initio calculations lead to $5 \pi$ states at $60^{\circ}$ with energies about 3 eV above the comparable states at $117^{\circ}$, the INDO calculations lead to $5 \pi$ states at $60^{\circ}$ with energies about 0 to 1 eV below the comparable states at $117^{\circ}$.

## III. Discussion

The most grievious fault of INDO apparent in our calculations on ozone is the strong bias toward closed geometries, ${ }^{50}$ even when unfavorable electron interactions should make small bond angles strictly repulsive, e.g., for the ${ }^{1} \mathrm{~A}_{1}(5 \pi),{ }^{3} \mathrm{~A}_{2}(5 \pi),{ }^{1} \mathrm{~B}_{1}(5 \pi),{ }^{3} \mathrm{~B}_{1}(5 \pi)$, and ${ }^{3} \mathrm{~B}_{2}(6 \pi)$ states. Similar problems with INDO have been found previously. ${ }^{51}$ It appears as if INDO does not properly represent the repulsion involved
(50) Subsequent to submission of this paper, A. K. Q. Siu and E. F. Hayes, Chem. Phys. Lett., 21, 573 (1973), published semiempirical HF calculations on the open ( $1^{1} \mathrm{~A}_{1}$ ) and ring ( $2^{1} \mathrm{~A}_{1}$ ) states of ozone, in which they reported that the CNDO/2, INDO, and MINDO approximations all favored the ring state by 5 to 10 eV over the open state, in agreement with our results. Siu and Hayes also reported ab initio Hartree-Fock calculations, leading to the ring state about 0.36 eV above the open ground state. However, as shown earlier from $a b$ initio GVB and CI calculations, HF wave functions (which exclude electron correlations) are biased in favor of the ring state by 1 eV or more, so that the ab initio relative energy ( 0.39 eV ) of the ring and open states obtained by Siu and Hayes is much smaller than the real spacing between these states. Extensive DZ-CI calculations ${ }^{9 c}$ indicate that the ring state is 1.57 eV above the open ground state.
(51) M. Froimowitz and P. J. Gans, J. Amer. Chem. Soc., 94, 8020 (1972); see also T. Morton, Ph.D. Thesis, California Institute of Technology, 1972.
when triplet-coupled electrons are forced into close proximity. In addition it appears that INDO gives rise to $\pi$ bonds that are far too strong. The latter explanation would be consistent with the short bond lengths observed for ${ }^{1} \mathrm{~A}_{1}(4 \pi)$ and the large transition energies observed for the $4 \pi \rightarrow 5 \pi$ and $4 \pi \rightarrow 6 \pi$ transitions (at the calculated equilibrium geometry). Consequently, the use of INDO for calculating equilibrium geometries as in conformational studies or reaction pathways is very risky, even if correlation effects are included.

Our calculations show that INDO treats the electron correlations involved in the GVB(1) wave function fairly well, so that using such correlated wave functions will cure some of the gross errors encountered when INDO is used with the HF method. However, introduction of CI need not improve the energy spectrum obtained with INDO and, in fact, may make it worse. (See, for example, the reordering of the $5 \pi$ and $6 \pi$ states after CI.) Nevertheless, despite certain significant errors in describing the overall energy spectrum, INDO does reproduce many of the energy separations properly, e.g., the singlet-triplet splittings of states arising from the same configurations. This indicates to us that it may be possible to develop a method on the order of INDO in complexity that would yield reliable results (comparable at least to $a b$ initio MBS calculations). Work is in progress along these lines.

# Symmetry Adapted Functions and Normalized Spherical Harmonic (NSH) Hamiltonians for the Point Groups $O_{h}, T_{d}, D_{4 b}, D_{2 d}, C_{4 v}, D_{2 b}, C_{2 v}$ 

J. C. Hempel, J. C. Donini, B. R. Hollebone, and A. B. P. Lever*<br>Contribution from the Department of Chemistry, York University, Downsview, Ontario, Canada. Received September 13, 1973

#### Abstract

A general method is introduced for the projection of normalized spherical harmonic (NSH) Hamiltonians. Subgroups of $O_{h}$ which subduce $C_{2 v}$ are specifically considered, and $\mathrm{d}^{n}$ basis functions symmetry adapted to the various groups are derived. The advantages of a symmetry-adapted basis are emphasized in the interpretation of absorption spectra of three nickel(II) systems characterized by $C_{2 v}$ effective symmetry. Symmetry-adapted representations of $H_{G}$ for $G=O_{h}, T_{d}, D_{4 h}, C_{4 v}, D_{2 d}, D_{2 h}$, and $C_{2 v}$ are tabulated for the d ${ }^{1}$ (and d ${ }^{9}$ ) configuration, the spin triplet states of the $d^{2}$ (and $d^{8}$ ) configuration, and the spin quartet states of the $d^{3}$ (and $d^{7}$ ) configuration.

Although the absorption spectra of many transition metal systems have been reproduced using a ligand field Hamiltonian and $l^{n}$ basis set, ${ }^{1-3}$ calculations assuming $D_{2 d}, D_{2 h}$, or $C_{2 v}$ symmetry are not common. ${ }^{4-7}$ Hamiltonians for $D_{2 h}$ or $C_{2 v}$ symmetry and a $\mathrm{d}^{n}$ basis

[^0]set incorporate a maximum of five empirical parameters (excluding interelectronic repulsion parameters), in contrast to a maximum of three such parameters for symmetries with a fourfold axis. Spectra are therefore often interpreted assuming the symmetry of a higher point group for calculation purposes. Only in certain cases can the assumption be justified. ${ }^{8}$ We present a method for the projection of normalized spherical harmonic (NSH) Hamiltonians which is applicable to all point group symmetries and offers not only the possibility of straightforward calculations for noncubic as well as cubic symmetries but also the possibility of
(8) J. S. Griffith, Mol. Phys., 8, 217 (1964).
standardizing correlation procedures. The empirical parameters which arise are independent of the coordinate system used for calculations and may be compared with parameters from the crystal field ${ }^{9}$ or angular overlap model ${ }^{10}$ to determine restrictions on parameter values. The approach parallels recent developments by Schäffer ${ }^{10}$ and Ellzey. ${ }^{11}$

As illustrated in the interpretation of spectra of three nickel(II) systems characterized by $C_{2 v}$ effective symmetry, a representation of $H$ on a basis symmetry adapted to the point group defines relationships between empirical parameters and experimental observables thus minimizing the difficulty of the parameter fitting procedure. Symmetry-adapted representations also minimize computation and provide a point group quantum number for identification of calculated energy states. A derivation of $\mathrm{d}^{n}$ basis functions symmetry adapted to point group chains ${ }^{12}$ terminating with $C_{2}$ v is included as are normalized spherical harmonic Hamiltonians for all point groups in the chains. Symmetryadapted representations for $\mathrm{d}^{n}$ configurations with $n=1,2$, and 3 and $G=O_{h}, T_{d}, D_{4 h}, C_{4 v}, D_{2 d}, D_{2 h}$, and $C_{2 r}$ are tabulated (Appendix).

## Theory

A transition metal complex with $n$ valence electrons is represented by an $n$-electron Hamiltonian of the form

$$
\begin{equation*}
H=H^{\circ}+H_{G} \tag{1}
\end{equation*}
$$

where $H^{\circ}$ is the free ion Hamiltonian and

$$
\begin{equation*}
\left[H^{\circ}, G_{a}\right]=0 ; \quad G_{a} \in[R(3)]^{n} \tag{2}
\end{equation*}
$$

[ $R(3)]^{n}$ is the $n$th rank inner direct product of the rotation grnup in three dimensions, $R(3)$. Integers $L=$ $0,1,2, \ldots$ characterize irreducible representations of [ $R(3)]^{n}$ and are quantum numbers for $H^{\circ} . \quad H_{G}$ represents the ligand field, where

$$
\begin{equation*}
\left[H_{G}, G_{a}\right]=0 ; \quad G_{a} \in[G]^{n} \tag{3}
\end{equation*}
$$

and $[G]^{n}$ is the $n$th rank inner direct product of a point group $G$. Irreducible representations of $[G]^{n}$, denoted $Q(G)$, are quantum numbers for $H$. For the octahedral group, $Q(0)=A_{1}, A_{2}, E, T_{1}$, and $T_{2}$.

