plings. Thus, the $J_{\mathrm{CC}} / J_{\mathrm{HH}}$ ratio should be in the range of $+(0.4)^{2}$ to $+(0.7)^{2}$, or +0.16 to +0.49 (because $J_{\mathrm{CC}} / J_{\mathrm{HH}}$ $=J_{\mathrm{CC}} / J_{\mathrm{CH}} \times J_{\mathrm{CH}} / J_{\mathrm{HH}}$ ). Indeed, the $J_{\mathrm{CC}} / J_{\mathrm{HH}}$ ratio (for $J_{14}$ of 1 and $J_{\mathrm{HH}}$ of acetylene ${ }^{9}$ ) is $+1.84 /+9.53=+0.2$.

Thus, in the acetylenic compound $\mathbf{1}$, the $J_{\mathrm{CC}}$ values do compare with geometrically equivalent $J_{\mathrm{CH}}$ and $J_{\mathrm{HH}}$ values in the manner that $J_{\mathrm{CH}}$ values compare with geometrically equivalent $J_{\mathrm{HH}}$ values. Evidence therefore continues to accumulate that carbon-13 behaves as proton in nmr couplings and that couplings involving carbon-13 have similar mechanisms to those involving proton.

Work is continuing to determine $J_{\mathrm{CC}} / J_{\mathrm{CH}}$, including signs, for multiply labeled olefinic and aliphatic compounds.

Acknowledgments. The authors wish to express their gratitude to the Robert A. Welch Foundation, Houston, Texas (Grant B-325), to North Texas State University Faculty Research, and to the donors of the Petroleum Research Fund, administered by the American Chemical Society (Grant PRF 7409-AC4,6), for financial support of this work.

## References and Notes

(1) Because of a lower magnetogyric ratio, carbon-13 couplings should be smaller than proton couplings (see ref 2).

(7) As a referee has pointed out, there may be some question whether the electronegative carboxylate group is a suitable replacement group for hydrogen, because this group may be expected to exert a considerable influence on the magnitude of the coupling constants. The carboxylate group does in fact enhance the coupling over the methyl group, and for the methyl substituent the $J_{\mathrm{CH}} / J_{\mathrm{HH}}$ or $J_{\mathrm{CC}} / J_{\mathrm{CH}}$ ratio is generally a little lower. To the best of our knowledge, the smallest such ratio is for $\mathrm{H}_{3} \mathrm{CC} \equiv \mathrm{CH} / \mathrm{HC} \equiv \mathrm{CH}$, viz., 0.31, H. Dreeskamp and E. Sackmann, $Z$. Phys. Chem., 34, 273 (1962).
(8) It is to be further noted that ${ }^{1} J_{\mathrm{CC}}\left(J_{34}\right)$ determined in this study is positive, just as was observed by Grant for acetic acid: D. M. Grant, J. Amer. Chem. Soc., 89, 2228 (1967).

## Comment Regarding the Rate Constant for the Reaction between 1,3-Diphenylisobenzofuran and Singlet Oxygen

## Sir:

Recently Matheson, et al., stated ${ }^{1}$ that the rate constant for reaction between 1,3-diphenylisobenzofuran (DPBF) and singlet oxygen ( ${ }^{( } \Delta$ ) reported by ourselves, ${ }^{2,3}$ and oth-
ers, ${ }^{4}$ is an order of magnitude too high and primarily reflects physical quenching of ${ }^{\prime} \triangle$ by DPBF rather than reactive quenching. This assertion is supported neither by our own laser photolysis data nor by data from several other laboratories.

