

Figure 1. Correlation of computed valence states of butadiene (right) with those of two ethylene molecules (left).

Fock configuration. ${ }^{12}$ The errors in their computed vertical excitation energies are probably quite small, as are the errors for the other valence states $1^{3} \mathrm{~B}_{\mathrm{u}}$ and $1^{3} \mathrm{~A}_{\mathbf{g}}$. Being essentially doubly excited states, they are not expected to make significant contributions to either the optical or the electron impact spectra of butadiene, though the $2^{1} \mathrm{~A}_{g}$ state may be accessible in two-photon laser spectroscopy. These states, and particularly the $2^{1} \mathrm{~A}_{\mathrm{g}}$ state, may play a role in the photochemistry of butadiene. For example, the semiempirical calculations of van der Lugt and Oosterhoff ${ }^{13}$ indicate that an excited ${ }^{1} \mathrm{~A}_{\mathrm{g}}$ state is responsible for the cyclization of butadiene to cyclobutene; this state may be identified with the $2^{1} \mathrm{~A}_{\mathrm{g}}$ state. ${ }^{1}$

All the valence states of butadiene can easily be accounted for by a straightforward generalization of valence bond theory. ${ }^{1}$ Using a "molecules-in-molecules" or exciton approach, ${ }^{14}$ the ground and excited states of butadiene are described in terms of the electronic states of the two localized ethylenic subunits (Figure 1). From the two $\pi$-electron valence states of ethylene, the ground $\mathrm{N}\left(\pi^{2}\right)$ and excited triplet $\mathrm{T}\left(\pi \pi^{*}\right)$ states, a total of six states of butadiene can be constructed. With the two ethylenic units in the N state, the ground state of butadiene, denoted as $\mathrm{NN}\left(\mathrm{X}^{1} \mathrm{~A}_{\mathrm{g}}\right)$, is obtained. Two triplet states, $\mathrm{NT}\left({ }^{3} \mathrm{~B}_{\mathrm{u}}\right)$ and $\mathrm{NT}\left({ }^{3} \mathrm{~A}_{\mathrm{g}}\right)$, are obtained if one unit is in T and the other in N . In the absence of significant stabilization effects, their average excitation energy ( 4.24 eV for $1^{3} \mathrm{~A}_{\mathrm{g}}$ and $1^{3} \mathrm{~B}_{\mathrm{u}}$ in this calculation) is just the $\mathrm{N} \rightarrow \mathrm{T}$ excitation energy of ethylene (calculated as 4.22 eV ). With both ethylenic units in the T state, three states can be formed, $\mathrm{TT}\left({ }^{1} \mathrm{~A}_{\mathbf{g}}\right)$, $\mathrm{TT}\left({ }^{3} \mathrm{~B}_{\mathrm{u}}\right)$, and $\mathrm{TT}\left({ }^{5} \mathrm{~A}_{\mathrm{g}}\right)$. Their average excitation energy
(12) Several workers have noted the large effect of doubly excited configurations on the location of the $2^{1} \mathrm{~A}_{\mathrm{g}}$ state but did not realize that the resulting $2^{1} \mathrm{Ag}_{\mathrm{g}}$ state is not related to the $2^{1} \mathrm{Ag}_{\mathrm{g}}$ state obtained in a single-excitations-only CI calculation (the latter becoming the $3^{1} \mathrm{~A}_{\mathrm{g}}$ state in double-excitation $\mathrm{CI}^{1}$ ); see, e.g., J. Koutecky, J. Chem. Phys., 47, 1501 (1967), and references therein. Koutecky has pointed out that this state should be reachable by double-photon excitation from the ground state.
(13) W. Th. A. M. van der Lugt and J. Oosterhoff, J. Amer. Chem. Soc., 91, 6042 (1969).
(14) W. Moffitt, J. Chem. Phys., 22, 320 (1954); Y. Mori, Bull. Chem. Soc. Jap., 28, 291 (1955); R. S. Berry, J. Chem. Phys., 26, 1660 (1957).
should be approximately twice the $\mathrm{N} \rightarrow \mathrm{T}$ energy of ethylene, i.e., 8.44 eV . Correlating them with the calculated $2^{1} \mathrm{~A}_{\mathrm{g}}, 3^{3} \mathrm{~B}_{\mathrm{u}}$, and $1^{5} \mathrm{~A}_{\mathrm{g}}$ valence states of butadiene, we get $\Delta E_{\mathrm{sv}}=8.15 \mathrm{eV}$. The occurrence of such doubly excited states in conjugated systems is expected to be quite general. ${ }^{15,16}$

