# Nitrogen Dioxide Catalyzed Geometric Isomerization of Olefins. Isomerization Kinetics of the 2-Butenes and 

 the 2-PentenesJ. L. Sprung, H. Akimoto, ${ }^{1}$ and J. N. Pitts, Jr.*<br>Contribution from the Department of Chemistry, University of California, Riverside, California 92502. Received February 21, 1974

#### Abstract

Arrhenius parameters have been determined for the $\mathrm{NO}_{2}$ catalyzed geometric isomerization of the 2-butenes and the 2-pentenes. For cis-2-butene, trans-2-butene, cis-2-pentene, and trans-2-pentene respectively $E$, $\mathrm{kcal} \mathrm{mol}{ }^{-1}=11.8,12.2,11.2$, and 12.5 and $\log A, 1 . \mathrm{mol}^{-1} \mathrm{sec}^{-1}=7.86,7.65,7.49$, and 7.72 over the temperature ranges $298-366,297-370,298-381$, and $298-382^{\circ} \mathrm{K}$. Combination of these results with the results of thermochemical calculations permits calculation of $298^{\circ} \mathrm{K}$ rate constants for $\mathrm{NO}_{2}$ addition to the double bond of ten simple olefins. These rate constants suggest that this reaction is unimportant in the bulk consumption of atmospheric olefin pollutants.

PPreviously we reported that $\mathrm{NO}_{2}$ catalyzes the thermal geometric isomerization of the 2-butenes and the 2-pentenes. ${ }^{2}$ By analogy to previous studies of radical catalyzed geometric olefin isomerizations, ${ }^{3}$ we suggested that the isomerization proceeded by $\mathrm{NO}_{2}$ addition to the olefin double bond to form a nitroalkyl radical, followed by bond rotation and loss of $\mathrm{NO}_{2}$ to form the isomeric olefin. ${ }^{2 a}$ We also noted that in a polluted urban atmosphere capture of the intermediate nitroalkyl radical by molecular oxygen would constitute a thermal pathway for the atmospheric oxidation of olefin pollutants which, if fast enough, could be of considerable significance for the formation of smog. In this paper we described the results of detailed studies of the kinetics of geometric isomerization of the 2-butenes and the 2 -pentenes and the use of these results to estimate the importance for the consumption of atmospheric olefin pollutants of processes initiated by $\mathrm{NO}_{2}$ addition to an olefin double bond.

## Experimental Section

The chemicals, apparatus, and analytical methods used in this study have been described in two previous papers. ${ }^{2}$

## Results

The equations used to develop the experimental data were identical for all four olefins. They will be described only as they apply to cis-olefin. Exchanging the symbols C and T will yield the corresponding equations for trans-olefin.

For the reaction

$$
\begin{equation*}
c i \text {-olefin } \xrightarrow{\mathrm{NO}_{2}} \text { trans-olefin } \tag{1}
\end{equation*}
$$

the initial rate of isomerization at low conversion may be written ${ }^{2 a}$

$$
\begin{equation*}
\mathrm{d}[\mathrm{~T}] / \mathrm{d} t=k_{\mathrm{ois}}\left[\mathrm{NO}_{2}\right]_{[ }[\mathrm{C}]_{0} \tag{2}
\end{equation*}
$$

where $k_{\text {cis }}$ is the experimentally determined rate constant, T and C denote trans- and cis-olefin and the zero

[^0]subscripts denote initial concentrations. This expression may also be written
\[

$$
\begin{equation*}
[\mathrm{T}]_{t} /[\mathrm{C}]_{0}=k_{\mathrm{cis}}\left[\mathrm{NO}_{2}\right]_{0} t \tag{3}
\end{equation*}
$$

\]

 $[\mathrm{T}]_{l}$ as a function of time $(t)$, the observed rate constant, $k_{\text {cis }}$, can be determined easily and precisely.

All experiments were run to conversions of less than $5 \%$. As expected for such low conversions, the observed dependence of $\left.[\mathrm{C}]_{t} / \mathrm{T}\right]_{t}$ on $t$ was always linear. Figure 1 illustrates the precision of the linearity routinely obtained. Nevertheless, this apparent linearity must mask the perturbing effects of some reverse isomerization.

Normal kinetic treatment of the following reaction scheme

$$
\begin{equation*}
\text { cis-olefin }+\mathrm{NO}_{2} \underset{k_{\text {trans }}}{\stackrel{k_{\text {cis }}}{\leftrightarrows}} \mathrm{NO}_{2}+\text { trans-olefin } \tag{4}
\end{equation*}
$$

yields eq 5 , where $K_{\mathrm{TC}}=k_{\text {trans }} / k_{\text {cis }}$. Iterative use of

$$
\begin{align*}
k_{\mathrm{ois}} t=-\frac{1}{\left[1+K_{\mathrm{Tc}}\right]\left[\mathrm{NO}_{2}\right]_{0}} & \times \\
& \ln \left\{1-\left[1+K_{\mathrm{TC}}\right] \frac{[\mathrm{T}]_{t}}{[\mathrm{C}]_{0}+[\mathrm{T}]_{0}}\right\} \tag{5}
\end{align*}
$$

eq 5 allowed the raw rate constants ( $k_{\text {cis }}$ or $k_{\text {trans }}$ ) calculated using eq 3 to be corrected for the perturbing effects of reverse isomerization. To do this the raw values for $k_{\text {cis }}$ and $k_{\text {trans }}$ were used to calculate an initial set of Arrhenius parameters for these rate constants. An initial value of $K_{\mathrm{TC}}$ (or $K_{\mathrm{CT}}$ ) was then calculated from these Arrhenius parameters. Substitution of this value into eq 5 now allowed a new set of values for $k_{\text {iis }}$ (or $k_{\text {trans }}$ ) to be calculated. This process was repeated until a consistent set of values was obtained for $k_{\text {cis }}$ and $k_{\text {trans }}$. These values and our experimental conditions are tabulated in a supplemental table presented in the microfilm edition of this journal.

