and the 1,4 distance in 4 being less than in benzene. The effect is greater for the normal MINDO/3 calculations than for those with CI, as one would expect since the energies calculated for biradical species without CI are too large. 17 The geometry thus tends to approximate more closely to that of an equivalent nonradical structure (e.g., 4 instead of 2).

We also studied the energies of singlet 2 and 3 as a function of the distance between the "radical" centers. In the case of 2 only one minimum was found (Figure 1d, e, but with 3 there were two minima, one corresponding to 3 (Figure 1g, h, and the other to 5. Thus 3 or 5 is predicted to exist in two isomeric forms with different C₁C₄ distances. The second isomer is also predicted to be a distorted benzene (Figure 1j) with a very long transannular bond (1.667 Å) and little variation of bond lengths round the ring. The calculated $\Delta H_{\rm f}$ (152.8 kcal/mol) is much higher than that for 3 from which it is separated only by a low barrier (4.6 kcal/mol). In the transition state the C₁C₄ distance is 1.85 Å.

All calculations^{8,10} agree in predicting the singlet form of 1 to be the more stable. Those reported here differ, however, from previous ones8 in predicting 2 to have a singlet ground state. Since this is true both with and without CI, the prediction seems very strong. The opposite conclusion reached in the earlier calculation could then well be due to use of an unrealistic geometry for the singlet.

In the case of 3 the calculations are more ambiguous, those without CI predicting the ground state to be a triplet and those with CI a singlet. It seems likely that the ground state is in fact a singlet but with a small singlet-triplet separation. The ab initio calculations⁸ could well have led to the opposite conclusion through use of an incorrect geometry.

The most striking prediction from our calculations is that singlet 2 should be at least comparable in stability with singlet 1 (cf. Hess and Schaad¹⁸). This suggests that more consideration should be given to reaction mechanisms involving m-benzynes (e.g., 2) as intermediates.

A Kinetic Study of the Fate of a Covalent Intermediate of the Type Proposed to be Involved in Flavin Catalysis

A non-free-radical1 (dark) flavin oxo-reduction reaction not involving hydrogen transfer^{2,3} from substrate to

(3) S. Shinkai and T. C. Bruice, J. Amer. Chem. Soc., 95, 7526 (1973).

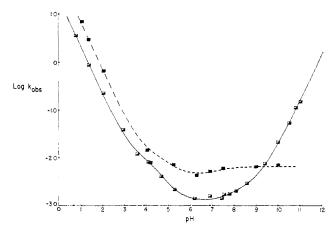

Figure 1. Log k_{obsd} vs. pH rate profile for solvolysis of 4a-InH —) and 4a-InMe (----): Solvent H₂O (aerobic), 30°, $\mu = 0.2$. Rate constants in min⁻¹. The E-2 elimination for 4a-InH may be seen in the slope of +1.

flavin would require the formation of a covalent intermediate. Based on chemical intuition 4 and photoreduction⁵ studies the site of covalent adduct formation has been suggested to be the 4a- and 5-positions, I and II,

respectively. A 5-carbinolamine adduct has been suggested as an intermediate in the reaction of nitroethane anion with oxidized deuterated amino acid oxidase, but this same adduct has been shown not to be an intermediate in the reduction of formaldehyde and ethyl pyruvate by reduced flavin. 1,3 No direct chemical evidence exists which establishes a 4a-adduct as an intermediate in a flavin catalyzed reaction though addition of SO₃²⁻ to the 4a-position has been established for one isoalloxazine.7

In aqueous solution (30°, $\mu = 0.2$ with KCl), the solvolysis of 4a-InH and 4a-InMe yields dihydroflavin (FH₂) under anaerobic conditions and oxidized flavin (F_{ox}) under aerobic conditions.⁸ The pH-log k_{obsd}

The mechanisms of Scheme I provide eq 3 and 4 which

Scheme I

$$4a-In(H,Me)H^{+} \xrightarrow{\stackrel{K_{a1}}{+H^{+}}} 4a-In(H,Me) \xrightarrow{\stackrel{k_{10}}{k_{-10}}} 5-In(H,Me)H \xrightarrow{\stackrel{K_{a2}}{+H^{+}}} + H^{+}$$

$$\downarrow k_{1} \atop k_{2}[H_{9}O^{+}] \qquad \downarrow k_{3}[OH^{-}] \qquad \downarrow k_{5}[OH^{-}] \qquad \downarrow k_{5}[OH^{-}]$$

$$\downarrow k_{1} \atop k_{2}[H_{9}O^{+}] \qquad \downarrow k_{5}[OH^{-}] \qquad \downarrow k_{5}[OH^{-}]$$

are kinetically identical with the empirical expressions of eq 1 and 2, respectively $(k_1 \text{ and } k_4 \text{ and } k_7 \text{ and } k_8 \text{ and }$ represent kinetically identical paths). In the derivation of eq 3 and 4, steady state has been assumed for 5-In-