While DPBF no doubt physically quenches ' $\Delta$ to some extent, an analysis of photooxidation efficiencies leads us to rule out this process as a major decay pathway. Under the conditions of our experiments ${ }^{3}$ the possible routes for ${ }^{1} \Delta$ decay are

$$
\left.\begin{array}{c}
{ }^{1} \Delta \xrightarrow{1^{1 / \tau}}{ }^{3} \Sigma \text { (solvent quenching) } \\
{ }^{1} \Delta+\mathrm{A} \xrightarrow{k_{q}}{ }^{3} \Sigma+\mathrm{A} \text { (physical quenching } \\
\text { by acceptor } \mathrm{A})
\end{array}{ }^{1} \Delta+\mathrm{A} \xrightarrow{k_{a}} \mathrm{AO}_{2} \text { (reactive quenching) }\right) ~=
$$

where A is DPBF in the present case. Since [A] does not change too drastically following a laser pulse, it is possible to derive the following expression to explain the observed bleaching of DPBF

$$
\begin{align*}
& {\left[\mathrm{AO}_{2}\right]_{t=\infty}-\left[\mathrm{AO}_{2}\right]_{t} \simeq} \\
&  \tag{4}\\
& \quad \frac{k_{\mathrm{a}}[\mathrm{~A}]\left[\left[_{1}^{1} \Delta\right]_{t=0}\right.}{1 / \tau+\left(k_{\mathrm{q}}+k_{\mathrm{a}}\right)[\mathrm{A}]} \cdot e^{-\left(11 / \tau+\left(k_{\mathrm{q}}+k_{\mathrm{a}}\right)[\mathrm{A}]\right) t}
\end{align*}
$$

where $\left[\mathrm{AO}_{2}\right]_{t=\infty}$ is the concentration of products after complete decay of ${ }^{\prime} \Delta$ and $\left.{ }^{1} \Delta\right]_{t=0}$ is the concentration produced by the laser pulse. Substituting $\left[\mathrm{AO}_{2}\right]=0$ at $t=0$ and rearranging gives

$$
\begin{equation*}
\left[{ }^{1} \Delta\right]_{t=0}=\left[\mathrm{AO}_{2}\right]_{t=\infty} \frac{1 / \tau+\left(k_{\mathrm{a}}+k_{\mathrm{a}}\right)[\mathrm{A}]}{k_{\mathrm{a}}[\mathrm{~A}]} \tag{5}
\end{equation*}
$$

In an earlier report ${ }^{3}$ we assumed that the observed DPBF quenching constant, ( $k_{\mathrm{q}}+k_{\mathrm{a}}$ ), was approximately equal to $k_{\mathrm{a}}$ itself. Using the measured values of $\tau, k_{\mathrm{a}}$, and $\left[\mathrm{AO}_{2}\right]_{t=\infty}$ in methanol, we calculated that under suitable conditions (see Results, section 3 in ref 3 ) $\left.{ }^{1} \Delta\right]_{t=0}$ was equal to $90 \pm$ $10 \%$ of the concentration of sensitizer (Methylene Blue) triplets produced by a pulse. If, as Matheson and Lee suggest, $k_{\mathrm{a}} \simeq 0.1\left(k_{\mathrm{q}}+k_{\mathrm{a}}\right)$, the quantum efficiency of ${ }^{1} \Delta$ production from Methylene Blue Triplets would have to be $\sim 9.0$. In order not to exceed the generally accepted maximum quantum efficiency of $1.0, k_{\mathrm{q}}$ must in fact be $\$ 0.1 k_{\mathrm{a}}$ justifying our above assumption.

The photolysis data of Adams and Wilkinson also support this conclusion. ${ }^{5}$ Referring to Figure 3 in ref 5, it is evident that essentially all of the initial level of $5 \times 10^{-5} \mathrm{M}$ DPBF is bleached in a single laser pulse. The concentration of ${ }^{1} \Delta$ produced by the pulse cannot exceed $10^{-4} \mathrm{M}$, the concentration of Methylene Blue sensitizer. If nine molecules of ' $\Delta$ were indeed quenched by DPBF for each which reacts, then at most only $1 \times 10^{-5} M$ DPBF could be bleached. This limit is further reduced if competition by solvent quenching is included in the analysis.