## Arrhenius Parameters

Figures 2 and 3 present plots of $\log k$ vs. $\theta^{-1}$ where $\theta$ $=2.3 R T$. The lines are the least-squares lines calculated from the data presented in the microfilm edition.

Figure 1. Plot of the mole fraction of trans-2-butene os. time for the cis- to trans- $\mathrm{NO}_{2}$ catalyzed geometric isomerization of cis-2butene. The least-squares slope of the plot is $2.64 \pm 0.03 \times 10^{-4}$ $\min ^{-1}$. Reaction conditions were 9.00 Torr of cis-2-butene, 0.100 Torr of $\mathrm{NO}_{2}$, and $54.4 \pm 0.2^{\circ}$. The nonzero intercept is due to the presence of a trace of trans-2-butene impurity in the starting cis-2butene.

Figure 2. Arrhenius parameters for the $\mathrm{NO}_{2}$ catalyzed geometric isomerization of cis- or trans-2-butene. Plot of $\log k$ vs. $\theta^{-1}$ where $\theta=2.3 R T$ : ( $O$ ) cis-2-butene; ( $\bullet$ ) trans-2-butene.

The slope and intercept of each least-squares line give the Arrhenius parameters of that reaction. Table I

Table I. Arrhenius Parameters for the $\mathrm{NO}_{2}$ Catalyzed Geometric Isomerization of the 2 -Butenes and the 2-Pentenes

| Olefin | $E, \mathrm{kcal} \mathrm{mol}^{-1}$ | $\log A, 1 . \mathrm{mol}^{-1} \mathrm{sec}^{-1}$ |
| :--- | :---: | :---: |
| cis-2-Butene | $11.81 \pm 0.083$ | $7.861 \pm 0.058$ |
| trans-2-Butene | $12.19 \pm 0.118$ | $7.652 \pm 0.081$ |
| cis-2-Pentene | $11.23 \pm 0.092$ | $7.494 \pm 0.052$ |
| trans-2-Pentene | $12.48 \pm 0.088$ | $7.720 \pm 0.059$ |

Figure 3. Arrhenius parameters for the $\mathrm{NO}_{2}$ catalyzed geometric isomerization of cis- or trans-2-pentene. Plot of $\log k$ vs. $\theta^{-1}$ where $\theta=2.3 R T$ : ( $O$ ) cis-2-pentene; ( $)$ trans-2-pentene.
summarizes these results. For reasons presented in the Discussion, we believe that the $E$ value for trans-2butene is about 0.6 kcal too low which would make the value of $\log A$ low by about $0.3 \log$ units.

## Discussion

The reaction of $\mathrm{NO}_{2}$ with simple olefins is mechanistically and kinetically quite complex. ${ }^{4}$ Because of this, the easiest way to determine an upper limit for the rates of processes initiated by $\mathrm{NO}_{2}$ addition to an olefin double bond is to determine the rate constant for the initial addition step. As is described below, this can be conveniently done by combining our present experimental results with the results of a number of thermochemical calculations.

Rate Constants. For the reaction

1
2
the rate constants, $k_{\mathrm{a}}$ and $k_{\mathrm{b}}$, may be expressed in Arrhenius form as follows

$$
\begin{equation*}
k_{\mathrm{a}}=A_{\mathrm{a}} e^{-E_{\mathrm{a}} / R T} \text { and } k_{\mathrm{b}}=A_{\mathrm{b}} e^{-E_{\mathrm{b}} / R T} \tag{7}
\end{equation*}
$$

Jaffe in "Chemical Reactions in Urban Atmospheres," C. S. Tuesday, Ed., Elsevier, New York, N. Y., 1971; (e) S. C. Chao and S. Jaffe, J. Chem. Phys., 56, 1987 (1972); (f) B. V. Ashmead and J. H. Thomas, 14th Symposium on Combustion, The Combustion Institute, 1973, p 493.
where $k_{\mathrm{a}} / k_{\mathrm{b}}=K_{\mathrm{ab}}$ and $-R T \ln K_{\mathrm{ab}}=\Delta H_{\mathrm{ab}}{ }^{\circ} \cdot \mathrm{c}$ $T \Delta S_{\mathrm{ab}}{ }^{\mathrm{o}, \mathrm{c}}$. But $E_{\mathrm{a}}=\Delta H_{\mathrm{ab}}{ }^{0} \cdot \mathrm{c}+E_{\mathrm{b}}, A_{\mathrm{a}}=A_{\mathrm{b}} e^{\Delta S_{\mathrm{ab}}{ }^{\mathrm{o}, 0 / R}}$, and $A_{\mathrm{b}}=(e k T / h) e^{\Delta S_{\mathrm{b}} \neq / R}$. So, if $\Delta H_{\mathrm{ab}}{ }^{\circ}{ }^{\circ} \mathrm{c}, E_{\mathrm{b}}, \Delta S_{\mathrm{ab}}{ }^{\circ}{ }^{\circ}$, and $\Delta S_{\mathrm{b}} \neq$ are known, $k_{\mathrm{a}}$ may be calculated. As is described in the Appendix, $\Delta H_{\mathrm{ab}}{ }^{\circ}, \mathrm{c}, \Delta S_{\mathrm{ab}}{ }^{\circ}, \mathrm{c}$, and $\Delta S_{\mathrm{b}} \neq$ can be calculated or estimated for a number of simple olefins by thermochemical or incremental methods. ${ }^{\text {T }}$ Therefore, if $E_{\mathrm{b}}$ can be determined, $k_{\mathrm{a}}$ can be calculated.