The diffuse $\pi$-electron states of butadiene can be constructed in a similar manner. With one ethylenic unit in the singlet $\mathrm{V}\left(\pi \pi^{*}\right)$ state we obtain the $\mathrm{NV}\left({ }^{1} \mathrm{~B}_{u}\right)$ and $\mathrm{NV}\left({ }^{1} \mathrm{~A}_{\mathrm{g}}\right)$ states of butadiene. In contrast to the valence states, however, the diffuse states are well represented by a single SCF configuration; delocalization is thus significant, and the simple generalized valence bond description is less appropriate for these states.
(15) K. Schulten and M. Karplus, Chem. Phys. Lett., 14, 305 (1972), and J. Michl and J. Downing, Proceedings of the Summer Research Conference on Theoretical Chemistry, Boulder, Colo., June 1972 (to appear) have reported low-lying doubly excited states obtained in semiempirical calculations on large conjugated systems. See also J. Downing, V. Dvořák, J. Kolc, A. Manzara, and J. Michl, Chem. Phys. Lett., 17, 70 (1972), and references therein.
(16) The occurrence of related states in benzene has recently been demonstrated, see P. J. Hay and I. Shavitt, to be submitted for publication.

## Molecular Structure of

## (1,7-Cyclododecadiyne)hexacarbonyldiiron.

Implications on the Alkyne Disproportionation Reaction Sir:

Addition of cyclic alkadiynes to transition metal complexes has produced some interesting intramolecular cyclization reactions in which complexed cyclobutadiene and cyclopentadiene derivatives are formed. ${ }^{1,2}$ In particular, the reaction of 1,7 -cyclododecadiyne (I) with $\mathrm{Fe}(\mathrm{CO})_{5}$ has produced two complexes, $\mathrm{C}_{12} \mathrm{H}_{16}$ $\mathrm{Fe}_{2}(\mathrm{CO})_{6}$ (major product) and $\mathrm{C}_{12} \mathrm{H}_{16} \mathrm{Fe}(\mathrm{CO})_{3}$ (trace). These compounds were originally formulated as II and III, respectively. ${ }^{16}$ We have determined the structure of the major product, ( 1,7 -cyclododecadiyne) $\mathrm{Fe}_{2}(\mathrm{CO})_{6}$, via X-ray diffraction techniques and have found its geometry to be not II but IV.

Crystal data for $\mathrm{C}_{12} \mathrm{H}_{16} \mathrm{Fe}_{2}(\mathrm{CO})_{6}$ : space group $P 3_{1}$ (trigonal, no. 144); ${ }^{3} \quad a=9.186$ (3), $c=18.604$ (6) $\AA$; $V=1359 \AA^{3} ; \rho_{\text {called }}($ based on $Z=3)=1.61 \mathrm{~g} \mathrm{~cm}^{-3}$,

$\rho_{\text {obsd }}=1.57 \mathrm{~g} \mathrm{~cm}^{-3}$. Two hexants of data were collected on an automated Nonius CAD-3 diffractometer with Mo K $\alpha$ radiation up to a $\sin \theta / \lambda$ limit of $0.48 \AA^{-1}$ and merged to give 758 nonzero reflections. The structure was solved by heavy atom methods and refined anisotropically to a final $R$ factor of $3.8 \%{ }^{4}$