Usui has measured quantum yields of photooxidation of DPBF (number of molecules oxidized per photon absorbed by Methylene Blue) in methanol. ${ }^{6}$ Values near unity were obtained at DPBF concentrations as low as $\sim 10^{-4} \mathrm{M}$. Again, if $k_{\mathrm{a}} \simeq 0.1\left(k_{\mathrm{q}}+k_{\mathrm{a}}\right)$, then the quantum yield could never exceed 0.1.

Olmsted and Akashah ${ }^{7}$ have used their quantum efficiency data and our $\tau$ value in methanol (which is accurate regardless of the relative magnitudes of $k_{\mathrm{q}}$ and $k_{\mathrm{a}}$ ) to calculate a value of $k_{\mathrm{a}}$ for DPBF of $6.13 \times 10^{8} \mathrm{M}^{-1} \mathrm{sec}^{-1}$ quite close to our value of $8 \times 10^{8} \mathrm{M}^{-2} \mathrm{sec}^{-1}$. Reactive and physical quenching are unambiguous here as in the other efficiency measurements.

The reason why Matheson and Lee obtain a lower value of $k_{\mathrm{a}}$ is not apparent. Although their data was obtained in Freon 11 rather than methanol, this should not be important since $k_{\mathrm{a}}$ is not very solvent dependent. ${ }^{3}$ Possibly the difficulty lies in their determination of the number of singlet oxygen molecules produced by direct laser excitation. It is interesting to note that the rate constant for quenching of ${ }^{1} \Delta$ by $\beta$-carotene reported by Matheson and Lee is about a factor of 10 less than values obtained by Foote, et al., ${ }^{8}$ Farmilo and Wilkinson, ${ }^{9}$ and ourselves. ${ }^{3}$

## Extrusion of $\mathrm{Fe}_{2} \mathrm{~S}_{2} *$ and $\mathrm{Fe}_{4} \mathrm{~S}_{4} *$ Cores from the Active Sites of Ferredoxin Proteins

Sir:
We have recently demonstrated that polynuclear clear ter complexes of general formulation $\left[\mathrm{Fe}_{4} \mathrm{~S}_{4}(\mathrm{SR})_{4}\right]^{2-1-4}$ and $\left[\mathrm{Fe}_{2} \mathrm{~S}_{2}(\mathrm{SR})_{4}\right]^{2-5}(\mathrm{R}=$ alkyl $)$, which serve as synthetic analogs ${ }^{2,4 \cdots 9}$ of the active sites of oxidized ferredoxin proteins ${ }^{10}\left(\mathrm{Fd}_{\mathrm{ox}}\right)$, undergo facile thiolate substitution reactions. These reactions, effected by the addition of thiols R'SH to solutions of cluster complexes at.ambient temperature, result in the transfer of $\mathrm{Fe}_{4} \mathrm{~S}_{4}{ }^{*}$ and $\mathrm{Fe}_{2} \mathrm{~S}_{2} *$ cores from one ligand environment to another with little or no decomposition and no important changes in core structure. ${ }^{3,5}$ Among these reactions the conversion of $\mathrm{Fe}_{4} \mathrm{~S}_{4}$-glycyl-Lcysteinylglycyl oligopeptide complexes ${ }^{4}$ and $\left[\mathrm{Fe}_{2} \mathrm{~S}_{2}\left(\mathrm{~S}_{2}-\mathrm{O}\right.\right.$ -$\left.\mathrm{xyl}_{2}\right]^{2-5}\left(\mathrm{~S}_{2}-o-\mathrm{xyl}=0\right.$-xylene- $\alpha, \alpha^{\prime}$-dithiolate $)$ with benzenethiol to $\left[\mathrm{Fe}_{4} \mathrm{~S}_{4}(\mathrm{SPh})_{4}\right]^{2-}$ and $\left[\mathrm{Fe}_{2} \dot{\mathrm{~S}}_{2}(\mathrm{SPh})_{4}\right]^{2-}$, respectively, offer clear precedents for the extrusion of core units from holoproteins in the form of their arylthiolate derivatives, reaction 1 , in which the two known types of active sites with $n>11^{10}$ are indicated. From experiments based on previous work, ${ }^{1-4}$ we report here the successful extrusions of

