(13) Studies on model compound i confirmed that the epoxidation was highly stereoselective with the angular methyl group having a very large influ-

ence on the steric course of the reaction. The nmr chemical shifts of the angular methyl groups and the splitting patterns of the methine protons supported our stereochemical assignments.

¹³C Nuclear Magnetic Resonance of [Rh₆(CO)₁₅C]²⁻

Sir:

The carbide atom in transition metal carbonyl cluster carbides has been claimed to result from two different sources: bonded carbon monoxide is believed to disproportionate to carbon and carbon dioxide,¹ and, recently, halocarbons such as CHCl₃² and CCl₄ have been found to be the source of the carbide atom, according to the reactions

$$6[RhCl_{6}]^{3-} + 23OH^{-} + 26CO + CHCl_{3} \xrightarrow{MeOH}{25^{\circ}, 1atm} [Rh_{6}(CO)_{15}C]^{2-} + 39Cl^{-} + 11CO_{2} + 12H_{2}O \quad (1)$$
(yield ~80%)
6[NMe_{3}Bz][Rh(CO)_{4}] + CCl_{4} \xrightarrow{i-PrOH}{25^{\circ}} [NMe_{3}Bz]_{2}[Rh_{6}(CO)_{15}C] + 4[NMe_{3}Bz]Cl + 9CO \quad (2) (yield ~90%)

Although we have observed that in both cases the carbide cluster is not obtained in the absence of the halocarbon, in view of the novelty of these syntheses we wished to have unequivocal proof of the source of the carbide atom in the $[Rh_6(CO)_{15}C]^{2-}$ dianion. To this end we have synthesized $[Rh_6(CO)_{15}]^{13}C]^{2-}$ (ca. 90% ¹³C) starting from ¹³CCl₄ and the $[Rh(CO)_4]^-$ anion, and the ¹³C nmr spectrum of this species has been recorded in perdeuterioacetone solution containing Cr(acac)₃ as relaxing agent.³ The resonance of the carbide carbon should show a septet pattern due to coupling with six equivalent rhodium atoms. Both at room temperature and at -70° , the spectrum (Figure 1a) shows a symmetrical five-line pattern and it seems probable that the outer lines of the expected septet are not resolved since the relative intensities of the five lines, 8.6:15.7:20.0:15.2:8.4, show better agreement with the relative intensities of a septet rather than a quintet pattern. The spacing between the lines is 13.7 \pm 2 Hz and this low value of ¹J (Rh-C_D) (see Figure 2) is consistent with the expected low s character of the rhodium-carbide bonds. The carbide resonance (264.7 ppm)⁴ occurs at very low field and is in the region found for carbonium ions⁵ and rhodium carbene complexes.⁶ The shortness of the carbide radii in similar clusters of ruthenium⁷ and iron⁸ is in favor of a positive and contracted carbide atom.

¹³CO interexchange with $[Rh_6(CO)_{15}C]^{2-}$ occurs very slowly at room temperature and atmospheric pressure. At 80° (in tetrahydrofuran solution) exchange is faster, but decomposition to give uncharacterised species also takes place. However, under these last conditions we were able to

Figure 1. The ¹³C nmr spectrum of (a) $[Rh_6(CO)_{15}]^{13}C]^{2-}$ (ca. 90% ¹³C) and (b) $[Rh_6(CO)_{15}C]^{2-}$ (ca. 42% ¹³CO) at -70° in perdeuterioacetone solution in the presence of Cr(acac)3.

Figure 2. The X-ray structure of $[Rh_6(CO)_{15}C]^{2-2}$

introduce 18.5 \pm 1% of ¹³CO into [Rh₆(CO)₁₅C]²⁻. The ¹³CO-enriched complex, $[Rh_6(CO)_{15}C]^2 - (42 \pm 1\% {}^{13}CO)$ was also prepared from CCl₄ and ${}^{13}CO$ -enriched $[Rh(CO)_4]^-$ (δ 206.33 ppm, ${}^{1}J(Rh-C)$ 74.7 \pm 1 Hz). In both cases the ¹³C nmr spectra at -70 and $+25^{\circ}$ were similar (see Figure 1b) and showed the absence of the carbide resonance at 264.7 ppm.