The geometry of the molecule is shown in Figure 1. Selected bond lengths and bond angles are listed in Table I. Copies of the final atomic parameters are available. ${ }^{5}$
$\mathrm{Fe}_{1}$ is $\sigma$ bonded to $\mathrm{C}_{7}$ and $\mathrm{C}_{10}$ and forms part of the metallocyclic ring $\mathrm{Fe}_{1} \mathrm{C}_{7} \mathrm{C}_{8} \mathrm{C}_{9} \mathrm{C}_{10}$. $\mathrm{Fe}_{2}$, on the other hand, is $\pi$ bonded to the four carbon atoms of the metallocycle, much as in a butadiene complex. The $\mathrm{Fe}_{1}-\mathrm{Fe}_{2}$ distance of 2.462 (3) $\AA$ lies within the bonding range. The $\mathrm{Fe}_{2}(\mathrm{CO})_{6} \mathrm{C}_{4}$ portion of the molecule (i.e., the portion of the molecule without the eight methylene groups) closely resembles related "metallocycle + butadiene complex" linkages as found in $\mathrm{Fe}_{2}(\mathrm{CO})_{6}{ }^{-}$ $\left(\mathrm{CH}_{3} \mathrm{C} \equiv \mathrm{COH}\right)_{2}{ }^{6} \quad \mathrm{Fe}_{3}(\mathrm{CO})_{8}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C} \equiv \mathrm{CC}_{6} \mathrm{H}_{5}\right)_{2},{ }^{7} \quad \mathrm{Fe}_{2}-$
(4) Least-squares refinement was done using ucigls, a version o orfls (W. R. Busing and H. A. Levy) modified by R. J. Doedens and J. A. Ibers. All other major computations were performed using Crym, an amalgamated set of crystallographic programs developed by R. E. Marsh's group at the California Institute of Technology.

Figure 2. An alternative view of the structure of $\left(\mathrm{C}_{12} \mathrm{H}_{16}\right) \mathrm{Fe}_{2}(\mathrm{CO})_{6}$. The eight methylene groups have been left out for clarity. Note the close $\mathrm{Fe}_{1} \cdots \mathrm{C}_{6}$ interaction and the curious bending of the $\mathrm{Fe}_{2}-\mathrm{C}_{6}-\mathrm{O}_{6}$ angle. Also note that the $\mathrm{C}_{1}-\mathrm{Fe}_{1} \cdots \mathrm{C}_{6}$ angle is almost linear.

Table I. Selected Bond Distances and Angles in $\left(\mathrm{C}_{12} \mathrm{H}_{16}\right) \mathrm{Fe}_{2}(\mathrm{CO})_{6}$

| Bond Distances ( $\AA$ ) |  |  |  |
| :---: | :---: | :---: | :---: |
| $\mathrm{Fe}_{1}-\mathrm{Fe}_{2}$ | 2.462 (3) | $\mathrm{Fe}_{2}-\mathrm{C}_{6}$ | 1.753 (21) |
| $\mathrm{Fe}_{1}-\mathrm{C}_{1}$ | 1.724 (21) | $\mathrm{Fe}_{2}-\mathrm{C}_{7}$ | 2.087 (14) |
| $\mathrm{Fe}_{1}-\mathrm{C}_{2}$ | 1.787 (22) | $\mathrm{Fe}_{2}-\mathrm{C}_{8}$ | 2.172 (12) |
| $\mathrm{Fe}_{1}-\mathrm{C}_{3}$ | 1.740 (22) | $\mathrm{Fe}_{2}-\mathrm{C}_{9}$ | 2.189 (13) |
| $\mathrm{Fe}_{1} \cdots \mathrm{C}_{6}$ | 2.321 (19) | $\mathrm{Fe}_{2}-\mathrm{C}_{10}$ | 2.066 (12) |
| $\mathrm{Fe}_{1}-\mathrm{C}_{7}$ | 1.935 (13) | $\mathrm{C}_{7}-\mathrm{C}_{8}$ | 1.414 (19) |
| $\mathrm{Fe}_{1}-\mathrm{Cl}_{10}$ | 1.987 (14) | $\mathrm{C}_{8}-\mathrm{C}_{9}$ | 1.429 (21) |
| $\mathrm{Fe}_{2}-\mathrm{C}_{4}$ | 1.736 (25) | $\mathrm{C}_{9}-\mathrm{C}_{10}$ | 1.404 (17) |
| $\mathrm{Fe}_{2}-\mathrm{C}_{5}$ | 1.725 (25) |  |  |
| Bond Angles (in deg) |  |  |  |
| $\mathrm{C}_{1}-\mathrm{Fe}_{1}-\mathrm{Fe}_{2}$ | 129.0 (7) | $\mathrm{Fe}_{1}-\mathrm{Fe}_{2}-\mathrm{C}_{4}$ | 136.1 (8) |
| $\mathrm{C}_{1}-\mathrm{Fe}_{1} \cdots \mathrm{C}_{6}$ | 171.8 (9) | $\mathrm{Fe}_{1}-\mathrm{Fe}_{2}-\mathrm{C}_{5}$ | 127.6 (6) |
| $\mathrm{C}_{2}-\mathrm{Fe}_{1}-\mathrm{C}_{10}$ | 173.0 (7) | $\mathrm{Fe}_{1}-\mathrm{Fe}_{2}-\mathrm{C}_{6}$ | 64.3 (6) |
| $\mathrm{C}_{3}-\mathrm{Fe}_{1}-\mathrm{C}_{7}$ | 167.7 (9) | $\mathrm{Fe}_{2}-\mathrm{C}_{6} \cdots \mathrm{Fe}_{1}$ | 72.8 (7) |
| $\mathrm{Fe}_{1} \cdots \mathrm{C}_{6}-\mathrm{O}_{6}$ | 125.1 (26) | $\mathrm{Fe}_{2}-\mathrm{C}_{6}-\mathrm{O}_{6}$ | 161.9 (28) |
| $\mathrm{Fe}_{1}-\mathrm{C}_{7}-\mathrm{C}_{8}$ | 116.5 (10) | $\mathrm{C}_{7}-\mathrm{C}_{8}-\mathrm{C}_{9}$ | 114.4 (11) |
| $\mathrm{Fe}_{1}-\mathrm{C}_{10}-\mathrm{C}_{9}$ | 117.1 (11) | $\mathrm{C}_{8}-\mathrm{C}_{9}-\mathrm{C}_{10}$ | 110.9 (12) |

