# The Heats of Combustion and Strain Energies of Bicyclo[n.m.0]alkanes 

Sho-ju Chang, ${ }^{12}$ Donal McNally, Shahrokh Shary-Tehrany, Sister Mary James Hickey, ${ }^{\text {1b }}$ and Richard H. Boyd ${ }^{\text {lc }}$<br>Contribution from the Department of Chemical Engineering and Division of Materials Science and Engineering, University of Utah, Salt Lake City, Utah 84112. Received September 9, 1969

#### Abstract

The heats of combustion, vapor pressures, and liquid heat capacities of a number of bicyclic alkanes have been determined. The derived liquid and gas heats of formation in kilocalories mole ${ }^{-1}$ at $25^{\circ}$ are as follows: cis-bicyclo[3.1.0]hexane, $1.3 \pm 0.7,9.3 \pm 0.8$; cis-bicyclo[4.1.0]heptane, $-8.7 \pm 0.8,0.4 \pm 1.0$; cis-bicyclo[5.1.0]octane, $-14.2 \pm 0.5,-3.8 \pm 0.7$; cis-bicyclo[6.1.0]nonane, $-19.4 \pm 0.8,-7.6 \pm 1.0$; cis-bicyclo[4.2.0]octane, $-16.3 \pm 0.8,-6.1 \pm 1.1$; cis-bicyclo[3.3.0]octane, $-32.6 \pm 0.3,-22.3 \pm 0.5$; trans-bicyclo[3.3.0]octane, -26.1 $\pm 0.4,-15.9 \pm 0.6$; cis-bicyclo[5.3.0]decane, $-43.9 \pm 0.9,-31.1 \pm 1.2$. Experimental strain energies are derived from group contributions. Strain energies and geometries are also calculated by energy minimization with a set of transferable valence force potential functions. The agreement of calculated and experimental strain energies is satisfactory. The gas phase thermodynamic functions (free energy and enthalpy functions, heat capacity, and entropy) are also calculated.

In view of the great interest in recent years in the chemistry of strained cyclic hydrocarbons, studies of molecular properties and structure of such compounds are greatly in need. Of particular importance is the desirability of obtaining heats of formation from which empirical strain energies may be derived. It is the purpose of the present work to study an important family of strained ring compounds, the [n.m.0] bicyclic alkanes. The heats of formation cia oxygen combustion calorimetry of a number of such compounds have been measured in this work to arrive at strain energies.
The heats of formation of this family of hydrocarbons provide an important testing ground for calculation of molecular properties by energy minimization using transferable empirical valence force potential functions. In this work we have also made such calculations for the compounds measured and the other appropriate cycloalkanes for which data exist.
The compounds measured are cis-bicyclo[3.1.0]hexane, cis-bicyclo[4.1.0]heptane, cis-bicyclo[5.1.0]octane, cis-bicyclo[6.1.0]nonane, cis-bicyclo[4.2.0]octane, cis-

[^0]bicyclo[3.3.0]octane, trans-bicyclo[3.3.0]octane, and cisbicyclo[5.3.0]decane.

## Experimental Section

Compounds Studied. The four cyclopropane ring containing compounds had been synthesized by the Simmons-Smith reaction $^{2}$ and were furnished to us by Dr. Simmons. Bicyclo[4.2.0]octane was synthesized by us by photolysis of cycloocta-1,3-diene ${ }^{3}$ in benzene followed by hydrogenation. cis- and trans-bicyclo[3.3.0]octane were synthesized in Professor N. L. Allinger's laboratory at Wayne State University and the details are given in the M.S. Thesis of one of us (M. J. H.). ${ }^{4}$ cis-Bicyclo[5.3.0]decane was made by hydrogenation (at 1 atm catalyzed by reduced platinum oxide) of a commercial sample of azulene (Aldrich Chemical Co.) that had been purified by sublimation by us. The compounds were either purified by gas-liquid chromatography (glc) or showed no extraneous peaks by glc after distillation.