Two facts permit $E_{\mathrm{b}}$ to be determined. First, for simple olefins $E_{\mathrm{b}}$ is unlikely to be very sensitive to either the nature of the substituents $\left(\mathrm{R}_{1}, \mathrm{R}_{2}, \mathrm{R}_{3}\right.$, and $\mathrm{R}_{4}$ ) or the conformation (cis or trans) of the nitroalkyl radical 2 . Therefore, $E_{\mathrm{b}}$ ought to have nearly the same value for most simple olefins. Second, as is shown below, the rate constants ( $k_{\text {eis }}$ or $k_{\text {trans }}$ ) for the $\mathrm{NO}_{2}$ catalyzed geometric isomerization of cis- or trans-2-butene or -2pentene may be expressed as functions of only $E_{\mathrm{b}}$ and several fundamental constants ( $e, k, h$ ) and calculable thermodynamic quantities $\left(\Delta S_{\mathrm{b}}{ }^{\mp}, \Delta S_{\mathrm{ab}}{ }^{\circ}{ }^{\circ}, \Delta H_{\mathrm{ab}}{ }^{\circ}, \mathrm{c}\right.$, and $\Delta H_{\mathrm{I}}{ }^{\circ}, \mathrm{c}$, which is defined below). Therefore, our experimental rate constants may be used to calculate a value for $E_{\mathrm{b}}$ which will be applicable to most other simple olefins.

The $\mathrm{NO}_{2}$ catalyzed geometric isomerization of 2butene or 2-pentene most likely proceeds ${ }^{2 a, 3}$ by the following mechanism

Application of the steady state approximation to the nitroalkyl radical intermediates, $\mathrm{I}_{1}$ and $\mathrm{I}_{2}$, yields the following expression, in which $K_{i j}=K_{i} / K_{j}$, for the rate of disappearance of cis-olefin.

$$
\begin{align*}
-\frac{\mathrm{d}[\mathrm{C}]}{\mathrm{d} t}=\left\{\frac{K_{\mathrm{ab}} k_{\mathrm{c}}}{1+K_{\mathrm{cb}}+K_{\mathrm{o}^{\prime} \mathrm{b}},}\right\} & {\left[\mathrm{NO}_{2}\right]_{0} \times } \\
& \left\{[\mathrm{C}]_{0}-\left[1+\frac{K_{\mathrm{a}^{\prime} \mathrm{b}}, k_{\mathrm{c}^{\prime}}}{K_{\mathrm{ab}} k_{\mathrm{c}}}\right][\mathrm{T}]\right\} \tag{9}
\end{align*}
$$

Stand., No. 21 (1970).

Flgure 4. Schematic energy surface for the $\mathrm{NO}_{2}$ catalyzed geometric isomerization of a simple olefin, illustrating the relations between the various thermochemical energy parameters used in this paper.

Because $K_{\mathrm{cb}} \approx K_{\mathrm{c}^{\prime} \mathrm{b}^{\prime}} \gg 1$, for low conversions where $[\mathrm{T}] \ll\left[\mathrm{C}_{0}\right]$ this expression may be simplified and rearranged ${ }^{2 a}$ to give

$$
\begin{equation*}
k_{\mathrm{cis}}=k_{\mathrm{a}} /\left(1+\frac{K_{\mathrm{c}^{\prime} b^{\prime}}}{K_{\mathrm{cb}}}\right) \tag{10}
\end{equation*}
$$

where

$$
\frac{K_{\mathrm{c}^{\prime} \mathrm{b}^{\prime}}}{K_{\mathrm{cb}}}=\frac{A_{\mathrm{c}^{\prime}} A_{\mathrm{b}}}{A_{\mathrm{c}} A_{\mathrm{b}^{\prime}}} e^{\left[\left(E_{\left.\left.\mathrm{c}^{-}-E_{\mathrm{c}^{\cdot}}\right)+\left(E_{\mathrm{b}}-E_{\mathrm{b}}\right)\right] / R T}\right.\right.}
$$

Figure 4 schematically depicts the energy surface for the $\mathrm{NO}_{2}$ catalyzed geometric isomerization of 2-butene or 2-pentene. In Figure $4 \Delta H_{\mathrm{r}}{ }^{\circ}, \mathrm{c}$ is the enthalpy change produced by the isomerization and

$$
\begin{align*}
\Delta H_{\mathrm{I}}{ }^{0, \mathrm{c}} & =E_{\mathrm{c}}-E_{\mathrm{c}^{\prime}} \\
& =\Delta H_{\mathrm{r}}^{0, \mathrm{c}}+\Delta H_{\mathrm{a}^{\prime} \mathrm{b}^{\prime}, \mathrm{c}}-\Delta H_{\mathrm{ab}}{ }^{0, \mathrm{c}} \tag{11}
\end{align*}
$$