$(\mathrm{CO})_{4}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C} \equiv \mathrm{CC}_{6} \mathrm{H}_{4} \mathrm{C} \equiv \mathrm{CC}_{6} \mathrm{H}_{5}\right)_{2},{ }^{8} \quad$ and $\quad\left[\mathrm{Rh}_{2} \mathrm{Cl}_{2}-\right.$ $\left.(\mathrm{CO})\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{C} \equiv \mathrm{CC}_{2} \mathrm{H}_{5}\right)_{2}\right]_{2} \cdot 9$ A close interaction exists between $\mathrm{Fe}_{1}$ and $\mathrm{C}_{6}(2.32(2) \AA)$; this causes a bending of the $\mathrm{Fe}_{2}-\mathrm{C}_{6}-\mathrm{O}_{6}$ angle to 162 (3) ${ }^{\circ}$. This feature is shown most vividly in Figure 2. In fact, it looks very much as though it is $\mathrm{C}_{6}$ rather than $\mathrm{Fe}_{2}$ that fills the sixth octahedral coordination position around $\mathrm{Fe}_{1}$. The $\mathrm{Fe}_{1} \cdots \mathrm{C}_{6}$ interaction is almost strong enough to be considered bonding-this would make $\mathrm{C}_{6}-\mathrm{O}_{6}$, technically speaking, a highly asymmetrical bridging carbonyl group, a geometrical feature which has been observed in several other compounds. ${ }^{6.8,10}$ In $\mathrm{Fe}_{2}(\mathrm{CO})_{6}$ $\left(\mathrm{CH}_{3} \mathrm{C} \equiv \mathrm{COH}\right)_{2}$, for example, a close $\mathrm{Fe} \cdots \mathrm{C}$ interaction of $2.48 \AA$ is coupled to a bent $\mathrm{Fe}-\mathrm{C}-\mathrm{O}$ angle of $168^{\circ}, 6$ while in $\mathrm{Fe}_{2}(\mathrm{CO})_{4}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C} \equiv \mathrm{CC}_{6} \mathrm{H}_{4} \mathrm{C} \equiv \mathrm{CC}_{6} \mathrm{H}_{5}\right)_{2}$ the corresponding molecular parameters are 2.39 (2) $\AA$ and $166(2)^{\circ} .8$

(10) (a) D. B. W. Yawney and R. J. Doedens, Inorg. Chem., 11, 838 (1972); (b) M. R. Churchill and M. V. Veidis, J. Chem. Soc. A, 2170 (1971); (c) M. R. Churchill, J. Wormald, J. Knight, and M. J. Mays, J. Amer. Chem. Soc., 93, 3073 (1971).