Heats of Combustion. These were measured with a calorimeter and techniques previously described. ${ }^{5.6}$ A G-2 Mueller bridge (Leeds and Northrup $8069-B$ ) was used for the resistance ther-

${ }^{a} M_{\mathrm{s}}=$ weight of sample ( g in air $v s . \mathrm{SS}$ ); $M_{\mathrm{f}}=$ weight of fuse ( g in air $v s . \mathrm{SS}$ ); $M_{\mathrm{m}}=$ weight of "Mylar" ( g in air $v s . \mathrm{SS}$ ); $\Delta R=\mathrm{cor}-$ rected temperature rise (ohms); $Q_{i}=$ energy of ignition (calories); $Q_{0}=$ correction for soot traces (calories); $Q_{a}=$ nitric acid correction (calories); $Q_{\text {std }}=$ correction to standard states (Washburn) $;-\Delta E_{\mathrm{c}}{ }^{\circ}=\left(\epsilon \Delta R+Q_{\mathrm{c}}-Q_{\mathrm{f}}-Q_{\mathrm{m}}-Q_{\mathrm{i}}-Q_{\mathrm{a}}-Q_{\mathrm{std}}\right.$ )/ $/ M_{\mathrm{s}}$ (cal g-1 in air vs. SS) where $\epsilon$, the energy equivalent of the calorimeter, was $8929.0 \pm 1.7 \mathrm{cal} \mathrm{ohm}^{-1}$ for the first six runs, and $9034.0 \pm 1.59 \mathrm{cal}^{\mathrm{cah}}{ }^{-1}$ for the final three runs which were carried out after equipment modifications; $Q_{\mathrm{m}}=$ energy of Mylar combustion was calculated using combustion energies of $-5476.1 \mathrm{cal} \mathrm{g}^{-1}$ and $-5483.14 \mathrm{cal} \mathrm{g}^{-1}$ for the first six and last three runs, respectively; $Q_{\mathrm{f}}=$ energy of combustion of fuse was calculated using a value of $4184 \mathrm{cal}^{-1}$ for the combustion energy of cotton thread. ${ }^{b}$ When weights are corrected to vacuum.
mometry. The "Mylar" bag technique was used to confine the samples. ${ }^{7}$ A set of typical results is shown in Table I.
Vapor-Pressure Measurements. In order to correct heats of combustion to the vapor phase, heats of vaporization were determined from vapor pressures. A "boiling-point" method employing a semimicro ebulliometer was used. ${ }^{8}$ The liquid was boiled at a fixed pressure and the temperature of the boiling liquid measured. The results of fitting eq 1 to the data are presented in Table II. In

$$
\begin{equation*}
\log P=A / T+B+C \log T \tag{1}
\end{equation*}
$$

a number of cases the temperature range measured was small enough that the $C \log T$ term was not used. Heats of vaporization were determined from eq 1 without correction for vapor imperfection or liquid volume and thus are given by

$$
\begin{equation*}
\Delta H_{\mathrm{vap}}=R(-2.303 A+C T) \tag{2}
\end{equation*}
$$

Where liquid heat capacity data were available it was combined with the calculated gas phase heat capacities and correction of the heat of vaporization was made from the temperature range of the vapor pressure measurements to $25^{\circ}$.

Table II. Values of Constants $A, B$, and $C$ from the Vapor Pressure Curves of the Compounds ${ }^{a}$

and trans compounds, respectively. Their values are about 1.5 kilocalories more negative than ours, but the heat of isomerization from cis to trans is in good agreement.

## Discussion

In pursuit of our goals of measuring and interpreting the strain energies of bicycloalkanes, we first present for the bicycloalkanes studied here and those in the literature a table (Table $V$ ) of experimental strain energies defined in the conventional manner. That is, they are defined as the difference between the experimental heat of formation and a predicted one based on group contributions for heats of formation of unstrained alkanes. Thus, the experimental strain energy is defined as

$$
\begin{array}{r}
S E\left(\text { exptl, } 298^{\circ} \mathrm{K}\right)=\Delta H_{\mathrm{f}}^{\circ}\left(\text { exptl, } 298^{\circ} \mathrm{K}\right)- \\
\sum \Delta H_{\mathrm{f}}^{\circ}(\text { group }) \tag{3}
\end{array}
$$