Because $\Delta H_{\mathrm{r}}{ }^{\circ}, \mathrm{c}$ is known ${ }^{2 \mathrm{~b}}$ and $\Delta H_{\mathrm{ab}}{ }^{0.0}$ and $\Delta H_{\mathrm{a}^{\prime} \mathrm{b}^{\prime}}{ }^{0 . \mathrm{c}}$ are calculable (see Appendix), $\Delta H_{\mathrm{I}}{ }^{\circ} \mathrm{c}$ may be calculated.

Because the moments of inertia for rotation about the central carbon-carbon bond in the radicals, $\mathrm{I}_{1}$ and $\mathrm{I}_{2}$, are the same, ${ }^{1 \mathrm{a}} A_{\mathrm{c}}=A_{\mathrm{o}^{\prime}}$. Because $\Delta S_{\mathrm{b}} \ddagger=\Delta S_{\mathrm{b}^{\prime}} \ddagger$ (see supplemental material), $A_{\mathrm{b}}=A_{\mathrm{b}^{\prime}}$. Therefore, since $E_{\mathrm{b}} \cong E_{\mathrm{b}^{\prime}}$, eq 12 reduces to

$$
\begin{equation*}
k_{\mathrm{cis}}=k_{\mathrm{a}} /\left\{1+e^{\Delta H_{\mathrm{I}}{ }^{\circ} \cdot \mathrm{c} / R T}\right\} \tag{12}
\end{equation*}
$$

Appropriate substitution into eq 12 yields eq 13 , where $k_{\mathrm{x}}$ represents either $k_{\mathrm{cis}}$ or $k_{\text {trans }}$ and in which only $E_{\mathrm{b}}$ is unknown.

$$
\begin{equation*}
k_{\mathrm{x}}=\frac{e k T}{h} \frac{e^{\left[\left(\Delta S_{\mathrm{b}} \mp_{+\Delta S_{\mathrm{ab}}}^{\left.0.0) T_{-}\left(E_{\mathrm{b}}+\Delta H_{\mathrm{ab}} 0.0\right)\right] / R T}\right.\right.}}{1+e^{\Delta H_{\mathrm{I}}{ }^{0}, \mathrm{c} / R T}} \tag{13}
\end{equation*}
$$

Best agreement with experiment is obtained for $E_{\mathrm{b}}=$ $11.8 \mathrm{kcal} \mathrm{mol}^{-1}$. Table II compares the experimental

Table II. Comparison of Calculated and Experimental $298^{\circ} \mathrm{K}$ Rate Constants for the $\mathrm{NO}_{2}$ Catalyzed Geometric Isomerization of the 2 -Butenes and the 2 -Pentenes

| Olefin | Calcd | $k_{\mathrm{x}}{ }^{298}, \mathrm{l} \mathrm{mol}^{-1} \mathrm{sec}^{-1}$ |
| :--- | :--- | :--- |
| cis-2-Butene | 0.150 | Exptl |
| trans-2-Butene | 0.047 | 0.159 |
| cis-2-Pentene | $0.164^{a}$ | 0.053 |
| trans-2-Pentene | $0.044^{a}$ | 0.183 |

${ }^{a}$ Because 2-pentene is unsymmetrical, it can isomerize by two reaction pathways distinguished by $\mathrm{NO}_{2}$ addition at opposite ends of the double bond. Therefore, for 2-pentene the calculated values of $k_{x}{ }^{298}$ were obtained by summing the values of the rate constants calculated for each of the two isomerization pathways.

${ }^{a}$ For unsymmetrical olefins two reaction pathways are possible. Path I always denotes attack by $\mathrm{NO}_{2}$ on that end of the double bond which is either less substituted or bears the smaller alkyl group. Thus, for propylene path I is initiated by $\mathrm{NO}_{2}$ addition to the terminal methylene carbon and path II by $\mathrm{NO}_{2}$ addition to the central methine carbon. ${ }^{\circ}$ Because unsymmetrical olefins have two modes of addition (paths I and II), the overall rate constant for $\mathrm{NO}_{2}$ addition to the double bond equals the sum of the rate constants for the pathways I and II.
rate constants ( $k_{\mathrm{x}}$ ) measured for these isomerizations to the values calculated using eq 13 with $E_{\mathrm{b}}=11.8 \mathrm{kcal}$ $\mathrm{mol}^{-1}, \Delta H_{\mathrm{I}}{ }^{\circ} \mathrm{c}$ equal to the values calculated using eq 11 , and values of $\Delta S_{\mathrm{b}}{ }^{ \pm}, \Delta S_{\mathrm{ab}}{ }^{\circ}{ }^{\circ \mathrm{c}}$, and $\Delta H_{\mathrm{ab}}{ }^{\circ} . \mathrm{c}$ taken from a supplemental table presented in the microfilm edition. As Table II shows, the agreement between calculation and experiment is remarkably good.
Table III presents the values of $A_{\mathrm{b}}, k_{\mathrm{b}}, A_{\mathrm{a}}, E_{\mathrm{a}}$, and $k_{\mathrm{a}}{ }^{298}$ calculated for ten simple olefins using data taken from the supplemental tables and $E_{\mathrm{b}}=11.8 \mathrm{kcal} \mathrm{mol}^{-1}$. Only one direct comparison with experimental results other than our own is possible and that is for acetylene, for which a value of $k_{\mathrm{a}}{ }^{298}=0.0171 . \mathrm{mol}^{-1} \mathrm{sec}^{-1}$ may be calculated from the Arrhenius parameters $\left[\log A_{\mathrm{a}}, 1\right.$. $\left.\mathrm{mol}^{-1} \mathrm{sec}^{-1}=9.1 ; E_{\mathrm{a}}=15.0 \mathrm{kcal} \mathrm{mol}{ }^{-1}\right]$ determined by Thomas ${ }^{4 a}$ over the temperature range $170 \sim 220^{\circ}$. Again the agreement with experiment is remarkably good, which suggests that our calculated values of $k_{\mathrm{a}}{ }^{298}$ are surely accurate to an order of magnitude and quite possibly to a factor of 2 or 3 .