$$k_{\text{obsd}} = \frac{(k_1 + k_2 a_{\text{H}}) a_{\text{H}}}{k_{\text{a}_1} + a_{\text{H}}} + \frac{K_{\text{a}_1}}{K_{\text{a}_1} + a_{\text{H}}} \left[k_3 + \frac{k_5 K_{\text{w}}}{a_{\text{H}}} + \frac{k_{10} (k_6 a_{\text{H}} + k_7 K_{\text{w}} + k_8 K_{\text{a}_2} + k_9 K_{\text{a}_2} K_{\text{w}} / a_{\text{H}})}{K_{\text{a}_1} (k_{-10} + k_8 + k_9 K_{\text{w}} / a_{\text{H}}) + a_{\text{H}} (k_{-10} + k_6) + k_7 K_{\text{w}}} \right]$$
(3)
$$k_{\text{obsd}} = \frac{a_{\text{H}} (k_1 + k_2 a_{\text{H}})}{K_{\text{a}_1} + a_{\text{H}}} + \frac{K_{\text{a}_1}}{K_{\text{a}_1} + a_{\text{H}}} \times \left[k_3 + \frac{k_{10} (k_6 a_{\text{H}} + k_8 K_{\text{a}_2})}{k_{-10} (K_{\text{a}_2} + a_{\text{H}}) + k_6 a_{\text{H}} + k_8 K_{\text{a}_2}} \right]$$
(4)

(H,Me)H and 5-In(H,Me) intermediates and the OH catalyzed paths through k_5 , k_7 , and k_9 are not allowed for 4a-InMe (see eq 1 vs. 2).9 The values of $pK_{a_1} = 4.4$ and 4.9 are comparable to the p K_a of protonation on the 5-position obtained for 5-adducts (3.4)10 and alkyl-substituted anilines $(4.3-5.5)^{11}$ while p K_{a2} 's = 8.1 are in the range of 7-8 previously reported for dissociation of the H-N₁ proton of N₅-substituted 1,5-dihydroflavins.⁵ The isomerization of the 4a- to 5-adducts of Scheme I has precedence in observations from Hemmerich's laboratory. 12,13 In Scheme I this reaction is spontaneous with equilibrium constants of $K_2 = 5$ -In(H,-

(9) The constants derived from the pH-log $k_{0\text{bad}}$ profiles to fit eq 3 and 4 follow: for 4a-InH $k_1=0$ when $k_4=276$ M^{-1} min⁻¹, $k_1=1\times 10^{-2}$ min⁻¹ when $k_4=0$, $k_2=22$ M^{-1} min⁻¹, $k_3=7.9\times 10^{-4}$ min⁻¹, $k_5=112$ M^{-1} min⁻¹, $k_6=1.15\times 10^{-4}$ min⁻¹, $k_7=0$ when $k_8=5.74\times 10^{-4}$ min⁻¹, $k_7=310$ M^{-1} min⁻¹ when $k_8=0$, $k_9=25$ M^{-1} min⁻¹, $k_{10}=3.5\times 10^{-3}$ min⁻¹, $k_{-10}=8.0\times 10^{-4}$ min⁻¹, $pK_{a_1}=4.4$, $pK_{a_2}=8.1$; for 4a-InMe $k_1=0$ when $k_4=954$ M^{-1} min⁻¹, $k_1=1.2\times 10^{-2}$ min⁻¹ when $k_4=0$, $k_2=71$ M^{-1} min⁻¹, $k_3=1.5\times 10^{-3}$ min⁻¹, $k_6=8.0\times 10^{-4}$ min⁻¹, $k_8=9.7\times 10^{-3}$ min⁻¹, $k_{10}=5.5\times 10^{-3}$ min⁻¹, $k_{-10}=8.0\times 10^{-4}$ min⁻¹, $pK_{a_1}=4.9$, $pK_{a_2}=8.1$. Me)/4a-In(H,Me) = 4.4 and 6.9 respectively. Thus, in contrast to the SO₃²⁻ addition to 10-(2',6'-dimethylphenyl)-3-methylisoalloxazine-6,8-disulfonate,7 the 5adduct is more thermodynamically stable, but importantly the equilibrium constants are close to unity. This isomerization undoubtedly occurs via a tight ion pair (eq 5). Comparison of the pH dependence of the

$$H_3C$$
 H_3C
 H_3C

conversion of 4a-InH to Fox (aerobic) and FH2 (anaerobic, argon atmosphere) in 50/50 ethanol-water (v/v),14 revealed that under anaerobic conditions the pH-log $k_{\rm obsd}$ profile below pH 3 was depressed by about 0.9 log units, the spontaneous terms were undetectable, and the HO- catalyzed conversion of 4a-InH to FH2 or Fox possessed the same rate constants. The acid catalyzed conversions to FH2 and Fox may logically be considered to proceed via a carbonium ion pair (eq 6). The log of

the second-order rate constants for H₃O⁻, HCOOH, and CH₃COOH catalysis (aerobic, H₂O) describe a linear relationship (deviation = 0.0) of slope -0.5when plotted vs. pK_a of the acids 15 establishing general acid catalysis as indicated in eq 6. The spontaneous terms k_1 , k_3 , k_6 , and k_8 (Scheme I) represent direct oxidation. The rate ratio for spontaneous oxidations (k_3) of 4a-adducts (4a-InH/4a-InMe = 0.53) dictates little charge on the indole nitrogen and, therefore, little carbonium ion character (possibly direct O₂ oxidation of substrate). In contrast, the ratio of rate constants for spontaneous (k_6) oxidation of neutral 5-adducts (5-InH/ 5-InMe = 0.14) dictates a more significant (+) charge delocalization to the indole nitrogen and therefore greater carbonium ion character in the transition state (oxidation of the ion pair by O_2).