The potential $H_{G}$ is expanded in terms of tensor operators, ${ }^{10}$ where

$$
\begin{gather*}
H_{G}=\sum_{i=1}^{n} P_{i} \\
P_{i}=\sum_{L} \sum_{M} B_{M}^{L} C_{M}^{L} \tag{4}
\end{gather*}
$$

and the $C_{M}{ }^{L}$ tensors with $M=L, L-1, \ldots,-L$ are a basis for an irreducible representation of $R(3)$. Any vanishing of $B_{M}{ }^{L}$ coefficients is determined not only by the symmetry of the environment of the transition metal but also by the choice of coordinate system. ${ }^{10,13}$ Non-

vanishing $B_{M}{ }^{L}$ coefficients are directly related to ligand field parameters to be fitted from experiment. We choose to expand $P$ in terms of linear combinations of tensor operators which transform according to an irreducible representation of $G$. The linear combinations

$$
\begin{equation*}
|\tau Q R|_{G}^{L}=\sum_{M} C_{M}^{L}\langle L M \mid \tau Q R\rangle_{G} \tag{5}
\end{equation*}
$$

are orthonormal. A degeneracy index $R$ identifies components of the irreducible representation $Q(G)$ and $\tau$ distinguishes $Q(G)$ if more than one $Q$ of the same kind is subduced by $L$. Symmetry adaptation coefficients $\langle L M \mid \tau Q R\rangle_{G}$ for the octahedral group have been tabulated by Griffith. ${ }^{14}$

After expansion

$$
\begin{equation*}
P=\sum_{L} \sum_{\tau} A^{L ; \tau}\left|\tau \mathrm{A}_{1} \mathrm{a}_{1}\right|_{G}^{L} \tag{6}
\end{equation*}
$$

since only those linear combinations of tensor operators which transform as $\mathrm{A}_{1}$ (or $\mathrm{A}_{1 \mathrm{~g}}$ ) can have nonvanishing coefficients. ${ }^{11,15,16}$ The coefficients $A^{L ; \tau}$ serve as empirical parameters to be evaluated from experiment. ${ }^{17}$ Their magnitudes are independent of coordinate system.

In addition $H$ is a spin free Hamiltonian ${ }^{18}$ where

$$
\begin{equation*}
\left[H, P_{a}{ }^{\mathrm{SF}}\right]=0 ; P_{a}{ }^{\mathrm{SF}} \in S_{n}{ }^{\mathrm{SF}} \tag{7}
\end{equation*}
$$

and $S_{n}{ }^{\mathrm{sF}}$ is the group of permutations on the spatial coordinates of the $n$ electrons. The partitions [ $\lambda$ ] of $S_{n}{ }^{\mathrm{sF}}$ are exact quantum numbers for $H$ and yield the multiplicity quantum number $\mathfrak{F}=2 S+1$.

Basis Functions. A representation of $H$ in the $5^{n}$ dimensional spin free vector space $V^{\mathrm{SF}}\left(\mathrm{d}^{n}\right)$ is a function of the ligand field parameters $A^{L ; \tau}$ and the Racah parameters $A, B$, and $C$. Although eigenvalues and eigenkets can be obtained from a representation of $H$ on the $\left|\mathrm{d}^{n: M} L M\right\rangle$ basis of $V^{\mathrm{SF}}\left(\mathrm{d}^{n}\right),{ }^{19-22}$ a representation of $H$ on a basis symmetry adapted to [ $G]^{n}$ has certain advantages. ${ }^{1,11,17,23}$ Namely, the representation is block diagonal since

$$
\begin{align*}
& \left\langle\mathrm{d}^{n} ;{ }^{\mathfrak{M r}} L ; \tau^{\mathfrak{M r}} \mathfrak{Q} R\right| H\left|\mathrm{~d}^{n} ; \mathfrak{M r}^{\prime} L^{\prime} ; \tau^{\prime \text { Mr }} \mathfrak{Q}^{\prime} R^{\prime}\right\rangle= \\
& \delta\left(\mathfrak{N}, \mathfrak{T}^{\prime}\right) \delta\left(\mathbb{Q}, Q^{\prime}\right) \delta\left(R, R^{\prime}\right)  \tag{8}\\
& \left\langle\mathrm{d}^{n} ;{ }^{\Re} L ; \tau^{\Re \pi} Q R\right| H\left|\mathrm{~d}^{n} ;{ }^{\mathfrak{M r}} L^{\prime} ; \tau^{\prime \mathfrak{M}} Q R\right\rangle
\end{align*}
$$

and each block is identified by an irreducible representation of the point group of interest. Symmetry adaptation coefficients suitable for the projection of $\mid \mathrm{d}^{n}$; $\left.{ }^{{ }^{M}} L ; \tau^{\mathfrak{M}} Q R\right\rangle$ basis functions for $O_{h}$ or $D_{4 h}$ symmetry are readily available. ${ }^{14}$ Making use of the previously tabulated functions we project bases for $\mathrm{d}^{n}$ configura-

& O_{h} \longrightarrow T_{d} \longrightarrow D_{2 d} \longrightarrow C_{2 v} \tag{13}
\end{align*}
$$

A chain is an ordering of groups in which each group contains the elements of every group lower in the chain and is a proper subgroup of every group higher in the chain. In these examples $O_{h}$ is the head and $C_{2 v}$ the tail of the chain. Many noncubic molecules of interest to transition metal chemists fall into one of these chains. The threefold groups are not discussed here but can be treated in an exactly analogous manner.

Each group, a member of chains $9-13$, can be denoted $G(S)$ where $S$ represents the set of octahedral operations retained by $G$. For example, three sets of octahedral operations can be retained to generate $C_{2 v}$.

$$
\begin{aligned}
\mathrm{I} & =\left\{E, C_{4}{ }^{2}(z), \sigma_{h}(x z), \sigma_{h}(y z)\right\} \\
\mathrm{II} & =\left\{E, C_{4}{ }^{2}(z), \sigma_{d}(x y), \sigma_{d}(\bar{x} y)\right\} \\
\mathrm{III} & =\left\{E, C_{2}{ }^{\prime}(x y), \sigma_{h}(x y), \sigma_{d}(x y)\right\}
\end{aligned}
$$

Each $C_{2 v}(S)$, where $S=$ I, II, or III, retains a $C_{4}{ }^{2}$ or $C_{2}{ }^{\prime}$ operation from the $3 C_{2}$ or $6 C_{2}^{\prime}$ classes of $O_{h}$, two mutually perpendicular reflection planes whose line of intersection is the twofold axis, and the identity operation. Symmetry operations of $O_{h}$ are defined with respect to the symmetry axes of an octahedron which pass through the ligands of a six coordinate $O_{h}$ system. A right-handed coordinate system is assumed. When the basis of an irreducible representation ${ }^{26}$ of $O_{h}$, denoted $Q\left(O_{h}\right)$, is symmetry adapted to chain 10 , for example, it is also a basis for one or more irreducible representations of $D_{4 h}, D_{2 d}$, and $C_{2 r}$. The matrices $D\left(G_{a}\right) \in \mathbb{Q}\left(O_{h}\right)$ for the operations of the octahedral group retained by $G=D_{4 h}, D_{2 d}$, or $C_{2 v}$ have a block diagonal form with each irreducible representation of $G$ subduced corresponding to one such block. Basis functions and correlation tables for the gerade irreducible representations of $O_{h}$ symmetry adapted to chains 9,10 , or 11 terminating with $C_{2_{r}}(\mathrm{I})$ are given in Table I. These bases are also symmetry adapted to chain 12. Correlation tables are included in Tables II and III for a basis symmetry adapted to chain 9 terminating with $C_{2 v}$ (II), chain 11 terminating with $C_{2 v}$ (II) or $C_{2 v}$ (III), and chain 13 terminating with $C_{2_{v}}$ (II). Also included in Tables I-III are definitions of $S$ for $D_{2 d}(S)$, $S=\mathrm{I}$ and II, and $D_{2 h}(S), S=\mathrm{I}$ and II.