Arrhenius Parameters. Equation 12 provides a basis for comparing our calculated 2-butene and 2-pentene Arrhenius parameters for $k_{a}$ to our experimental 2butene and 2-pentene Arrhenius parameters for $k_{\mathrm{x}}=$ $k_{\text {cis }}$ or $k_{\text {trans }}$. To do this the denominator of eq 12 is approximated by an exponential

$$
\begin{equation*}
\alpha e^{\Delta h / R T}=1+e^{\Delta H_{\mathrm{I}}{ }^{\circ} .0 / R T} \tag{14}
\end{equation*}
$$

Substitution of this approximation into eq 12 and expression of $k_{\mathrm{a}}$ and $k_{\mathrm{x}}$ in Arrhenius form yields

$$
\begin{equation*}
k_{\mathrm{x}}=A_{\mathrm{x}} e^{-E_{\mathrm{x}} / R T}=\frac{A_{\mathrm{a}}}{\alpha} e^{-\left(E_{\mathrm{a}}+\Delta h\right) / R T} \tag{15}
\end{equation*}
$$

Division of the first derivative of eq 15 by that equation yields an expression for $\Delta h$ as a function only of $\Delta H_{\mathrm{I}}{ }^{\circ}{ }^{\circ}$ for which values are available. Since $\alpha$ can be determined from $\Delta h, A_{\mathrm{a}} / \alpha$ and $E_{\mathrm{a}}+\Delta h$ can be calculated. Table IV summarizes the results of these calculations. Since the comparison is pertinent, Table IV also compares our calculated Arrhenius parameters for $k_{\mathrm{a}}$ for acetylene to the experimental values of Thomas. ${ }^{4 a}$

Table IV shows that except for trans-2-butene the calculated Arrhenius preexponential factors are all low ${ }^{6}$ by a factor of about 2 and the calculated activation energies are all low by about $0.4 \mathrm{kcal} \mathrm{mol}^{-1}$. This suggests that our experimental Arrhenius parameters for trans-2-butene are most probably in error and ought to be changed to values of $E_{\mathrm{x}}=12.8 \mathrm{kcal} \mathrm{mol}^{-1}$ (in order to make $E_{\mathrm{x}}{ }^{\text {cis }}-E_{\mathrm{x}}{ }^{\text {trans }}=\Delta H_{\mathrm{r}}{ }^{\circ}, \mathrm{c}=1.0 \mathrm{kcal} \mathrm{mol}^{-1}$ and $A_{\mathrm{x}}=9.6 \times 10^{7} 1 . \mathrm{mol}^{-1} \mathrm{sec}^{-1}$ (in order to make $A_{\mathrm{x}} e^{-E_{\mathrm{x}} / R T}=k_{\mathrm{x}}=0.0531 . \mathrm{mol}^{-1} \mathrm{sec}^{-1}$, when $T=$ $298^{\circ} \mathrm{K}$ and $\left.E_{\mathrm{x}}=12.8 \mathrm{kcal}_{\mathrm{mol}}{ }^{-1}\right)$.

Jaffe has measured the temperature dependence ( 25 to $100^{\circ}$ ) of the rate of disappearance of $\mathrm{NO}_{2}$ upon reaction with seven simple olefins. ${ }^{4 \mathrm{~d}}$ Regardless of the olefin used, the reaction was second order overall and first order both in olefin and $\mathrm{NO}_{2}$. Table V tabulates the Arrhenius parameters determined by Jaffe for these reactions.