For the right-hand terms we have used a scheme worked out here (see below) that is similar to and inspired by that of Schleyer, et al. ${ }^{10}$ Also included in Table $V$ is a simple but naive approach to the interpretation of strain. The sum of the experimental strain energies of component monocyclic rings is compared with the experimental strain energy of the bicyclic hydrocarbon. This approach will be more or less in error since the conformations of the fused rings will, in general, be different from the separate rings and a torsional interaction will be missing from the fused system. Since the former will increase the strain energy and the latter lower it, they will be somewhat compensatory. It is seen in Table $V$ that fairly substantial deviations from

Figure 1. Notation for angles used in Table VI.
lations on strained hydrocarbons with considerable success but has used a $\mathrm{C}-\mathrm{C}-\mathrm{C}$ bending function that corresponds to the force constant becoming smaller with decreasing bond angle. The senior author (R. H. B.) feels that the lack of definite spectroscopic evidence for this in cyclopentane and the fact that the force constant in cyclobutane is much higher than in cyclopentane or cyclohexane mitigates strongly against this approach. We have kept this force constant independent of angle and consider the cyclobutane and cyclopropane rings to be special electronic systems (with their own force constants) which can be incorporated into more complicated ring systems (see below).

We have taken the view that the valence functions used should lead to results that are simultaneously consistent insofar as possible with the three general properties of heats of formation, molecular geometry, and vibrational frequencies. It is our belief that this overall view is vital even at the sacrifice of some detailed agreement in any one of these areas alone. One of us has developed ${ }^{20}$ an energy minimization procedure that appears to be efficient in terms of computation time and performs a vibrational analysis on the final geometry. Thus the potential functions may be adjusted to fit experimental results of all of the three kinds. Lifson and Warshel ${ }^{21}$ have used a similar approach in calculations on the $\mathrm{C}_{5}-\mathrm{C}_{10}$ cycloalkanes and obtained good results. However, no other strained molecules were included. We have developed a model and set of parameters that appear to be reasonably successful in calculations on a variety of unstrained and strained hydrocarbons and have reported them in part. ${ }^{22}$ A somewhat more elaborate version is presented here in Table VI. Figure 1 shows the notation used for the angles in Table VI.

The model used is elaborated upon below.
(a) It is assumed that the molecular energy can be empirically described as a sum of equilibrium intrinsic bond energies (or group contributions) and energies of bond stretching, bending, and twisting plus nonbonded interaction energies.
(b) As with a number of other workers, the torsional barrier is assumed to be an inherent barrier in a carboncarbon single bond, described by a cosine potential plus nonbonded interactions between the substituents on each carbon.
(c) The same nonbonded interactions as in b are used between all atoms not involved in bond bending, stretching, or twisting. The nonbonded potentials used

[^2]Table VI. Potential Functions Used for Calculations on Alkanes ${ }^{a}$

| Valence Force Potential (VF) Bond Stretching (harmonic function) |  |  |
| :---: | :---: | :---: |
|  | $k_{\text {r }}$ | $R_{0}$ |
| C-H |  |  |

Rossini, "Selected Values of Physical and Thermodynamic Properties of Hydrocarbons and Related Compounds," Carnegie Press, Pittsburgh, Pa., 1953. ${ }^{b}$ From calculated frequencies of ref 25. ${ }^{c}$ Computed using values of first three columns and eq 6 of text. ${ }^{d}$ Calculated using values of Table VII for $E_{\mathrm{I}}{ }^{*}$, the values of column 11 for $D E+N B$ and eq 7 of text. "Calculated in this work using parameter set VF of Table VI. ${ }^{f}$ From the values of Table VII. © W. D. Good, J. Chem. Thermodyn., 2, 237 (1970).
(d) The force constants for stretching and bending are taken from the work of Snyder and Schachtschneider ${ }^{25}$ but adjusted iteratively by sucessive linear interpolation to fit the frequencies of cyclohexane. This was necessary to take into account the effects of including nonbonded interactions and the torsional barrier representation used here. The $\mathrm{C}-\mathrm{C}-\mathrm{C}$ bending constant was chosen to fit the $E_{g}$ and $E_{u}$ frequencies of cyclohexane but was biased to some extent by the heat of formation of cyclopentane.
(e) It is desirable to retain the concept of strain energy in discussions of molecular stability. However, energy minimization calculations do not give strain energies directly but rather the sum of bond deformation (stretching, bending, and twisting) energies plus the nonbonded interaction energies. Unstrained molecules will have appreciable deformation and nonbonded energies. We have worked out (Table VII) a set of group contributions to these for unstrained alkanes. We have followed Schleyer, et al., in including a skew methyl interaction as an additional group. This results in more consistent group representation of the deforma-