Symmetry properties of basis elements are summarized as functions of $x, y$, and $z$. The $D\left(G_{a}\right) \in$ $Q\left(O_{h}\right)$ for $\mathbb{Q}=\mathrm{A}_{1 \mathrm{~g}}, \mathrm{~A}_{2 \mathrm{~g}}, \mathrm{E}_{\mathrm{g}}, \mathrm{T}_{1 \mathrm{~g}}$, or $\mathrm{T}_{2 \mathrm{~g}}$ can therefore be reconstructed since by definition ${ }^{26}$

$$
\begin{equation*}
G_{a} \phi_{i}=\sum_{j=1}^{N} D_{j i}\left(G_{a}\right) \phi_{j} \tag{14}
\end{equation*}
$$

where $B_{N}=\left\{\phi_{i} ; i=1, N\right\}$ is the basis of $Q\left(O_{h}\right)$ and

Table III. Basis Functions and Correlation Table for the Gerade Irreducible Representations of $O_{h}$ Relevant to Chain 13

$D_{j i}\left(G_{a}\right)$ is an element of the matrix $D\left(G_{a}\right)$. Tables I-III were obtained by bringing $Q\left(O_{h}\right)$ for a previously reported basis ${ }^{27}$ to the appropriate block diagonal form and relating any similarity transformations required to basis transformations. ${ }^{26}$

Linear combinations of tensor components symmetry adapted to $O_{h}$ and characterized by the symmetry of the basis functions given in Table I have been reported previously by Griffith ${ }^{14}$ for $L=0,1, \ldots, 6$. The symmetry adaptation coefficients tabulated yield either gerade or ungerade functions since the inversion symmetry of the projected function reflects the inversion symmetry of its tensor components. One-electron tensor operators are $g$ if $L$ is even and $u$ if $L$ is odd. Components of a $\left|\mathrm{d}^{n ; 9 \pi} L M\right\rangle$ basis are always $g$.

Given $L=2$ functions tabulated by Griffith and Table I, we deduce

$$
\begin{array}{r}
\left|\mathrm{E}_{\mathrm{g}} \theta ; \mathrm{A}_{1 \mathrm{~g}} ; \mathrm{A}_{1} ; \mathrm{A}_{1}\right\rangle=|20\rangle \\
\left|\mathrm{E}_{\mathrm{g} \epsilon} ; \quad \mathrm{B}_{1 \mathrm{~g}} ; \quad \mathrm{B}_{2} ; \quad \mathrm{A}_{1}\right\rangle=\frac{1}{\sqrt{2}}\{|22\rangle+|2 \overline{2}\rangle\} \\
\left|\mathrm{T}_{2 \mathrm{~g}}(y z) ; \mathrm{E}_{\mathrm{g}}(y z) ; \mathrm{E}(y z) ; \mathrm{B}_{2}\right\rangle=i / \sqrt{2}\{|2 \overline{\mathrm{I}}\rangle+|21\rangle\}  \tag{15}\\
\left|\mathrm{T}_{2 \mathrm{~g}}(x z) ; \mathrm{E}_{\mathrm{g}}(x z) ; \mathrm{E}(x z) ; \mathrm{B}_{1}\right\rangle=1 / \sqrt{2}\{|2 \overline{\mathrm{l}}\rangle-|21\rangle\} \\
\left|\mathrm{T}_{2 \mathrm{~g}}(x y) ; \quad \mathrm{B}_{2 \mathrm{~g}} ; \quad \mathrm{B}_{1} ; \quad \mathrm{A}_{2}\right\rangle=-i / \sqrt{2}\{|22\rangle-|2 \overline{2}\rangle\}
\end{array}
$$

where the functions are identified by an irreducible representation and degeneracy index for the groups $O_{h}, D_{4 n}, D_{2 d}(\mathrm{I})$, and $C_{2 r}(\mathrm{I})$, respectively. Symmetryadapted functions for a chain terminating with ${ }^{\circ} C_{2 v}$ (II) are obtained as linear combinations of the tabulated functions. For $L=2$

$$
\begin{gather*}
\left|\mathrm{E}_{\mathrm{g}} \theta ; \mathrm{A}_{1 \mathrm{~g}} ; \quad \mathrm{A}_{8} ; \mathrm{A}_{1}\right\rangle=|20\rangle \\
\left|\mathrm{E}_{\mathrm{q}} ; \quad \mathrm{B}_{1 \mathrm{~g}} ; \mathrm{B}_{1 g} ; \mathrm{A}_{2}\right\rangle=1 / \sqrt{2}\{|22\rangle+|2 \overline{2}\rangle\} \\
\left|\mathrm{T}_{2 g} \tau_{2} ; \mathrm{E}_{\mathrm{g}} \tau_{2} ; \mathrm{B}_{2 g} ; \mathrm{B}_{1}\right\rangle=1 / 2\{a|2 \overline{1}\rangle+b|21\rangle\}  \tag{16}\\
\left|\mathrm{T}_{2 g} \tau_{2} ; \quad \mathrm{E}_{\mathrm{g}} \tau_{2} ; \quad \mathrm{B}_{3 \mathrm{~g}} ; \mathrm{B}_{2}\right\rangle=1 / 2\{b|2 \overline{\mathrm{I}}\rangle+a|21\rangle\} \\
\left|\mathrm{T}_{2 g}(x y) ; \mathrm{B}_{2 \mathrm{~g}} ; \mathrm{A}_{8} ; \quad \mathrm{A}_{1}\right\rangle=i / \sqrt{2}\{|22\rangle-|2 \overline{2}\rangle\}
\end{gather*}
$$

where $a=i+1$ and $b=i-1$, and functions are identified by irreducible representations of $O_{h}, D_{4 h}, D_{\mathrm{s}_{h}}$ (II), and $C_{2 v}$ (II), respectively. Therefore, given the information in Tables I-III and previously tabulated ${ }^{14}$ symmetry adaptation coefficients for $O_{h},\left|\mathrm{~d}^{n},{ }^{, \pi} L ; \tau^{M \pi} \mathbb{Q} R\right\rangle$ basis functions and ligand field operators are readily generated for the point group symmetries of interest.

Hamiltonians. Those $\mathrm{d}^{n}$ compounds characterized
by the point group symmetry of a member of the chains terminating with $C_{2 v}$ require ligand field Hamiltonians of the following form

$$
\begin{equation*}
H_{G}=V \tag{17}
\end{equation*}
$$

when $G=O_{h}$ and $T_{a}$

$$
\begin{equation*}
H_{\theta}=V+V^{\prime} \tag{18}
\end{equation*}
$$

when $G=D_{4 h}, C_{4 v}, D_{2 d}(\mathrm{I})$, and $D_{2 d}(\mathrm{II})$

$$
\begin{equation*}
H_{G}=V+V^{\prime}+V^{\prime \prime} \tag{19}
\end{equation*}
$$

when $G=D_{2 n}(\mathrm{I})$ and $C_{2 v}(\mathrm{I})$

$$
\begin{equation*}
H_{G}=V+V^{\prime}+V^{\prime \prime \prime} \tag{20}
\end{equation*}
$$

when $G=D_{2 h}(\mathrm{II}), C_{2 v}(\mathrm{II})$, and $C_{2 v}(\mathrm{III})$
where

$$
\begin{gather*}
V=D Q\left|\mathrm{~A}_{1 \mathrm{~g}}\right| o_{o}{ }^{4}  \tag{21}\\
V^{\prime}=D S\left|\mathrm{E}_{g} \theta\right|_{o_{h}}{ }^{2}+D T\left|\mathrm{E}_{g} \theta\right|_{o_{h}{ }^{4}}  \tag{22}\\
V^{\prime \prime}=D U\left|\mathrm{E}_{\mathrm{g}} \epsilon\right|_{o_{k}}{ }^{2}+D V\left|\mathrm{E}_{\mathrm{g}} \epsilon\right|_{o_{h}}{ }^{4}  \tag{23}\\
V^{\prime \prime \prime}=D M\left|\mathrm{~T}_{2 \mathrm{~g}}(x y)\right|_{o_{h}}{ }^{2}+D N\left|\mathrm{~T}_{2 \mathrm{~g}}(x y)\right|_{o_{h}{ }^{4}} \tag{24}
\end{gather*}
$$