Comparison of the Arrhenius parameters in Table V to those in Table IV strongly indicates that the ratedetermining step of Jaffe's reactions was not addition of $\mathrm{NO}_{2}$ to the olefin double bond. For ethylene Jaffe has proposed ${ }^{4 d}$ the following initial reaction sequence

If $k_{t}<k_{\mathrm{a}} \ll k_{\mathrm{b}}$, which our calculations show to be the case, then $k_{\text {obsd }}=\left(k_{\mathrm{a}} / k_{\mathrm{b}}\right) k_{t}$ and therefore

$$
\begin{align*}
E_{t} & =E_{\mathrm{obsd}}-\Delta H_{\mathrm{ab}}^{0 . \mathrm{c}} \\
\log A_{t} & =\log A_{\mathrm{obsd}}-\frac{\Delta S_{\mathrm{ab}}^{0 . \mathrm{c}}}{2.3 R} \tag{17}
\end{align*}
$$

Substitution into eq 17 of values of $\Delta H_{a b}{ }^{\circ}, \mathrm{c}$ and $\Delta S_{a b}{ }^{0, c}$ taken from the supplemental tables and of Jaffe's values
(6) In our calculation of $\Delta S_{\mathrm{b}} \neq$ (see Appendix) we have assumed a two-thirds decrease in the barrier to internal rotation of the $\mathrm{NO}_{2}$ group. If passage to the transition state ( $T^{\ddagger}$ ) actually lowers this barrier to zero, then our calculated preexponential factors ( $A_{\mathrm{a}}$ ) would all increase by a factor of about 1.4.

${ }^{a}$ Reference 5d.
of $E_{\text {obsd }}$ and $\log A_{\text {obsd }}$ yields the values of $E_{t}$ and $\log A_{t}$ listed in Table V. With the exception of isobutene, the values of $E_{t}$ or $\log A_{t}$ are quite similar as would be expected for substrates bearing different alkyl substituents but reacting via the same transition state. However, the values of $\log A_{t}$ appear ${ }^{7}$ to be low by at least two orders of magnitude, which suggests that these reactions do not have a cyclic four-center O -atom transfer as their ratedetermining step.

Air Pollution. Equation 18 formulates the ratio of the rate of consumption of an olefin (Ol) by ozone $\left(R_{\mathrm{O}_{3}}\right)$ to that by nitrogen dioxide $\left(R_{\mathrm{NO}_{2}}\right)$.

$$
\begin{equation*}
\frac{R_{\mathrm{O}_{3}}}{R_{\mathrm{NO}}}=\frac{k_{\mathrm{O}_{3}}}{k_{\mathrm{NO}_{2}}}\left[\mathrm{O}_{3}\right]\left[\frac{\left.\mathrm{Ol} \mathrm{O}_{2}\right]}{}\right] \frac{\mathrm{Ol}]}{[\mathrm{Ol}]} \tag{18}
\end{equation*}
$$

Substitution into this equation of a maximum value for $k_{\mathrm{NO}_{2}}$ and minimum values for $k_{\mathrm{O}_{3}}$ and the ratio of concentrations, $\left[\mathrm{O}_{3}\right] /\left[\mathrm{NO}_{2}\right]$, will yield a minimum value for the rate ratio, $R_{\mathrm{O}_{3}} / R_{\mathrm{NO}_{3}}$.

In polluted urban atmospheres ${ }^{8}$ the concentration of $\mathrm{NO}_{2}$ rarely exceeds that of $\mathrm{O}_{3}$ by more than a factor of 100. The rate constant for addition of $\mathrm{NO}_{2}$ to an olefin double bond ( $k_{\mathrm{a}}$ ) must be greater than the rate constant for consumption of $\mathrm{NO}_{2}$ by reaction with that olefin ( $k_{\mathrm{NO}_{2}}$ ). Table III shows that for simple olefins $k_{\mathrm{a}}{ }^{\max } \approx 10^{-1}$. Rate constants for the consumption of $\mathrm{O}_{3}$ by reaction with simple olefins ${ }^{9}$ range from $10^{3}$ to $10^{5}$ 1. $\mathrm{mol}^{-1} \mathrm{sec}^{-1}$, so $k_{O_{\mathrm{a}}}{ }^{\text {min }} \approx 10^{3}$. Substitution of these values in eq 20 yields a minimum value of $R_{\mathrm{O}_{3} / R_{\mathrm{NO}_{2}}=}=$ $10^{2}$, which shows that atmospheric reaction pathways initiated by $\mathrm{NO}_{2}$ addition to an olefin double bond cannot possibly be significant in the bulk consumption of olefin pollutants.

## Appendix: Calculation of Thermochemical Quantities for Reaction 6

Calculation of $\Delta H_{\mathrm{ab}}{ }^{\circ} . \Delta H_{\mathrm{ab}}{ }^{\circ}$ may be calculated in at least two ways from the data presented in the microfilm edition.

$$
\begin{align*}
& \underset{\mathbf{3}}{\mathrm{R}_{1} \mathrm{R}_{4} \mathrm{C}-\mathrm{CR}_{2} \mathrm{R}_{3}} \underset{\mathrm{R}_{1} \mathrm{R}_{4} \mathrm{C}-\mathrm{CR}_{4}^{\mathrm{C}} \mathrm{CR}_{2} \mathrm{R}_{3}}{\mathrm{~N}_{2} \mathrm{R}_{1} \mathrm{R}_{4} \mathrm{CH}-\mathrm{C}_{2} \mathrm{CR}_{2} \mathrm{R}_{3}} \\
& \Delta H_{\mathrm{ab}}{ }^{\circ}=D_{\pi}(1)-D_{\mathrm{C}-\mathrm{NO}_{2}}(2)  \tag{Al}\\
& \Delta H_{\mathrm{ab}}{ }^{\circ}=\Delta H_{\mathrm{f}}{ }^{\circ}(2)-\Delta H_{\mathrm{f}}{ }^{\circ}(1)-\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{NO}_{2}\right) \tag{A2}
\end{align*}
$$