[^3]tion and nonbonded energies. Table VIII compares the deformation and nonbonded energies for a variety of alkanes calculated by energy minimization using the parameters of Table VI with the group contributions. These group contributions are to be subtracted from calculated deformation and nonbonded energies in strained molecules to arrive at strain energies. We further assume that the strain energy calculated in this way is appropriate to the molecule in a hypothetical motionless (with respect to translation, rotation, and vibration) state, or
\[

$$
\begin{equation*}
S E^{*}(\text { calcd })=D E+N B-\sum(D E+N B)_{\text {group }} \tag{5}
\end{equation*}
$$

\]

where the asterisk refers to the hypothetical motionless state, DE refers to the deformation energy of a molecule (due to bond stretching, bending, and twisting from "natural values"), and NB refers to the sum of nonbonded energies of a molecule.
(f) The calculated strain energy in eq 5 in the hypothetical motionless state is not, in general, appropriate for comparison with the experimental strain energy of eq 3 at $298^{\circ} \mathrm{K}$. It is known that experimental strain energies are significantly dependent on temperature
and on zero-point energy effects. ${ }^{26,27}$ Taking advantage of the fact that the energy minimization procedure provides calculated thermodynamic functions and zeropoint energies, a calculated strain energy at $298^{\circ} \mathrm{K}$ may be arrived at. The experimental molecular energy (energy of atomization, $E_{a}^{*}$ ) in the hypothetical motionless state of a $\mathrm{C}_{a} \mathrm{H}_{b}$ hydrocarbon (where $a=$ number of carbons in a $\mathrm{C}_{a} \mathrm{H}_{b}$ alkane and $b=$ number of hydrogens in a $\mathrm{C}_{u} \mathrm{H}_{b}$ alkane) may be expressed as

$$
\begin{align*}
& E_{a}{ }^{*}(\text { exptl })=-\Delta H_{\mathrm{f}}{ }^{\circ}\left(\operatorname{exptl}, 298^{\circ} \mathrm{K}\right)+ \\
& \left(H_{298^{\circ} \mathrm{K}}-H_{0}{ }^{\circ}\right)+Z P E+170.890 a+ \\
& 52.090 b-5 / 2(a+b) R T_{298^{\circ} \mathrm{K}} \tag{6}
\end{align*}
$$

where the heats of atomization of C (graphite) and $\mathrm{H}_{2}$ (g) at $298^{\circ} \mathrm{K}$ have been taken from Stull and Sinke ${ }^{28}$ and $H_{298{ }^{\circ} \mathrm{K}}-H_{0}{ }^{\circ}$ and $Z P E$ are the enthalpy and zeropoint energies of the compound. From section a above it follows that

$$
\begin{equation*}
E_{a}^{*}(\text { calcd })=\sum E_{1}^{*}(\text { group })-(D E+N B) \tag{7}
\end{equation*}
$$

where the $E_{1}{ }^{*}$ are a set of intrinsic bond energies or group contributions. Comparison of eq 6 and 7 for unstrained alkanes allows a set $E_{\mathrm{I}} *$ (group) to be worked out (Table VII). We then define

$$
\begin{array}{r}
-S E^{*}(\text { exptl })=E_{a}^{*}(\text { exptl })-\sum E_{1}^{*}(\text { group })+  \tag{8}\\
\sum(D E+N B)_{\text {group }}
\end{array}
$$

Using the analogy of eq 6 for calculated values we can arrive at an expression for the calculated heat of formation at $298^{\circ} \mathrm{K}$ as

$$
\begin{gather*}
\Delta H_{\mathrm{f}}{ }^{\circ}\left(\text { calcd, } 298^{\circ} \mathrm{K}\right)=-\sum E_{\mathrm{I}}^{*}(\text { group })+ \\
(D E+N B)+\left(H_{298^{\circ} \mathrm{K}}{ }^{\circ}-H_{0}{ }^{\circ}\right)+ \\
Z P E+170.890 a+52.090 b- \\
{ }^{5} / 2(a+b) R T_{298^{\circ} \mathrm{K}} \tag{9}
\end{gather*}
$$