The inequivalent bridging carbonyls both appear as triplets (B, δ 225.2 ppm, ¹J(Rh-C) 30.8 ± 2 Hz; C, δ 236.3 ppm, ${}^{1}J(Rh-C)$ 51.8 ± 2 Hz) whereas the terminal carbonyl resonance (δ_A 198.1 ppm) is a doublet of doublets, which we believe is due to ${}^{1}J(Rh_{1}-C_{A})$ 77.1 ± 2 Hz and $^{2}J(Rh_{2}-C_{A})$ 3.9 ± 2 Hz (see Figure 2).9

In all the above cases the values of the chemical shifts for the carbonyl resonances are similar to those recently reported for related compounds,¹⁰ and generally an increase in rhodium-carbon bond length results in a decrease in $^{1}J(Rh-CO).$

Acknowledgments. We thank the Royal Society and the Accademia dei Lincei for postdoctoral fellowships (D.J.A.McC. and D.S. respectively), NATO for a grant, Dr. P. R. Mitchell for a gift of the ¹³CCl₄, and D. O. Smith for recording the ¹³C nmr spectra.

Sterol Biosynthesis from (3RS, 2R)-[2-14C,2-3H]-Mevalonic Acid in a Yeast Homogenate. Stereochemistry of the C-15 Tritium Atom^{1,2}

Sir:

Several years ago we described significant stereochemical differences in the elaboration of sterols by rat liver³ and by yeast⁴ enzymes. These observations were made during the investigation of the biosynthesis of sterols from (3RS, 2R)- $[2-{}^{14}C, 2-{}^{3}H]$ mevalonic acid (MVA) and $(3RS, 2S)-[2-{}^{14}C, 2-{}^{3}H]$ ¹⁴C,2-³H]MVA by a cell free yeast preparation.⁴ It was noticed that in this enzyme system essentially only C_{27} sterols were formed and that usually major amounts of radioactivity were incorporated 5.6 into cholesta-5,7,24-trien-3 β -ol (1) and 5α -cholesta-7,24-dien-3 β -ol (2). The (R)-1a and

• Carbon atoms derived from C-2 of MVA (14 C); T = 3 H; H_R and H_S refer to 2 pro R and 2 pro S hydrogens of MVA, respectively.

(R)-2a as well as (S)-1b and (S)-2b each retained four atoms of tritium and five atoms of ¹⁴C.⁴⁻⁶ We have proven⁴ that (R)-1a and (R)-2a were devoid of tritium atoms at C-7 while the (S)-1b and (S)-2b retained tritium atoms at C-7. This observation was in sharp contrast to the situation in rat liver systems³ in which the transformation of the $\Delta^{8(9)}$ sterol to the Δ^7 isomer proceeds with the loss of a hydrogen derived from 2 pro S of MVA.

It was deduced⁴⁻⁶ that the yeast (S) metabolites had tritium atoms at C: 1α ,7,22, and 26. The (R) metabolites⁴⁻⁶ had tritium atoms at C: 1β ,22 and 26. This left one isotopic hydrogen unaccounted for which was likely to be located 4.12at C-15. We therefore undertook to determine the location and the stereochemistry of the "fourth" tritium atom of the (R) metabolites.

The homogenate was prepared from aerobically grown yeast as previously reported.⁶ The (3RS, 2R)-[2-¹⁴C,2-³H]MVA (18 µCi of ¹⁴C; ³H: ¹⁴C ratio 10.7) was incubated⁶ with an aliquot of the homogenate corresponding to 1.5 g of wet cells under an atmosphere of O2. After conventional work-up⁶ the nonsaponifiable residue $(1.32 \times 10^7 \text{ dpm of})$ ¹⁴C) was acetylated and resolved into homogeneous trienacetate (1c) $(8.7 \times 10^4 \text{ dpm})$ and dien-acetate (2c) $(1.06 \times$ 10⁶ dpm of ¹⁴C). Hydrogenation⁷ (EA; Raney-Ni) of a mixture of 2c (4.8 × 10⁴ dpm of ¹⁴C) and cholesta-5,7dien-3 β -ol acetate resulted in [14C₅; ³H₄]-5 α -cholest-7-en-