$O_{n}$ quantum numbers identify linear combinations of tensor operators which transform as $A_{1}$ (or $\mathrm{A}_{1 \mathrm{~g}}$ ) of $G$ (see Table I). $A^{L ; \tau}$ coefficients (eq 6 ) are called $D Q$, $D S, D T, D U$, and $D V$ by analogy to previously defined ${ }^{28}$ parameters $D q, D s$, and $D t$. Although $\mathrm{A}_{2 \mathrm{~g}}$ of $O_{h}$ subduces $\mathrm{A}_{1}$ of $D_{2 h}(\mathrm{I})$ and $C_{2 v}(\mathrm{I})$, no functions of this form appear in eq 19 since Hamiltonians for $\mathrm{d}^{n}$ configurations can be projected from even tensors of rank four or less, ${ }^{2,3}$ and irreducible representations of $R(3)$ with $L=0,2,4$ do not subduce $\mathrm{A}_{2 g}$ of $O_{h} .{ }^{3,27}$ Symmetry adapted expansions are given in Table IV. ${ }^{14}$

Table IV. Operator Expansions Symmetry Adapted ${ }^{a}$ to $O_{h}$

```

\(\left.\mathrm{E}_{\mathrm{g}} \theta\right|_{O_{\mathrm{h}}{ }^{2}=C_{0}{ }^{2}, ~}\)
\(\left.\mathrm{E}_{\mathrm{g}} \epsilon\right|_{o_{h}}{ }^{2}=(1 / \sqrt{2})\left(C_{2}{ }^{2}+C_{-2}{ }^{2}\right)\)
\(\left.\mathrm{T}_{2}(x y)\right|_{o_{n}}{ }^{2}=(-i / \sqrt{2})\left(C_{2}{ }^{2}-C_{-2}{ }^{2}\right)\)
\(\mathrm{A}_{\mathrm{tg}} \mid O_{h}^{4}=(7 / 12)^{1 / 2} C_{0}{ }^{4}+(5 / 24)^{1 / 2}\left(C_{4}^{4}+C_{-4}{ }^{4}\right)\)
\(\mathrm{E}_{8} \theta| |_{h^{4}}=(-5 / 12)^{1 / 2} C_{0}{ }^{4}+(7 / 24)^{1 / 2}\left(C_{4}{ }^{4}+C_{-4}{ }^{4}\right)\)
\(\mathrm{E}_{\mathrm{g}} \in{ }_{O_{h}}{ }^{4}=(1 / \sqrt{2})\left(C_{2}{ }^{4}+C_{-2}{ }^{4}\right)\)
\(\left.\mathrm{T}_{2}(x y)\right|_{O_{h}}{ }^{4}=(-i / \sqrt{2})\left(C_{2}{ }^{4}-C_{-2^{4}}\right)\)
```

## ${ }^{a}$ Reference 14.

The $A_{1 g}$ component arising from $L=0$ contributes equally to the energy of each state of a $\mathrm{d}^{n}$ configuration and is not included in the ligand field operator. As indicated, the Hamiltonians for $D_{4 h}, C_{4 v}$, and $D_{2 d}$ are indistinguishable. Similarly, the Hamiltonian for $D_{2 h}(\mathrm{I})$ is indistinguishable from that for $C_{2 v}(\mathrm{I})$ (see Table I). Nonzero matrix elements of $V, V^{\prime}, V^{\prime \prime}$, and $V^{\prime \prime \prime}$ on a d orbital basis symmetry adapted to the appropriate chain, eq 15 or 16 , are given in Table V . The matrix elements for $V$ and $V^{\prime}$ relate $D S, D T$, and $D Q$ parameters to the previously defined ${ }^{28}$ parameters $D s, D t$, and $D q$ where

$$
\begin{gather*}
D Q=6(21)^{1 / 2} D q-7 / 2(21)^{1 / 2} D t  \tag{25}\\
D T=7 / 2(15)^{1 / 2} D t  \tag{26}\\
D S=-7 D s \tag{27}
\end{gather*}
$$

${ }^{a}$ Defined in Tables I and II. ${ }^{b}$ Defined by eq 20 and 24.

Note that in the octahedral limit $D Q=6(21)^{1 / 2} D q$. Note also that for a Hamiltonian of the form $V+V^{\prime}$ the center of gravity rule holds within the $\mathrm{e}_{\mathrm{g}}$ and $\mathrm{t}_{2 \mathrm{~g}}$ levels of a $\mathrm{d}^{1}$ system for $D S$ and $D T$ energy components, an observation which is independent of the $d$ basis used for calculations. See Appendix.

## Six-Coordinate Systems

Ligand substitutions and angular distortions leading to a first coordination sphere characterized by $C_{20}$ symmetry are summarized in Table VI and Figure 1.

Table VI. Mixed Ligand Six-Coordinate Systems Which Can Exhibit $C_{2 v}$ Symmetry

|  | Highest available <br> point group symmetry ${ }^{a}$ | Possible $C_{2 v}$ <br> distortion <br> patterns |  |
| :--- | :--- | :--- | :--- |
| $\mathbf{M A}_{6}$ | $O_{h}$ | I, II, III |  |
| $\mathbf{M A}_{4} \mathbf{X Y}$ | Trans | $C_{4 v}$ | I, II |
| $\mathbf{M A}_{4} \mathbf{B}_{2}$ | Trans | $D_{4 h}$ | I, II, III |
|  | Cis | $C_{2 v}$ | III |
| $\mathbf{M A}_{2} \mathbf{B}_{2} \mathbf{X Y}$ | Trans | $C_{2 v}$ | I |

${ }^{a}$ Corresponds to the symmetry of an octahedral angular configuration. ${ }^{b}$ As defined by Figure 1 .

Although mixed ligand systems may exhibit angular distortions, the highest symmetry available to each corresponds to the symmetry of an octahedral angular configuration. For example, the limiting symmetry for trans $-\mathrm{MA}_{4} \mathrm{~B}_{2}$ is $D_{4 k}$ while that for cis- $\mathrm{MA}_{4} \mathrm{~B}_{2}$ is $C_{20}$ (Table VI). Any distortion of the octahedral angular configuration lifts the $D_{4 k}$ symmetry of the trans

Definitions of the angular configuration for (1) $O_{h}$ (axes pass through ligand positions; $\alpha_{1}=\alpha_{2}=90^{\circ} ; \theta_{i}=90^{\circ} ; \psi_{1}=$ $\left.\psi_{2}=90^{\circ}\right) ;(2) C_{2 v}(\mathrm{I})\left(\mathrm{I}=\left\{E, C_{2}(z), \sigma_{h}(x z), \sigma_{h}(y z)\right\} ;\right.$ ligands 5 and 6 lie on the $z$ axis; $\alpha_{1}=\alpha_{2}=90^{\circ} ; \theta_{1}=\theta_{3}, \theta_{2}=\theta_{4}$, and $0^{\circ}<$ $\theta_{1}$ and $\left.\theta_{2}<180^{\circ} ; \psi_{1}=\psi_{2}=90^{\circ}\right)$; (3) $C_{2 v}(\mathrm{II})(\mathrm{II})=\left\{E, C_{2}(z)\right.$, $\left.\sigma_{d}(x y), \sigma_{d}(\bar{x} y)\right\} ;$ ligands 5 and 6 lie on the $z$ axis; $0^{\circ}<\alpha_{1}=\alpha_{2} \leq 90^{\circ}$, $\theta_{i}=\theta$ for $0^{\circ}<\theta<180^{\circ} ; \psi_{1}=\psi_{2}=90^{\circ}$ ); (4) $C_{2 v}($ III $)$ (III $=\{E$, $\left.C_{2}{ }^{\prime}(x y), \sigma_{h}(x y), \sigma_{d}(x y)\right\}$; ligands 1,2,3, and 4 lie in the $x y$ plane; $\left.0^{\circ}<\alpha_{1}, \alpha_{2}, \leq 180^{\circ} ; \theta_{i}=90^{\circ} ; 0^{\circ}<\psi_{1}=\psi_{2} \leq 90^{\circ}\right)$.
system, while the cis system retains $C_{20}$ symmetry for a $C_{2_{v}}$ (III) angular configuration, as defined by Figure 1.