$D_{\pi}(1), D_{\mathrm{C}-\mathrm{NO}_{2}}$ (2), and $\Delta H_{\mathrm{f}}{ }^{\circ}$ (2) are not directly available and must be calculated.

$$
\begin{array}{r}
D_{\pi}(1)=D_{\mathrm{C}-\mathrm{H}_{\alpha}}(4)+D_{\mathrm{C}-\mathrm{H}_{\beta}}(4)-D_{\mathrm{H}-\mathrm{H}}\left(\mathrm{H}_{2}\right)- \\
\Delta H_{\text {hydrogenation }}(1) \tag{A3}
\end{array}
$$

Taking $D_{\mathrm{C}-\mathrm{NO}_{2}}(3)$ to be a reasonable model for $D_{\mathrm{C}-\mathrm{sO}_{2}}$ (2) gives

$$
\begin{equation*}
D_{\mathrm{C}-\mathrm{NO}_{2}}(2)=\Delta H_{\mathrm{f}}^{\circ}(5)+\Delta H_{\mathrm{f}}^{\circ}\left(\mathrm{NO}_{2}\right)-\Delta H_{\mathrm{f}}^{\circ}(3) \tag{A4}
\end{equation*}
$$

Taking $D_{\mathrm{C}-\mathrm{H} \beta}(4)$ to be a reasonable model for $D_{\mathrm{C}-\mathrm{H}}(3)$ gives

$$
\begin{equation*}
\Delta H_{\mathrm{f}}^{\circ}(2)=\Delta H_{\mathrm{f}}^{\circ}(3)-\Delta H_{\mathrm{f}}^{\circ}(\mathrm{H})+D_{\mathrm{C}-\mathrm{H}_{\beta}}(4) \tag{A5}
\end{equation*}
$$

Appropriate combination of these equations followed by substitution of the values listed in the microfilm edition now permits two values to be calculated for $\Delta H_{\mathrm{ab}}{ }^{\circ}$. Conversion of the average of these two values for $\Delta H_{\mathrm{ab}}{ }^{\circ}$ to concentration units gives $\Delta H_{\mathrm{ab}}{ }^{\circ}{ }^{\circ}$. The results of these calculations are presented in the microfilm edition.

Calculation of $\Delta S_{\mathrm{ab}}{ }^{\circ}$

$$
\begin{equation*}
\Delta S_{\mathrm{ab}}^{\circ}=S^{\circ}(2)-S^{\circ}(1)-S^{\circ}\left(\mathrm{NO}_{2}\right) \tag{A6}
\end{equation*}
$$

Data sufficient for the calculation of $S^{\circ}(2)$ are unavailable. Instead, $S^{\circ}(2)$ has been estimated from $S^{\circ}(3)$ using the methods of Benson and coworkers. ${ }^{5}$ Appropriate corrections ${ }^{5 c}$ were made for changes in mass, spin, symmetry, and moments of inertia and rotational
barriers ${ }^{10}$ of internal roters. Where values of $S^{\circ}(3)$ were lacking, they were estimated by incremental or group additivity methods. ${ }^{5}$ Conversion of $\Delta S_{\mathrm{ab}}{ }^{\circ}$ to concentration units gives $\Delta S_{\mathrm{ab}}{ }^{0, \mathrm{c}}$. The results of these calculations are tabulated in the microfilm edition.

Estimation of $\Delta S_{\mathrm{b}} \neq, \quad \Delta S_{\mathrm{b}} \neq$ was estimated by summing the changes in rotational ${ }^{10}$ and vibrational ${ }^{14}$ entropy

[^1]produced in the nitroalkyl radical, I, upon passage to the transition state, $\mathrm{T}^{\mp}$. Equation A7 expresses this summation.
\[

$$
\begin{align*}
& \Delta S_{\mathrm{b}} \ddagger=S^{\circ}\left[\left(\mathrm{C}-\mathrm{NO}_{2}\right)_{\mathrm{rc}}+(\mathrm{C}-\mathrm{C})_{\mathrm{s}}{ }^{1300}+\right. \\
& \left(\mathrm{C}-\mathrm{C} \cdot \mathrm{NO}_{2}\right)_{\mathrm{b}}^{185}+2\left(\mathrm{NO}_{2}\right)^{170}{ }_{1 \mathrm{erock}}+\left(\mathrm{C}\left(\cdot \mathrm{NO}_{2}\right)+\right. \\
& \left.(\mathrm{C}-\mathrm{C})_{\mathrm{t}}\right]-S^{\circ}\left[\left(\mathrm{C}-\mathrm{NO}_{2}\right)_{\mathrm{s}}^{825}+(\mathrm{C}-\mathrm{C})_{\mathrm{s}}^{1000}+\right. \\
& \left(\mathrm{C}-\mathrm{C}-\mathrm{NO}_{2}\right)_{\mathrm{b}}{ }^{370}+2\left(\mathrm{NO}_{2}\right)^{500_{2 \mathrm{e} \text { rock }}+\left(\mathrm{C}\left(-\mathrm{NO}_{2}\right)+\right.} \\
& \quad(\mathrm{C}(-\mathrm{C})]+R \ln \left\{\sigma_{(2)} / \sigma_{(\mathrm{T} \neq)}\right\} \quad(\mathrm{A} \tag{A7}
\end{align*}
$$
\]

Equation A7 was formulated using the methods and terminology of Benson and O'Neal. ${ }^{\text {dd }}$ In formulating eq A7 all entropy terms of magnitude less than 0.1 gibbs $\mathrm{mol}^{-1}$ were neglected. The values of $\Delta S_{\mathrm{b}} \neq$ computed using eq A7 are listed in the microfilm edition.