(14) Because of the sparing solubility of 3-methyl-1,5-dihydrolumi-

flavin in H₂O these comparative studies necessitated a mixed solvent. (15) Second-order rate constants for H₂O⁻ = 22 M^{-1} min⁻¹, for HCOOH = 3.53 \times 10⁻² M^{-1} min⁻¹ and for CH₂COOH = 1.21 \times 10⁻² M^{-1} min⁻¹ based on buffer dilution plots at three concentrations at each of three pH values.

Since the HO⁻ catalyzed conversion of 4a-InH to both $F_{\rm ox}$ and FH_2 (not seen with 4a-InMe) is dependent upon the same rate constant, the mechanism can only represent an E-2 elimination to provide FH_2 (eq 7). The

$$\begin{array}{c} \text{CH}_{3} \\ \text{N} \\ \text{N} \\ \text{H} \\ \text{CH}_{2} \\ \text{N} \\ \text{H} \\ \text{H}_{2} \\ \text{O} \end{array}$$

3-hydroxymethylindole

log of the second-order rate constants for HO⁻, CO₃²⁻, and HPO₄²⁻ dictate a Brönsted line (deviation = 0.0) of slope $+0.5^{16}$ in accord with general-base catalysis as in eq 7.

These results suggest that in some flavin oxo-reduction reactions: (1) formation of a 5-adduct may lead to a 4a-adduct (dependent upon the carbonium ion stability of the migrating group⁵) prior to base catalyzed formation of oxidized substrate and FH₂, (2) formation of FH₂ from 5- and (appropriate) 4a-adducts is general-acid and general-base catalyzed, (3) formation of either a 4a- or 5-adduct may lead to oxidized substrate without reduction of F_{ox}, and (4) the stabilities of the 4a- and 5-adduct are such that, as intermediates, they should be observable, particularly in a model reaction. The elimination reaction of eq 7 represents an experimental verification of the feasibility of the Hamilton⁴ mechanism for flavin catalysis in appropriate cases.³

Neutral Tris(o-benzoquinone) Complexes of Chromium, Molybdenum, and Tungsten

Sir:

Considerable attention has been directed at the coordination properties of bidentate ligands which form unsaturated five-membered chelate rings with metal ions. Interest in these systems stems, in part, from the facile electrochemical properties observed for such complexes. A large majority of the ligands used in these studies have contained nitrogen and sulfur donor atoms. In an effort to investigate the chemical and structural properties of various related oxygen donor ligands, we have begun a study of simple binary metal-o-benzo-quinone complexes.

Reflux of o-tetrachlorobenzoquinone (1) with carbonyls of Cr, Mo, and W in benzene yields diamagnetic, neutral tris complexes of the metals according to reaction 1.² The complexes are only slightly soluble in

$$M(CO)_{6} + Cl O \xrightarrow{C_{6}H_{6}, N_{2}} \begin{bmatrix} Cl O & C_{6}H_{6}, N_{2} \\ Cl O & Cl O \end{bmatrix}$$

$$M = Cr, Mo, W$$

$$1$$

$$(1)$$

benzene and may be isolated from the reaction mixture by reducing the volume of the cooled solution.3 In solid they are moderately air stable⁴ and are highly colored: red-purple for Cr(O₂C₆Cl₄)₃, violet and brown for the Mo and W complexes. Infrared spectra show no bands above 1550 cm⁻¹ consistent with oxygenbonded, reduced o-benzoquinone ligands. 5 Spectral bands for Cr(O₂C₆Cl₄)₃ are sharp and agree with spectra reported previously for chelated o-tetrachlorobenzoquinone complexes. 6 Spectra for Mo(O₂C₆Cl₄)₃ and its W analog contain broader bands which in some cases are split into two distinct sets. Electronic spectra of the complexes show similar trends.⁷ The spectrum of the Cr complex is well resolved while the Mo and W complexes show only large broad bands. The electrochemical properties of all three complexes have been examined using cyclic voltammetry.8 The Mo and W complexes undergo one electron reduction reactions irreversibly while the Cr complex undergoes three reversible oxidation steps at +0.12, +0.54, and +0.88 V, with reduction of $Cr(O_2C_6Cl_4)_3^{3+}$ occurring at +0.07, +0.41, and +0.77 V. Attempts are currently underway to examine each member of this series.

The complex $Cr(O_2C_6Cl_4)_3$ is clearly different from its Mo and W analogs and also from related 1,2-dithiolene