One other noticeable feature of the molecular structure is the disorder of the methylene groups. This appears in Figure 1 as unusually elongated thermal ellipsoids for the eight methylene carbons, particularly the four central ones $\left(\mathrm{C}_{12}, \mathrm{C}_{13}, \mathrm{C}_{16}, \mathrm{C}_{17}\right)$. This effect is best explained in terms of a $1: 1$ statistical disorder involving a superposition of the two stable half-chair conformers Va and Vb (as in cyclohexene ${ }^{11}$ ) of each of

the six-membered rings. Attempts at resolving the disorder problem by using equally populated halfcarbon atoms in the least-squares refinement were not entirely successful.

The most remarkable feature of this structure determination is the unexpected ${ }^{12}$ finding that a gross skeletal rearrangement of the starting diyne (from a $12-\mathrm{mem}$ bered ring to a bicyclohexenyl-type framework) has occurred upon complexation. This reaction probably occurs via the formation of a metallocycle of type VI first, which then rearranges to the observed type VIII metallocycle. One can speculate about the possible

VI

VII

VIII
intermediacy of a cyclobutadiene-type species VII in the VI to VIII rearrangement process. The isolation ${ }^{1 b}$ of trace amounts of III from the reaction mixture indicates that, at the very least, the formation of cyclobutadiene complexes is possible in this system. While there is ample evidence for a VI-to-VII type process from previous studies on related systems, ${ }^{13}$ the VII-toVIII type conversion (which may very well involve participation by the second iron atom) is, as far as we know, unknown.

Irrespective of whether VII is a true intermediate or not, our result suggests that metallocyclic intermediates may play a prominent part in the mechanism of tung-sten-catalyzed alkyne disproportionation reactions ${ }^{14}$ (eq 1) and also suggests that the $\mathrm{Fe}(\mathrm{CO})_{5}$ system may

$$
\begin{equation*}
\mathrm{R}_{1} \mathrm{C} \equiv \mathrm{CR}_{1}+\mathrm{R}_{2} \mathrm{C} \equiv \mathrm{CR}_{2} \rightleftharpoons 2 \mathrm{R}_{1} \mathrm{C} \equiv \mathrm{CR}_{2} \tag{1}
\end{equation*}
$$

in fact be one where such processes might take place. We would like to point out that other metallocycles (saturated analogs of VIII) have been implicated as intermediates in olefin disproportionation ${ }^{15}$ and other skeletal rearrangement reactions. Very recently one such intermediate was isolated and structurally characterized. ${ }^{16}$

## Configurationally Isomeric Iminoxy Radicals. Intermediates in the Rearrangements of Nitrones to $O$-Alkyl Oximes ${ }^{1}$

Sir:
Previous investigations ${ }^{2,3}$ of the thermal rearrangement of $N$-benzhydryl- $\alpha, \alpha$-diphenylnitrone (1) to benzophenone $O$-benzhydryloxime (2) provide evidence for a homolytic cleavage to iminoxy and benzhydryl radicals with subsequent recombination at oxygen. ${ }^{4}$ We now report evidence which indicates that geometrically isomeric diaryliminoxy radicals ( $Z$ )-4 and ( $E$ )-4 undergo syn-anti isomerization five or six orders of magnitude faster than the corresponding oxime anions.

A study of the geometric course of the N to O rearrangements of syn-anti isomeric nitrones $((Z)-3$ and $(E)-3)$ offered an opportunity to estimate the rates of geometric isomerization of iminoxy radicals in the absence of such potential isomerization catalysts as acids and oxidizing agents. ${ }^{5}$

The minimum number of processes which were anticipated for these nitrone decompositions is shown in Scheme I. Retention of configuration in product formation would be expected in the case $\left[\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{2} \dot{\mathrm{C}} \mathrm{H}\right] k_{d}$ $\gg k_{3}$ or $k_{4}$. Retention would also be anticipated if the N to O rearrangement was concerted (i.e., via a quasi three-membered ring transition state). ${ }^{6}$ The two $O$ -