Parameters suitable for empirical ligand field calculations on a $\mathrm{d}^{n}$ basis are specified in eq 17-24. The number of parameters required for each symmetry is dictated by the symmetry and the choice to restrict consideration to states arising from a $\mathrm{d}^{n}$ configuration. That is to say

$$
\begin{equation*}
N_{p}=\sum_{L=2,4} f^{L ; \mathrm{A}_{1}} \tag{28}
\end{equation*}
$$

where $f^{L ; A_{1}}$ is the number of times $L$ subduces $\mathrm{A}_{1}$ (or $\mathrm{A}_{1 \mathrm{~g}}$ ) of the point group of interest. However, assuming ligand additivity and an average electrostatic effect for

${ }^{a}$ The $\left|\mathrm{d}^{2} ;{ }^{3} F ; 1 Q\left(C_{2 v}(\mathrm{I})\right)\right\rangle$ for $Q=\mathrm{A}_{2}, \mathrm{~B}_{1}, \mathrm{~B}_{2}$ arise from $\mathrm{G}\left(O_{h}\right)=\mathrm{T}_{1 \mathrm{~g}}$. ${ }^{b}$ The nonzero matrix elements for the ${ }^{3} \mathrm{~B}_{2}$ states are derived from the matrix elements tabulated for the ${ }^{3} \mathrm{~B}_{1}$ states using the negative of the starred $\left(^{*}\right)$ multipliers and the other multipliers as tabulated.
different ligands, assumptions implicit in most applications of empirical crystal field theory, ${ }^{8-10,29}$ certain systems require fewer than $N_{p}$ parameters.

By relating empirical crystal field parameters ${ }^{9}$ for the six-coordinate molecules in Table VI to the empirical $A^{L_{i \tau}}$ parameters, one finds that

$$
\begin{align*}
& D U=\left(R_{1}+R_{3}\right) \sin ^{2} \theta_{1}-\left(R_{2}+R_{4}\right) \sin ^{2} \theta_{2} \\
& D M=\left(R_{1}+R_{4}\right) \sin \left(90-\alpha_{1}\right) \sin ^{2} \theta+  \tag{29}\\
& \left(R_{2}+R_{3}\right) \sin \left(90-\alpha_{2}\right) \sin ^{2} \theta
\end{align*}
$$

where $R_{i}$ is an empirical radial parameter for ligand $i$, and the angles $\theta_{i}, \alpha_{1}$, and $\alpha_{2}$ are defined in Figure 1. Therefore, $D M$ (and $D N$ ) always go to zero when a $C_{2 v}$ (II) or $C_{2 r}$ (III) system (Table VI) retains an octahedral angular configuration $\left(\theta=\alpha=90^{\circ}\right.$ ) and ligand additivity is assumed. Similarly, $D U$ (and $D V$ ) go to zero when a trans- $\mathrm{MA}_{4} \mathrm{XY} \quad C_{2 t}(\mathrm{I})$ system is characterized by $\theta_{1}=90-\delta$ and $\theta_{2}=90+\delta$. In such a case $H_{C_{2 v}}$ has exactly the same form as $H_{G}$ where $G=$ $D_{4 h}, C_{4 t}$, and $D_{2 a}$. These compounds may therefore be described with a Hamiltonian of higher symmetry than $C_{20}$ and reflect a property previously termed intermediate symmetry by Griffith. ${ }^{8}$ The equatorial (meridional) configuration of a $\mathrm{MA}_{3} \mathrm{~B}_{3}$ system ( $C_{2 r}$ (I) symmetry) can also display a type of intermediate symmetry. When the system retains an octahedral angular configuration, $D S$ and $D T$ go to zero and the system can be described with the parameters $D U, D Q$, and DV

To demonstrate the utility of this procedure, it is applied in the analysis of three nickel complexes whose polarized crystal spectra have been published. It is a feature of the spectra of noncubic complexes of the twofold groups that the selection rules are in general not so well obeyed as those for representative examples from the fourfold groups. For this reason the assignments cannot be considered so secure; application of the tensor Hamiltonian technique will serve to provide an additional means of verifying assignments through correlation of parameter values.

Octahedral nickel(II) systems ( $\mathrm{d}^{8}$ ) have an orbitally nondegenerate ${ }^{3} \mathrm{~A}_{2 g}$ ground state. Three relatively intense bands are observed in the absorption spectrum of an octahedral complex and may be assigned to the ${ }^{3} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F}) \rightarrow{ }^{3} \mathrm{~T}_{2 \mathrm{~g}}(\mathrm{~F}),{ }^{3} \mathrm{~T}_{1 g}(\mathrm{~F})$, and ${ }^{3} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{P})$ transitions of

[^1]increasing energy, respectively. In a complex of $C_{20}$ symmetry, the orbital degeneracy of the excited triplet states is lifted and there are nine possible spin-allowed transitions. The $x, y$, and $z$ components of the electric dipole vector transform as $\mathrm{B}_{1}, \mathrm{~B}_{2}$, and $\mathrm{A}_{1}$, respectively, for $C_{2 v}$ symmetry where $x, y$, and $z$ refer to the symmetry axes for $C_{20}{ }^{30}$
$D_{2 h}(\mathbf{I})$ and $C_{2 t}(\mathbf{I})$. Polarized single crystal electronic spectra of bis(diethylenetriamine)nickel(II) chloride monohydrate have been reported by Fereday and Hathaway. ${ }^{31}$ The tridentate ligand diethylenetriamine (den) coordinates equatorially. ${ }^{32}$ Secondary nitrogens, which lie trans to one another, define a $C_{2}$ axis and the $\mathrm{N}-\mathrm{Ni}-\mathrm{N}$ angle made by the primary nitrogens within a den ring is $\sim 162^{\circ}$. Although the nickel(II) cation as a whole does not have a $C_{2}$ axis, polarized absorption spectra indicate an effective symmetry higher than the $C_{1}$ crystallographic site symmetry. Three absorption bands are observed in each of three crystal orientations with the electric field vector essentially along $x, y$, and $z$ symmetry axes of $C_{2 v}$ or $D_{2 h}$. ${ }^{30}$ An assumption of $D_{2 h}$ symmetry, suggested by Fereday and Hathaway, ${ }^{31}$ predicts ${ }^{33}$ the observation of nine triplet-triplet bands. $H_{D 24(\mathrm{I})}$ is indistinguishable in form from $H_{C_{22}(\mathrm{I})}$ (eq 19) and the $x$, $y$, and $z$ components of the electric dipole vector transform as $b_{3 u}, b_{2 u}$, and $b_{1 u}$ for $D_{2 h}$ symmetry. ${ }^{30}$

The representation of $H(e q 1)$ for $D_{2 n}(\mathrm{I})$ symmetry on a basis symmetry adapted to $C_{20}$ (I) is given in Table VII for the triplet states of a $d^{2}$ configuration. See Appendix. Since the trace of a matrix is invariant under diagonalization, various combinations of the experimentally observed transition energies are directly related to traces of blocks of the representation and can be used to establish relationships between $B, D Q, D S$, $D T, D U$, and $D V$. For example

$$
\begin{equation*}
\frac{2}{7} \sqrt{3} D U+\frac{4}{21} \sqrt{5} D V=\operatorname{Tr}\left({ }^{3} \mathrm{~B}_{2 \mathrm{~g}}\right)-\operatorname{Tr}\left({ }^{3} \mathrm{~B}_{3 \mathrm{~g}}\right) \tag{30}
\end{equation*}
$$

where $\operatorname{Tr}\left({ }^{3} \mathscr{Q}\left(D_{2 n}\right)\right)$ refers to the sum of the energies of transitions from the ground state to excited triplet

[^2]states characterized by the quantum number $\mathfrak{a}\left(D_{2 h}\right)$. Similarly
\[

$$
\begin{array}{r}
\frac{3}{7} D S+\frac{6}{21} \sqrt{\frac{5}{3}} D T=\frac{1}{2} \operatorname{Tr}\left({ }^{3} \mathrm{~B}_{2 \mathrm{~g}}\right)+ \\
\frac{1}{2} \operatorname{Tr}\left({ }^{3} \mathrm{~B}_{3 \mathrm{~g}}\right)-\operatorname{Tr}\left({ }^{3} \mathrm{~B}_{1 \mathrm{~g}}\right) \\
15 B-\frac{20}{3 \sqrt{21}} D Q=\frac{1}{3} \operatorname{Tr}\left({ }^{3} \mathrm{~B}_{1 \mathrm{~g}}\right)+\frac{1}{3} \operatorname{Tr}\left({ }^{3} \mathrm{~B}_{2 \mathrm{~g}}\right)+ \\
\frac{1}{3} \operatorname{Tr}\left({ }^{3} \mathrm{~B}_{3 \mathrm{~g}}\right)-3 \operatorname{Tr}\left({ }^{3} \mathrm{~A}_{\mathrm{g}}\right) \tag{32}
\end{array}
$$
\]

