hydrogen $=3.17$, boron $\cdots$ hydrogen $=3.34$, and hydrogen $\cdots$ hydrogen $=2.65 \AA$. It should be emphasized, however, that hydrogen atoms of the methyl groups have not been included in these calculations.

# Crystal and Molecular Structure of Bis-(3)-1,7-dicarbollylnickelate(II) Dianion 

Richard M. Wing<br>Contribution from the Department of Chemistry, University of California, Riverside, California 92502. Received July 2, 1969

#### Abstract

The crystal and molecular structure of $\left[\mathrm{CH}_{3} \mathrm{~N}_{\left.\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{3} \mathrm{NCH}_{3}\right]\left[\mathrm{Ni}\left(\text { neo }-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)_{2}\right] \text { has been determined }}\right.$ from a single-crystal X-ray diffraction study. The orthorhombic cell Fdd2 with $a_{0}=16.95$ (3), $b_{0}=24.52$ (7), and $c_{0}=11.63$ (4) $\AA$ contains only eight formula units ( $\rho=1.30 \mathrm{~g} / \mathrm{cm}^{3}$ ); thus both the organic dication and carbametallic dianion are crystallographically required to possess twofold axes of symmetry. The structure was solved using 622 unique nonzero reffections collected by a film method, and refined by least-squares techniques to a final $R$ factor of $10.5 \%$ based on $F$. While the carborane cages in the previously reported bis-(3)-1,2-dicarbollylnickelate(II) ion were grossly slipped with respect to one another to give an allyl-like structure, that distortion is nearly absent in the compound reported here. Although the (3)-1,7- and (3)-1,2-dicarbollide ions have the same symmetry, the atom charges in the former are believed to be more uniformly distributed. Thus, it appears that ligand asymmetry is a definite factor in the stereochemistry of the electron-rich metallobisdicarbollyls. A further feature of the structure is that the carborane cages are not related by a center of symmetry but, rather, have taken on an intermediate rotamer configuration. Although the $\mathrm{N}, \mathrm{N}$ '-dimethyltriethylenediammonium ion possesses three different twofold axes of symmetry, none of them was found to lie along a crystallographic twofold axis. Thus, for no obvious reason, the organic dication is disordered.

Alarge number of transition metal derivatives of the (3)-1,2-dicarbollide ion have been synthesized and structurally characterized by single-crystal X-ray diffraction studies. ${ }^{1}$ The stereochemistry of these compounds is of two distinct forms.

First, as exemplified by $\left[\pi-\mathrm{C}_{5} \mathrm{H}_{5}\right] \mathrm{Fe}\left[\pi(3)-1,2-\mathrm{C}_{2}-\right.$ $\left.\mathrm{B}_{9} \mathrm{H}_{11}\right],{ }^{2}$ there are symmetrical $\pi$-sandwich structures

[^3]which are extant when the metal in its "formal" valence possesses seven or fewer $d$ electrons.
Second, for those compounds which formally contain $\mathrm{d}^{8}$ or $\mathrm{d}^{9}$ metal ions, a slipped $\pi$-sandwich or $\pi$-allyl stereochemistry is observed. ${ }^{3}$

A part of a continuing effort to learn more about the distortions in the electron-rich ( $\mathrm{d}^{7}-\mathrm{d}^{9}$ ) series of compounds, the structure determination of the $\mathrm{Ni}^{2+}\left(\mathrm{d}^{8}\right)$ complex of (3)-1,7-dicarbollide ion was undertaken.