Thus we may define

$$
\begin{aligned}
& S E\left(\text { calcd }, 298^{\circ} \mathrm{K}\right)=\Delta H_{\mathrm{f}}^{\circ}\left(\text { calcd, } 298^{\circ} \mathrm{K}\right)- \\
& \sum \Delta H_{\mathrm{f}}^{\circ}(\text { group })
\end{aligned}
$$

We are then in a position to compare calculated and experimental strain energies both at room temperature $(S E)$ and in the hypothetical motionless state ( $S E^{*}$ ) if a set of $\Delta H_{\mathrm{f}}{ }^{\circ}$ (group) is determined. First, however, we note that in arriving at $E_{a}^{*}$ (exptl) (eq 6) for computation of $S E^{*}$ (exptl) (eq 8) it will usually be necessary, as in the work reported here on bicyclo compounds, to use calculated values of $H_{298 \mathrm{~K}}{ }^{\circ}-H_{0}{ }^{\circ}$ and $Z P E$. Since these will be the same calculated values as in eq 9 we may write in this case

$$
\begin{align*}
& S E^{*}(\text { exptl })=S E^{*}(\mathrm{calcd})+ \\
& \Delta H_{\mathrm{f}}^{\circ}(\text { exptl })-\Delta H_{\mathrm{f}}{ }^{\circ}(\text { calcd }) \tag{11}
\end{align*}
$$

A set of group contributions to $\Delta H_{\mathrm{f}}{ }^{\circ}$ has been arrived at by determining group contributions to each of the appropriate terms in eq 9. $E_{1}^{*}$ (group) and ( $D E+$ $N B)_{\text {group }}$ have already been discussed under (e) above and are listed in Table VII. Enthalpy groups were deduced from the enthalpies calculated for unstrained alkanes

[^4]by energy minimization using the parameters of Table VI. The experimental values were not used since, as stressed by Schleyer, et al., ${ }^{10}$ these reflect a mixture of conformations in a number of cases. The calculated values represent the single most stable conformation. It is to be observed in Table VIII that where gauche isomers can exist the calculated enthalpies are lower than the experimental. The zero-point energy groups were determined from the zero-point energies derived from the frequencies of Snyder and Schachtschneider ${ }^{25}$ which we regard as "experimental." Comparison of the zero-point energies from experiment, calculated from energy minimization and from groups, are compared in Table VIII. Combining the group contributions of $E_{1}{ }^{*},(D E+N B),\left(H_{298 \mathrm{~K}}{ }^{\circ}-H_{0}{ }^{\circ}\right)$, and $Z P E$ through eq 9 results in the group contributions to $\Delta H_{\mathrm{f}}{ }^{\circ}$ listed in Table VII. In defining the strain energies of cyclic compounds we have not included any gauche interaction group in either $\Delta H_{\mathrm{f}}{ }^{\circ}$ (group) or ( $D E+$ $N B)_{\text {group. }}$. Thus, such interactions appear as strain. It is a matter of taste then to say that noncyclic alkanes containing similar skew methyl interactions are not strained but cyclic compounds containing gauche conformations are. Of course, any definition of strain is arbitrary in that the strain depends on the reference structures used in the definition. The important requirement of conformational calculations is the ability to calculate the actual heat of formation or binding energy.

${ }^{a}$ K. Kuchitsu, J. Chem. Phys., 49, 4456 (1968). ${ }^{b}$ K. A. Strong and R. M. Brugger, ibid., 47, 421 (1967). ${ }^{\circ}$ See ref 12 for references. ${ }^{d}$ T. Ueda and T. Shimanouchi, J. Chem. Phys., 49, 470 (1968). e M. Davis and O. Hassel, Acta Chem. Scand., 17, 1181 (1963). $f$ E. L. Eliel, N. L. Allinger, S. J. Angyal, and G. A. Morrison, "Conformational Analysis," Interscience Publishers, New York, N. Y., $1965, ~ p 44$.