Therefore, when nine triplet-triplet transitions are observed, there are three independent variables to be fitted from experiment: $B$ (or $D Q$ ), $D U$ (or $D V$ ), and $D S$ (or $D T$ ). Transitions calculated with $B=$ $780, D S=-435, D U=-100, D Q=-32,215$, $D T=370, D V=350 \mathrm{~cm}^{-1}$, and a d ${ }^{2}$ basis are compared with experimental values for $\left[\mathrm{Ni}(\mathrm{den})_{2}\right]^{2+}$ in Table VIII. The parameters reported exactly repro-

duce the ${ }^{3} \mathrm{~A}_{\mathrm{g}} \rightarrow{ }^{3} \mathrm{~B}_{1 \mathrm{~g}}$ transition energies as well as the trace (or sum) of the ${ }^{3} \mathrm{~A}_{\mathrm{g}} \rightarrow{ }^{3} \mathrm{~B}_{3 \mathrm{~g}}$ transition energies and the trace of the ${ }^{3} \mathrm{~A}_{\mathrm{g}} \rightarrow{ }^{3} \mathrm{~B}_{2 \mathrm{~g}}$ transition energies. Although the first excited triplet state is calculated to have the same point group quantum number as the highest excited triplet state for all parameter sets which reproduce the traces, this is not observed experimentally.

An interpretation of the polarized single crystal spectra of $\left[\mathrm{Ni}(\text { den })_{2}\right]^{2+}$ assuming $D_{2 h}$ symmetry implies that the angular distortion revealed by the X-ray structure study ${ }^{32}$ does not determine the effective symmetry of the system. Assumption of $C_{20}(\mathrm{I})$ symmetry is consistent with the angular distortion and implies only that the primary nitrogens of the den ligand are distinct, which may reflect the small bond length difference obtained in the X-ray structure determination and/or a small deviation in the $\mathrm{N}-\mathrm{Ni}-\mathrm{N}$ angles within the two den rings.
$C_{2 v}$ (III). Polarized single crystal absorption spectra for bis(DL-histidinato)nickel(II) monohydrate have been reported by Meredith and Palmer. ${ }^{6}$ The tridentate histidine molecules bond through three inequivalent functional groups and coordinate facially. ${ }^{34}$ Oxygens
(34) K. A. Fraser and M. M. Harding, J. Chem. Soc. A, 415 (1967).
from the carboxy group and nitrogens from the $\alpha$-amino group of each ligand lie in a plane with an $\mathrm{O}-\mathrm{Ni}-\mathrm{O}$ angle of $100.3^{\circ}$ and an $\mathrm{O}-\mathrm{Ni}-\mathrm{N}_{\mathrm{A}}$ angle of $79.7^{\circ}$. The two remaining bonds, imidazole nitrogen-nickel bonds, deviate from colinearity by $2.4^{\circ}$. The site symmetry of the nickel atoms is $C_{2} .{ }^{34}$

Eight of nine possible spin-allowed triplet-triplet transitions are observed in $x, y$, and $z$ polarizations ${ }^{30}$ with some of the transitions forbidden (not observed) in each polarization. Meredith and Palmer assumed $C_{20}$ (III) symmetry, the symmetry of the first coordination sphere of the nickel ion, in an interpretation of the spectra. A full calculation for $C_{2 v}$ symmetry was carried out within the $d^{2}$ configuration using an empirical Hamiltonian in the form of eq 4. The coordinate system used by Meredith and Palmer to define the tensor operators lies with its $z$ axis bisecting the $\mathrm{O}-\mathrm{Ni}-\mathrm{O}$ angle and its $x$ axis bisecting the $\mathrm{N}_{\mathrm{A}}-\mathrm{Ni}-\mathrm{O}$ angle. For this choice of coordinate system nonzero $B_{M}{ }^{L}$ coefficients multiply only those $C_{M}{ }^{L}$ operators with $L=2, M=0$, $\pm 2$ and $L=4, M=0, \pm 2, \pm 4 .^{10.13}$ It should be noted, however, that the coordinate systems with $x, y$, and $z$ labels permuted correspond to Hamiltonians of the same form. The coordinate choice is fixed only by the assignment of the point group symmetry quantum number associated with each calculated energy state. That is to say, the form of the projection operators ${ }^{35}$ or symmetry adapted basis functions used to determine $Q(G)$ reflects the coordinate system choice. Therefore, a fitting procedure which reproduces energy level splittings by adjustment of $B_{M}{ }^{L}$ parameters for $L=2$, $M=0, \pm 2$ and $L=4, M=0, \pm 2, \pm 4$ can be expected to find a number of equivalent fits. $\quad B_{M}{ }^{L}$ coefficients reported by Meredith and Palmer convert to $D Q=-31504, D S=-1955, D T=2155, D M=$ 3409 , and $D N=-5149 \mathrm{~cm}^{-1}$. These $A^{L ; \tau}$ parameters, defined by eq 23 , reproduce the energy level splittings and assignments given in Table IX (with $B=783$ $\mathrm{cm}^{-1}$ ) in any coordinate system.

${ }^{a}$ The nonzero matrix elements for the ${ }^{3} \mathbf{B}_{2}$ states are derived from the matrix elements tabulated for the ${ }^{3} \mathbf{B}_{1}$ (or ${ }^{3} \mathbf{A}_{2}$ ) states using the negative of the starred $\left(^{*}\right)$ multipliers and the other multipliers as tabulated. ${ }^{b}$ The $\left|\mathrm{d}^{2},{ }^{3} F ; 1 a\left(C_{2 v}(I I)\right)\right\rangle$ for $a=B_{1}, A_{2}$, and $B_{2}$ arise from $Q\left(O_{h}\right)=$ $\mathrm{T}_{\mathrm{Ig}}$.
for the spin triplet states. See Appendix. The following relationships are deduced from Table X

$$
\begin{array}{r}
\frac{2}{7}(3)^{1 / 2} D M+\frac{4}{21}(5)^{1 / 2} D N=\operatorname{Tr}\left({ }^{3} \mathrm{~B}_{2}\right)-\operatorname{Tr}\left({ }^{3} \mathrm{~A}_{2}\right) \\
-\frac{2}{7} D S+\frac{8}{7}\left(\frac{5}{3}\right)^{1 / 2} D T+15 B=\operatorname{Tr}\left({ }^{3} \mathrm{~B}_{1}\right)-3 \operatorname{Tr}\left({ }^{3} \mathrm{~A}_{1}\right) \\
\frac{3}{7} D S-\frac{1}{21} D T-\frac{5}{3 \sqrt{21}} D Q= \\
\frac{1}{2} \operatorname{Tr}\left({ }^{3} \mathrm{~A}_{2}\right)+\frac{1}{2} \operatorname{Tr}\left({ }^{3} \mathrm{~B}_{2}\right)-\operatorname{Tr}\left({ }^{3} \mathrm{~B}_{1}\right) \tag{35}
\end{array}
$$

where $\operatorname{Tr}{ }^{3} a^{3}\left(C_{2_{0}}(\right.$ III $\left.)\right)$ refers to the sum of the energies of transitions from the ground state to excited triplet states characterized by $\mathfrak{A}\left(C_{20}(\right.$ III $\left.)\right)$. When nine spinallowed triplet-triplet transitions are observed, the energies of the triplet states can be specified with four independent variables, for example, $B, D M$ (or $D N$ ), $D S($ or $D T)$, and $D Q$. Transitions calculated with $B=$ $820, D M=3000, D N=-3955, D S=-3000, D T$ $=1859$, and $D Q=-31069 \mathrm{~cm}^{-1}$ are compared with experimental values for $\left[\mathrm{Ni}(\mathrm{DL}-\mathrm{his})_{2}\right]$ in Table IX. This fit, which retains the $C_{2 v}$ assignments made by Meredith and Palmer, exactly reproduces the ${ }^{3} \mathrm{~B}_{1} \rightarrow{ }^{3} \mathrm{~B}_{1}$ and ${ }^{3} \mathrm{~B}_{1}$ $\rightarrow{ }^{3} \mathrm{~A}_{1}$ transition energies as well as the trace of the ${ }^{3} \mathrm{~B}_{1} \rightarrow{ }^{3} \mathrm{~A}_{2}$ transitions. Since one ${ }^{3} \mathrm{~B}_{1} \rightarrow{ }^{3} \mathrm{~B}_{2}$ transition is not observed experimentally, five variables were allowed to vary independently in the fitting procedure. The fit compares favorably with that of Meredith and Palmer, in which six parameters were varied independently.