Figure 1. Spectrophotometric demonstration of two extrusion reactions of $8-\mathrm{Fd}_{\mathrm{ox}}$ in $80 \%$ DMSO. Product complexes were identified spectrally.?
the $\mathrm{Fe}_{4} \mathrm{~S}_{4}$ * core of Clostridium pasteurianum ferredoxin ( $8-\mathrm{Fd}_{\mathrm{ox}}$ ) and the $\mathrm{Fe}_{2} \mathrm{~S}_{2}$ * core of the algal protein Spirulina maxima ferredoxin $\left(2-\mathrm{Fd}_{\mathrm{ox}}\right)$. ${ }^{11}$ In complementary and detailed studies Bale and Orme-Johnson ${ }^{12}$ have demonstrated core extrusions from a number of other $\mathrm{Fe}-\mathrm{S}$ proteins.

$$
\begin{array}{r}
n-\mathrm{Fe} \text { (holoprotein) }\left\{\begin{array}{l}
{\left[\mathrm{Fe}_{4} \mathrm{~S}_{4} *(\mathrm{~S}-\mathrm{Cys})_{4}\right]} \\
{\left[\mathrm{Fe}_{2} \mathrm{~S}_{2} *(\mathrm{~S}-\mathrm{Cys})_{4} 7\right.}
\end{array}\right\}+\mathrm{R}^{\prime} \mathrm{SH} \longrightarrow \\
{\left[\mathrm{Fe}_{4} \mathrm{~S}_{4}\left(\mathrm{SR}^{\prime}\right)_{4}\right]^{2-} \text { and } / \text { or }\left[\mathrm{Fe}_{2} \mathrm{~S}_{2}\left(\mathrm{SR}^{\prime}\right)_{4}\right]^{2-}} \tag{1}
\end{array}
$$

The utility of various thiols in extrusion reactions, which were monitored spectrophotometrically (Figures 1 and 2), has been examined; experimental conditions and results are given in Table I. In the $80 \%$ DMSO reaction medium employed the proteins are expected to be unfolded to a considerable extent, ${ }^{13,14}$ thereby allowing easier access of the thiol to the active site at which, extrapolating from kinetic studies of synthetic complexes, ${ }^{15}$ protonation of coordinated S Cys by R'SH initiates the substitution process. The shift of the visible band in the $8-\mathrm{Fd}_{\mathrm{ox}}$ spectrum from 390 nm in aqueous solution to 410 nm in $80 \%$ DMSO places it in the range of $\mathrm{Fe}_{4} \mathrm{~S}_{4}$-peptide complexes in this solvent (404-409 nm ), indicating significant denaturation. ${ }^{4}$ Treatment of this protein with excess benzenethiol affords clean extrusion of the active site core in the form of thoroughly characterized $\left[\mathrm{Fe}_{4} \mathrm{~S}_{4}(\mathrm{SPh})_{4}\right]^{2-,},{ }^{2,3,7}$ readily distinguished from the protein by its band at $458 \mathrm{~nm}^{2}$ (Figure 1). Similarly, reaction of 2 $\mathrm{Fd}_{0 \times}$ with benzenethiol and $o-\mathrm{xyl}(\mathrm{SH})_{2}$ leads to extrusion of the $\mathrm{Fe}_{2} \mathrm{~S}_{2}{ }^{*}$ core as its $\left[\mathrm{Fe}_{2} \mathrm{~S}_{2}(\mathrm{SPh})_{4}\right]^{2-}$ and $\left[\mathrm{Fe}_{2} \mathrm{~S}_{2}\left(\mathrm{~S}_{2}-\mathrm{O}-\right.\right.$ $\left.\mathrm{xyl})_{2}\right]^{2-}$ derivatives, respectively, whose spectra (Figure 2)