If it is felt that $\left(H_{298 \mathrm{~K}}{ }^{\circ}-H_{0}{ }^{\circ}\right)$ and $Z P E$ are adequately represented by group contributions; the distinction between $S E^{*}$ and $S E\left(298^{\circ} \mathrm{K}\right)$ is dropped and eq 5 used for strain energy in general. Also, a simpler representation for the heat of formation predicted by energy minimization results

$$
\begin{align*}
\Delta H_{\mathrm{f}}{ }^{\circ}(\text { calcd })= & \Delta H_{\mathrm{f}}{ }^{\circ}(\text { group })+ \\
& (D E+N B)_{\text {calcd }}-(D E+N B)_{\text {group }} \tag{12}
\end{align*}
$$

However, in this work, since we are interested in investigating the adequacy of this approach for cyclic compounds, we have retained the distinction and eq 9 is used to arrive at $\Delta H_{\mathrm{f}}{ }^{\circ}$ (calcd) and to define $S E$ (calcd, $298^{\circ} \mathrm{K}$ ), through eq 10 . Equations 5 and 11 are used tor $S E^{*}$ (calcd) and $S E^{*}$ (exptl), respectively.

Several comments on the results in Table VIII are in order. First, $H_{298 \mathrm{~K}}{ }^{\circ}-H_{0}{ }^{\circ}$ and $Z P E$ for noncyclic alkanes are adequately represented by groups. Thus, in agreement with other workers we find no necessity for making such corrections and room-temperature bond energy schemes are adequate. Second, the agreement between $E_{\mathrm{a}} *$ (exptl) and $E_{\mathrm{a}} *$ (calcd) is satisfactory and is a noticeable improvement over schemes based on only the first four groups of Table VII (Franklin's method ${ }^{29}$ for heats of formation). This is significant since this improvement is the result of superimposing the nonbonded interaction energies used here on intrinsic group or bond energies and does not depend on ad hoc conformational corrections such as the skew methyl correction we have used for the group contributions to the nonbonded interactions.
(g) The equilibrium bond angle for $\mathrm{C}-\mathrm{C}-\mathrm{C}$ was taken to be $111.0^{\circ}$ which leads to calculated values in linear alkanes of about $112.0^{\circ}$. The smaller rings ( $n=3,4$ ) have to be considered as electronic systems different from the other alkanes and special parameters assigned to them. These are then used with these parameters to build multicyclic rings. The same group contributions to the intrinsic bond energies were used and a correction factor for the ring added. In cyclopropane the correction represents $S E^{*}$ but in cyclobutane due to the choice of equilibrium angles it does not. In cyclobutane, the equilibrium $\mathrm{C}-\mathrm{C}-\mathrm{C}$ angle was taken to be $90^{\circ}$. There is no special significance to this angle except that particularly simple analytical
(29) J. L. Franklin, Ind. Eng. Chem., 41, 1070 (1949).
formulas result that connect the dihedral angles, the $\mathrm{C}-\mathrm{C}-\mathrm{C}$ force constant, the torsional force constant, effective out-of-plane deformation force constant, and the barrier to inversion. In building multicyclic rings using $n=3,4$ rings an ambiguity results in selecting equilibrium angles at the juncture points. The arbitrary rule was followed that the equilibrium angles at the juncture points that are exterior to the rings are considered to be that of the smaller ring involved.

${ }^{a}$ Units are calories and ${ }^{\circ} \mathrm{K}$. Values in parentheses are experimental or calculated from spectra from indicated references. Calculated values use valence force set of Table VI, unless indicated otherwise as UB (Urey-Bradley). ${ }^{b} \mathrm{H} . \mathrm{H}$. Gunthard, R. C. Lord, and T. K. McCubbin, Jr., J. Chem. Phys., 25, 768 (1956). ${ }^{c}$ The ring puckering energy levels of T. Ueda and T. Shimanouchi, ibid., 49, 470 (1968), were used with our other calculated frequencies and geometry. d Experimental value of G. W. Rathjens and W. D. Gwinn, J. Amer. Chem. Soc., 75, 5629 (1953). $\quad$ e R. C. Lord and I. Nakagawa, J. Chem. Phys., 39, 2951 (1963). f Values in parentheses are those tabulated by J. E. Kilpatrick, K. S. Pitzer, and R. Spitzer, J. Amer. Chem. Soc., 69, 2483 (1947). A $q_{0}$ value of $0.38 \AA$ from our calculated structure was used ( $c f$. $\left.q_{0}=0.47 \AA\right) ;$ K. S. Pitzer and W. E. Donath, ibid., 81, 3213 (1959). The second value of the zero-point energy is that reported in ref 26. ${ }^{\circ}$ Values in parentheses are those tabulated by C. W. Beckett, K. S. Pitzer, and R. Spitzer, ibid., 69, 2488 (1947). ${ }^{h}$ From ref $25 .{ }^{i}$ This molecule has one calculated frequency that is nearly zero. The pseudorotator value of $1 / 2 R$ was given to $\left(H^{\circ}-H_{0}{ }^{\circ}\right) / T$ and $C_{p}{ }^{\circ}$ but no speculation regarding the entropy was made. ${ }^{i}$ This molecule has two nearly zero frequencies that were assigned pseudorotation values. See $i$ above. ${ }^{k}$ Values in parentheses are from T. Miyazawa and K. S. Pitzer, J. Amer. Chem. Soc., 80, 60 (1958).