A scissoring distortion in the $x z$ plane ${ }^{30}$ can be measured in units of $2 \beta$, where $\angle \mathrm{O}-\mathrm{Ni}-\mathrm{O}=90^{\circ}-2 \beta$ and $\angle \mathrm{O}-\mathrm{Ni}-\mathrm{N}_{\mathrm{A}}=90^{\circ}+2 \beta$. Relating $A^{L_{i \tau}}$ parameters to empirical crystal field parameters one finds that

$$
\begin{align*}
& {[\cos (4 \beta)] D N }= \\
& \quad[-\sin (2 \beta)]\{\sqrt{5 / 21} D Q+\sqrt{1 / 3} D T\} \tag{36}
\end{align*}
$$

where $-2 \beta \simeq 18^{\circ}$ for Meredith and Palmer's fit ${ }^{6}$ of the experimental spectrum and $-2 \beta \simeq 14^{\circ}$ for the fit obtained with five independent variables. From the X-ray structure determination ${ }^{34}$ one would expect $-2 \beta \simeq 10.3^{\circ}$. The $A^{L ; r}$ parameters obtained for
$\mathrm{Ni}(\mathrm{DL}-\mathrm{his})_{2}$ therefore not only adequately reproduce the absorption spectrum but can be used to predict a distortion observed experimentally. Although electric dipole selection rules for $C_{20}$ symmetry are not strictly obeyed, all predicted transitions are observed.

## Four-Coordinate Systems

Many $\mathrm{ML}_{4}$ systems exhibit one of the two limiting symmetries available to a four-coordinate system: $D_{4 h}$ (square planar) or $T_{a}$ (tetrahedral). ${ }^{7}$ Equations 29 relate empirical crystal field parameters for fourcoordinate systems to parameters $D U$ and $D M$ defined by the chains incorporating $D_{4 b}$. With the assumption of ligand additivity, $D M$ (and $D N$ ) go to zero for the $D_{4 b}$ angular configuration of cis-MA ${ }_{2} \mathrm{~B}_{2}\left(\theta=\alpha=90^{\circ}\right)$ and the system exhibits intermediate symmetry. 8,29 Similarly, one finds that the $D_{4 t}$ angular configuration of trans- $\mathrm{MA}_{2} \mathrm{~B}_{2}$ can be described with $D Q, D U, D V$, $D S$, and $D T=1 / 2(5 / 7)^{1 / 2} D Q$ and the $D_{4 h}$ angular configuration of $\mathrm{MA}_{4}$ with $D S, D Q$, and $D T=1 / 2(5 / 7)^{1 / 2} D Q$.

Projections of ligand position vectors are defined to lie on $45^{\circ}$ diagonals in the $x y$ plane for $T_{a}$ symmetry in contrast to the $D_{4 h}$ system, where symmetry axes pass through ligand positions. For this reason a $C_{20}(\mathrm{II})$ distortion of the $T_{a}$ configuration is equivalent to a $C_{20^{-}}$ (I) distortion of the $D_{4 h}$ configuration. Parameters which indicate the distortion from $T_{a}$ symmetry arise in the first approach while parameters which indicate the distortion from $D_{4 n}$ symmetry arise in the second. $D M$ for chain 13 , incorporating $T_{d}$, is given by

$$
\begin{equation*}
D M=2 R_{\mathrm{A}} \sin ^{2} \theta_{1}-2 R_{\mathrm{B}} \sin ^{2} \theta_{2} \tag{37}
\end{equation*}
$$

where $R_{\mathrm{A}}$ and $R_{\mathrm{B}}$ are the empirical radial parameters for ligands in positions 1 and 3 and 2 and 4, respectively. Ligand positions are indexed by the spherical coordinates $\left(\theta_{i}, \phi_{i}\right)$ with $\phi_{1}=45^{\circ}, \phi_{i+1}=\phi_{i}+90^{\circ}$, and $\theta_{1}$ $=\theta_{3}, \theta_{2}=\theta_{4}$. The $T_{a}$ angular configuration of $\mathrm{MA}_{2} \mathrm{~B}_{2}$, characterized by $C_{2_{0}}(\mathrm{II})$, can be described with $D M$, $D N$, and $D Q$ when an assumption of ligand additivity holds.

We have restricted consideration to $\mathrm{MA}_{4}$ and $\mathrm{MA}_{2} \mathrm{~B}_{2}$ systems, systems which can exhibit $C_{20}$ symmetry and which require Hamiltonians and basis functions symmetry adapted to chains $9,10,11$, or 13 . The theory and techniques outlined are applied to a four-coordi-

${ }^{a}$ References 4 and 36. ${ }^{b}$ Allowed polarization. ${ }^{c} B=835$, $C=2,700, D S=2,200, D T=-4,982$, and $D Q=20,000 \mathrm{~cm}^{-1}$. ${ }^{d}$ Reference 4: $B=790, C=3160, D S=132, D T=-1350$, and $D Q=9947 \mathrm{~cm}^{-1}$.

Gerloch and Slade ${ }^{4}$ report an extensive oriented single crystal magnetic susceptibility study of $\mathrm{Ni}(i-\operatorname{Pr}-$ $\mathrm{sal}_{2}$ for $T \geq 80^{\circ} \mathrm{K}$ in which they conclude that the effective symmetry of the system is $D_{2 d}$. Magnetic susceptibilities were calculated using an empirical crystal field Hamiltonian incorporating spin-orbit and Zeeman terms with $\lambda \simeq-100 \mathrm{~cm}^{-1}$ and $k=0.4$. Converting empirical crystal field parameters used in the magnetic susceptibility fitting procedure to $A^{L ; \tau}$ parameters, one obtains $D S=132, D T=-1350$, and $D Q=9947 \mathrm{~cm}^{-1}$. Triplet-triplet transition energies calculated with these parameters (and $B=790$ $\mathrm{cm}^{-1}$ ) are compared with experimental values in Table XI. It should be noted that the bands at $\sim 17,500$ and

${ }^{a}$ For energy levels calculated with a $\mathrm{d}^{2}$ basis.
nate nickel system characterized by an approximately tetrahedral configuration. A tetrahedral nickel(II) system is expected to exhibit three spin-allowed absorption bands, assigned as ${ }^{3} \mathrm{~T}_{1}(\mathrm{~F}) \rightarrow{ }^{3} \mathrm{~T}_{2}(\mathrm{~F}),{ }^{3} \mathrm{~A}_{2}(\mathrm{~F})$, and ${ }^{3} \mathrm{~T}_{1}(\mathrm{P})$. In $C_{20}$ symmetry the orbital degeneracy of the states is removed and there exists the possibility of observing nine triplet-triplet transitions. However, if the distortion from $T_{a}$ symmetry is small, the two levels arising from the ground state lie at very low energies.
$C_{20}$ (II). Polarized single crystal spectra for bis( $N$-isopropylsalicylaldiminato)nickel(II) have been reported by Basu and Belford ${ }^{36}$ and by Gerloch and Slade. ${ }^{4}$ The conformation of the first coordination sphere corresponds very nearly to the $C_{2_{0}}$ (II) distortion of a tetrahedral configuration. ${ }^{37}$ Planar isopropylsalicylaldimine ( $i-\mathrm{Pr}-\mathrm{sal}$ ) ligands bond through an imine nitrogen and a hydroxy oxygen with an $\mathrm{O}(1)-\mathrm{Ni}-\mathrm{O}(2)$ angle of $\sim 125^{\circ}$ and a $\mathrm{N}(1)-\mathrm{Ni}-\mathrm{N}(2)$ angle of $\sim 121^{\circ}$. The ligand planes intersect at an angle of $82^{\circ}$. The system contains discrete molecules characterized by a triplet ground state. ${ }^{37,38}$