Supplementary Materials Available. Two tables will appear following these pages in the microfilm edition of this volume of the journal. The first tabulates our experimental rate constants and the conditions of their measurement. The second summarizes the thermochemical quantities used in or calculated by the thermochemical methods described in the Appendix. Photocopies of the supplementary material from this paper only or microfiche ( $105 \times$ $148 \mathrm{~nm}, 24 \times$ reduction, negatives) containing all of the supplementary material for papers in this issue may be obtained from the Journals Department, American Chemical Society, 1155 16th St., N.W., Washington, D. C. 20036. Remit check or money order for $\$ 3.00$ for photocopy or $\$ 2.00$ for microfiche, referring to code number JACS-74-6549.

# A Long Path Infrared Spectroscopic Study of the Reaction of Methylperoxy Free Radicals with Nitric Oxide 

C. T. Pate, B. J. Finlayson, and J. N. Pitts, Jr.*<br>Department of Chemistry and Statewide Air Pollution Research Center, University of California, Riverside, California 92502. Received April 22, 1974

#### Abstract

The reaction of NO with $\mathrm{CH}_{3} \mathrm{O}_{2}$ radicals generated in the photooxidation of $\mathrm{CH}_{3} \mathrm{~N}_{2} \mathrm{CH}_{3}$ at $\lambda>320 \mathrm{~nm}$ was investigated at $23 \pm 2^{\circ}$ using long path infrared and gas chromatographic techniques. Reaction conditions were: $\mathrm{CH}_{3} \mathrm{~N}_{2} \mathrm{CH}_{3}, 33-369 \mathrm{mTorr} ; \mathrm{O}_{2}, 2200-5320 \mathrm{mTorr}$; and NO, $25-76 \mathrm{mTorr}$, at a total pressure of 760 Torr (He or $\mathrm{N}_{2}$ ). At short photolysis times, $\mathrm{CH}_{3} \mathrm{ONO}$ and $\mathrm{NO}_{2}$ were both identified as products with quantum yields of $1.7 \pm 0.2$ and $1.9 \pm 0.3$, respectively. HCHO was qualitatively identified in several runs by the chromotropic acid test. At longer reaction times, methyl nitrate also accumulated. These results suggest that the reaction $\mathrm{CH}_{3} \mathrm{O}_{2}+\mathrm{NO} \rightarrow \mathrm{CH}_{3} \mathrm{O}+\mathrm{NO}_{2}$ (7) is the only path for the reaction of methylperoxy radicals with nitric oxide under these conditions. $\mathrm{CH}_{3} \mathrm{O}$ - is then removed by the reactions: $\mathrm{CH}_{3} \mathrm{O} \cdot+\mathrm{NO}_{2} \rightarrow \mathrm{CH}_{3} \mathrm{ONO}_{2}$ ( 9 a ), $\mathrm{CH}_{3} \mathrm{O} \cdot+$ $\mathrm{NO}_{2} \rightarrow \mathrm{HCHO}+\mathrm{HONO}(9 b), \mathrm{CH}_{3} \mathrm{O}+\mathrm{NO} \rightarrow \mathrm{CH}_{3} \mathrm{ONO}(8 \mathrm{a})$, and $\mathrm{CH}_{3} \mathrm{O}+\mathrm{NO} \rightarrow \mathrm{HCHO}+\mathrm{HNO}$ (8b).

The reaction of alkylperoxy radicals with nitric oxide is generally assumed ${ }^{1-3}$ to proceed by the oxidation of nitric oxide to nitrogen dioxide with formation of an alkoxy radical

$$
\begin{equation*}
\mathrm{RO}_{2} \cdot+\mathrm{NO} \longrightarrow \mathrm{RO}+\mathrm{NO}_{2} \tag{1}
\end{equation*}
$$

[^2]Reaction 1 is believed to be an important route for oxidizing NO to $\mathrm{NO}_{2}$ in photochemical smog. In addition, the alkoxy radical, $\mathrm{RO} \cdot$, may react further in the atmosphere to produce $\mathrm{HO}_{2} \cdot{ }^{4}$ which also converts NO to $\mathrm{NO}_{2}$. However, a mass spectrometric study ${ }^{5}$ in-

[^1]:    (10) Both molecular dimensions ${ }^{17}$ and $A$ values ${ }^{12}$ suggest that, when estimating rotational barriers, a methyl group ought to be a satisfactory model for a nitro group. Accordingly, the saturated alkane, obtained by replacing the nitro group in the nitroalkane 3 by a methyl group, was used as a model for estimating rotational barriers in the nitroalkane 3. For example, propane was used as a model for nitroethane. Then, using the methods of Benson and coworkers, ${ }^{5}$ rotational barriers in the nitroalkyl radical 2 or the transition state $T \neq$ were estimated from the rotational barriers estimated for the nitroalkane 3. Rotational barriers in the saturated alkane model compounds were based on literature data. ${ }^{13}$