It was hoped that no special assumptions concerning the $n=5$ ring need be made but it turned out to be necessary to assign the value of the $\mathrm{C}-\mathrm{C}-\mathrm{C}$ angle as $109.5^{\circ}$. This change is not particularly critical for cyclopentane itself but is necessary to obtain agreement for the heat of formation of several compounds containing $n=5$ rings.
(h) The valence force potentials used here led to good distributions of vibrational frequencies for calculation of the thermodynamic functions and zero-point energy. Since no interaction constants are used the detailed agreement with vibrational frequencies is not impressive. Snyder and Schachtschneider ${ }^{25}$ used transferable interaction constants and obtained good agreement of calculated and experimental frequencies. However, they also obtained fairly good agreement ${ }^{30}$ by superimposing a Urey-Bradley force field on the valence force. In order to obtain better detailed agreement with spectroscopic results we have derived an alternative set of parameters by using the partial Urey-Bradley field to introduce interactions between stretching and bending. The Urey-Bradley constants and the angle force constants of Snyder and Schachtschneider ${ }^{30}$ were modified to take into account the nonbonded potentials used here. The calculated spectra are noticeably improved (see Table IX), particularly the $E_{g}$, $\mathrm{A}_{2 \mathrm{u}}$, and $\mathrm{E}_{\mathrm{u}} \quad \mathrm{CH}_{2}$ deformation frequencies. Strain energy calculations were made (designated UB in the tables) for many of the compounds using this field and are very similar to results using the valence force field (VF). In summary, we might say that the VF field can be used with its fewer interactions for structural and thermodynamic calculations. However, if better spectral agreement is desired the UB field with more interactions is probably to be preferred.

A variety of miscellaneous properties calculated with the VF parameters of Table VI are summarized in Table X.

The heats of formation of the bicycloalkanes form a very critical testing ground for any set of parameters for the calculation of hydrocarbon properties. We are, therefore, especially interested in the comparison between calculated and experimental strain energies of these compounds. This comparison is made in Table XI. It is seen that the agreement is, in general, gratifying and the strain energies can be calculated

[^5]with a typical deviation of about $1 \mathrm{kcal} \mathrm{mol}^{-1}$. A notable exception is trans-bicyclo[3.3.0]octane, where the calculated strain energy is over $6 \mathrm{kcal} \mathrm{mol}^{-1}$ greater than the experimental. We do not know the reason for the failure with this compound but it is unusual in that there is a large positive calculated $\mathrm{C}-\mathrm{C}-\mathrm{C}$ angle strain at the fusion points (see Figure 2). It may be that the

Figure 2. Calculated geometries of bicycloalkanes. Larger numbers aret orsional angles (based on eclipsed as 0 ); smaller numbers are CCC bond angles.
potential functions used do not adequately describe these large positive deformations. It is to be noticed in Table XI that the strain energies in the hypothetical motionless state are somewhat higher than at room temperature. It is evident that taking into account the effects of zero point and vibrational energies is important in predicting the strain energies of cyclic hydrocarbons at room temperature. The differences are not as great as previously found ${ }^{26,27}$ for cycloalkanes where the strain energies were based on reference structures containing mixtures of conformational isomers. However, there remains a real effect that results from the tendency of the enthalpy and zero-point energy groups derived from noncyclic structures to overestimate the values for cyclic compounds. Part of past difficulties in finding potential functions that simultaneously reproduce vibrational spectra and strain energies is due to using experimental strain energies that are too low because of the single conformation and vibrational effects above.