Six bands are observed in the absorption spectrum of $\mathrm{Ni}(i-\mathrm{Pr}-\mathrm{sal})_{2}$ with the electric field vector parallel to $b$ and to $c$ crystal axes. ${ }^{4,36}$ One band ( $\sim 11,000$ $\mathrm{cm}^{-1}$ ) is weak and sharp, characteristic of a spin-forbidden band. Another ( $\sim 22,400 \mathrm{~cm}^{-1}$ ) is relatively very intense. The four remaining bands (at $\sim 6000$, $14,280,17,500$, and $19,000 \mathrm{~cm}^{-1}$ ) are of comparable intensity, characteristic of spin-allowed d-d bands. ${ }^{39}$

[^3]$19,000 \mathrm{~cm}^{-1}$ are disregarded in the interpretation of data proposed by Gerloch and Slade. Triplet-triplet transitions calculated with $B=835, D S=2200, D T$ $=-4982$, and $D Q=20,000 \mathrm{~cm}^{-1}$ are also given in Table XI. These parameters reproduce all observed transitions and preliminary calculations ${ }^{40}$ indicate that the parameters will reproduce the susceptibility data for $T \geq 80^{\circ} \mathrm{K}$ with $\lambda=140 \mathrm{~cm}^{-1}$ and $k \simeq 0.58$. The assumption of $D_{2 d}$ symmetry requires that the imine nitrogens and hydroxy oxygens be indistinguishable for symmetry purposes. A full polarization study of the absorption spectrum has not been done due to the unfavorable placement of nickel centers in the single crystal. ${ }^{37} \mathrm{Ni}(i-\mathrm{Pr} \text {-sal })_{2}$ could be characterized by a small splitting in the ${ }^{3} \mathrm{~A}_{2} \rightarrow{ }^{3} \mathrm{E}$ bands. In such a case the assumption of $C_{2 \sigma}$ symmetry predicts the four observed triplet-triplet bands. One of the bands is forbidden in $D_{2 d}$ symmetry (see Table XI). The low-lying spin-forbidden transition observed experimentally is essentially independent of crystal field strength and a $C$ value consistent with its observation is included in the footnote to Table XI for each interpretation of the ab sorption spectrum.

## Discussion

$A^{L_{i \tau}}$ parameters for three nickel(II) systems characterized by a $C_{20}$ effective symmetry are compared with parameters for other ${ }^{41,42}$ six-coordinate and four-coordinate nickel systems in Table XII. As indicated, the relative magnitudes of $D Q$ parameters for the sixcoordinate species reflect an increase in ligand field

[^4]"strength" for ligands which coordinate through nitrogen over that of an oxygen ligand in MgO. This observation tends to support the proposed interpretation of the $\mathrm{Ni}(i-\mathrm{Pr}-\mathrm{sal})_{2}$ spectrum which indicates an increase in ligand "strength," as measured by $D Q$, over that of the oxygen ligand in the tetrahedral ZnO matrix. The magnitudes of parameters $D S$ and $D T$ for the various systems, as well as $D M$ and $D N$ or $D U$ and $D V$, appear to reflect ligand substitution more sensitively than angular distortion. For example, $D M$ for a sixcoordinate $C_{2_{v}}(\mathrm{II})$ molecule is found to be much larger in absolute magnitude than DU for a $C_{2 v}(\mathrm{I})$ molecule. $D M$ is predicted to correspond to a sum and $D U$ to a difference of empirical radial parameters (eq 29).

If it is assumed that the potential due to the ligands is the sum of a potential due to each ligand and thatsimilar ligands are indistinguishable, certain deductions can be made concerning the symmetry of the various systems. For example, since $D S$ and $D T$ are nonzero for $\mathrm{Ni}(i \text { - } \mathrm{Pr} \text {-sal })_{2}$, the system is not characterized by a $T_{a}$ angular configuration and since $D M$ and $D N$ are nonzero for $\mathrm{Ni}(\mathrm{DL}-\mathrm{his})_{2}$, the system is not characterized by an $O_{h}$ angular configuration. These deductions do correlate with X-ray structure determinations. ${ }^{34,37}$ Further, the magnitude of a distortion in the first coordination sphere of $\mathrm{Ni}(\mathrm{DL}-\mathrm{his})_{2}$ can be deduced from $A^{L ; \tau}$ parameters $D Q, D T$, and $D N$ using a relation applicable to all six-coordinate systems charterized by $C_{2 v}(\mathrm{III})$ symmetry.

The nine triplet-triplet transitions of a nickel(II) system can be described with three independent parameters for $C_{2 v}(\mathrm{I})$ symmetry and with four independent parameters for $C_{2 v}$ (II) or $C_{2 p}$ (III) symmetry. Nine triplet-triplet transitions observed for $\mathrm{Ni}(\text { den })_{2}{ }^{2+}$ were fitted with three independent parameters ( $B, D S$, and $D U$ ), while the eight triplet-triplet transitions observed for $\mathrm{Ni}(\mathrm{DL}-\mathrm{his})_{2}$ were fitted with five independent parameters ( $B, D Q, D S, D T$, and $D M$ ). The four triplettriplet bands observed for $\mathrm{Ni}(i-\mathrm{Pr}-\mathrm{sal})_{2}$ were fitted with $B, D Q, D S$, and $D T$ (with $D M=D N=0$ ). For each of these systems, all triplet-triplet transitions predicted assuming $C_{20}$ symmetry are observed. Results of this study imply that the angular configuration of the first coordination sphere determines the effective symmetry of the system and that predictions based on an assumption of ligand additivity hold.

## Summary and Conclusion

The utility of normalized spherical harmonic Hamiltonians may be summarized as follows.
(i) Their adoption would provide a standard and systematic procedure for generating ligand field Hamiltonians in the noncubic point groups.
(ii) The scalar parameters generated with these NSH Hamiltonians are truly spherical and are therefore independent of coordinate axis choice. We have chosen in this article to expand all the tensor components along the same axes, i.e., a right-hand coordinate system quantized along the $C_{4}(z)$ octahedral axis, irrespective of the symmetry axes of the molecule concerned. In the threefold groups the same choice may be made but it may be computationally more favorable to utilize a set quantized along $C_{3}(x y z)\left(O_{h}\right)$. In either event the magnitudes of the scalar parameters obtained will be the same.
(iii) Clearly within a group of molecules belonging to the same point group, the variation of a given parameter, such as $D S$, as a function of the ligand or metal, may be compared and contrasted. It may also be useful to include, within this comparison, complexes of other stereochemistries whose point groups lie within the same subduction chain and whose Hamiltonians contain the same tensor component. In this way a systematic body of knowledge concerning the noncubic point groups can be amassed. Series of $D S$ or $D T$ paralleling the spectrochemical series of $D q$ could be generated. These would differ from the spectrochemical series in that the latter, for a given metal, is a function of only one ligand, while the former would be at least two dimensional being a function normally of at least two ligands. -For this reason, a melding of this tensor technique with the orbital angular overlap model will probably prove beneficial. ${ }^{10}$

This model provides an alternative to that based on the Gerloch and Slade ${ }^{43} C_{\mathrm{p}}$ parameter.

## Appendix

Tabulated Symmetry-Adapted Representations. Table V contains the nonzero matrix elements of a representation of $H$, eq 1 , for $G=O_{h}, T_{a}, D_{4 h}, D_{2 h}, D_{2 d}$, and $C_{2 v}$ on d ${ }^{1}$ bases symmetry adapted to $C_{2 v}(\mathrm{I}), C_{2 v}(\mathrm{II})$, and $C_{20}$ (III). To determine which matrix elements are required for the point group of interest refer to eq 17-24 to determine the form of $H_{G}$. Tables VII and X contain the nonzero matrix elements of $H$ for the spin triplet states of a d ${ }^{2}$ basis symmetry adapted to $C_{2}{ }_{v}(\mathrm{I})$ and $C_{2 v}$ (III), respectively. Tables VII and X also apply to the spin quartet states of a $\mathrm{d}^{7}$ basis. The representation of $H_{G}$ for $\mathrm{d}^{10-n}$ is in each case the negative of the representation for $\mathrm{d}^{n}$. The representation of $H^{\circ}$ does not change sign.