The calculated thermodynamic functions are given in Table XII and compared with experiment where possible. The thermodynamic functions are for the conformation calculated but in many cases there are, no doubt, several conformations of similar energy,
a situation that will have an appreciable effect on the entropy and free energy. The symmetry numbers and stereoisomeric pairs used in the entropy calculations are recorded in the table. The agreement with experimental values where the comparison can be made is excellent. We believe that the calculation of gas phase thermodynamic functions by a vibrational analysis using transferable potential functions with the minimum energy structure is now a very convenient and accurate way of predicting these quantities.

The calculated geometries are illustrated in Figure 2.

Acknowledgments. We are indebted to the U. S. Army Research Office (Durham) for financial support of this work. We are grateful to Dr. H. E. Simmons, Jr., Central Research Department, E. I. du Pont de Nemours Co. for furnishing the cyclopropanes, and to Professor N. L. Allinger of Wayne State University for his interest in the bicyclo[3.3.0]octanes and for providing the facilities for their synthesis. We express our appreciation to Professor P. v. R. Schleyer of Princeton University for communicating his work on goup contributions for strain energy definition to us.

# Generation, Rearrangement, and Interconversion of Hydrocarbons Related to Bullvalene ${ }^{1,2 a c}$ 

Maitland Jones, Jr., ${ }^{3}$ Steven D. Reich, and Lawrence T. Scott<br>Contribution from the Department of Chemistry, Princeton University, Princeton, New Jersey 08540. Received September 22, 1969

#### Abstract

Bicycio[4.2.2]deca-2,4,7,9-tetraene (8), cis- and trans-9,10-dihydronaphthalene ( 6 and 5), and cis-1phenylbutadiene (7) are formed on thermal decomposition of the salt of bicyclo[6.1.0]nona-2,4,6-triene-9-carboxaldehyde tosylhydrazone (3f). Similarly, cis-bicyclo[5.2.0]nona-2,4,8-triene (20), bicyclo[3.2.2]nonatriene (21), and bicyclo[4.2.1]nonatriene (19) are formed on thermal decomposition of the salt of bicyclo[5.1.0]octa-2,4-diene-8carboxaldehyde tosylhydrazone (18f). The proofs of structure of several of these hydrocarbons are described and a mechanism involving cleavage of an initially formed carbene to a diradical proposed. The conversion of 8 to bullvalene (1) on photolysis is described, as is the further photolysis of $\mathbf{1}$. The thermal conversions of several of these $(\mathrm{CH})_{10}$ 's to 6 are described.

The discovery ${ }^{4.5}$ that bullvalene (1) possessed the fully fluxional structure predicted ${ }^{6,7}$ has been one of the most stimulating of recent years. More or less parallel to the emerging chemistry of bullvalene has been the examination of the properties of molecules closely related in either an isomeric or conceptual sense. The unravelling of the structures and interrelationships of the various $(\mathrm{CH})_{10}$ 's has been a diverse and international effort and we describe here our part in it.

Our work began with the perhaps naive conception that the well known ring-expansion reaction of cyclopropylcarbenes ${ }^{9}$ could be used to add a $\mathrm{C}_{2} \mathrm{H}_{2}$ unit to cyclooctatetraene ${ }^{10}$ to produce the unknown (at

[^6]that time) bicyclo[6.2.0]deca-2,4,6,9-tetraene (2). ${ }^{11}$ The synthesis of the required carbene precursor proceeded through the ester $\mathbf{3 a}$ or $\mathbf{3 b}^{12-14}$ in several ways. In practice, the route through the alcohol has been most convenient in our laboratories. In the initial addition to cyclooctatetraene, two stereoisomers are formed.

    additivity can be present and that they are often in the direction of the strain being less than the sum of two rings.

    We now proceed to the more sophisticated method of using transferable potential functions and energy minimization to predict the heats of formation and other properties. ${ }^{11}$ A number of authors have developed potential functions for such calculations. Some of these have been designed for special purposes, such as prediction of simple alkane or polymer confor-
