# The Chemical Bond in Phosphoranes. Comparative ab Initio Study of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and the Hypothetical Molecules $\mathrm{NH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{5}$ 

Frerich Keil ${ }^{1 \mathbf{a}}$ and Werner Kutzelnigg*1b<br>Contribution from the Institut für Physikalische Chemie und Elektrochemie der Universität, Karlsruhe, D-7500 Karlsruhe, Germany, and Lehrstuhl für Theoretische Chemie der Ruhr Universität Bochum, D-4630 Bochum. Germany. Received September 9, 1974

#### Abstract

Ab initio SCF calculations are performed for the molecules $\mathrm{NH}_{3}, \mathrm{NH}_{2} \mathrm{~F}, \mathrm{NH}_{3} \mathrm{~F}^{+}, \mathrm{NH}_{3} \mathrm{~F}_{2}, \mathrm{PH}_{3}, \mathrm{PH}_{2} \mathrm{~F}, \mathrm{PH}_{3} \mathrm{~F}_{2}$ (four isomers), $\mathrm{PH}_{5}, \mathrm{PH}_{4} \mathrm{~F}, \mathrm{PH}_{2} \mathrm{~F}_{3}$ with different gaussian basis sets, with and without d functions on $\mathrm{P}, \mathrm{N}$, and $\mathrm{F} . \mathrm{NH}_{3} \mathrm{~F}_{2}$ is not stable with respect to $\mathrm{NH}_{2} \mathrm{~F}+\mathrm{HF}$ or the ion pair $\mathrm{NH}_{3} \mathrm{~F}^{+} \mathrm{F}^{-}$but probably is lower in energy than $\mathrm{NH}_{3}+2 \mathrm{~F}$ or $\mathrm{NH}_{3}+$ $\mathrm{F}_{2} . \mathrm{PH}_{3} \mathrm{~F}_{2}$ is at least $170 \mathrm{kcal} / \mathrm{mol}$ below $\mathrm{PH}_{3}$ (planar) +2 F and by $\sim 40 \mathrm{kcal} / \mathrm{mol}$ with respect to $\mathrm{PH}_{2} \mathrm{~F}+\mathrm{HF}$. The energy lowering due to $\mathrm{d} A \mathrm{AO}$ 's on P is $\sim 40 \mathrm{kcal} / \mathrm{mol}$ both in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{5}$. The role of d AO's both for the energy and the population analysis is compared for $\mathrm{NH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{3} \mathrm{~F}_{2}$. Four isomers of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ are compared. In $\mathrm{PH}_{5}$ correlation effects are accounted for as well. Conclusions are drawn as to the mechanism of the three-center four-electron bond and bonding in phosphoranes

## 1. Introduction

Molecules with pentacoordinated phosphorus are very interesting from the point of view of valence theory and have therefore been the object of several quantum chemical studies in the past few years (for rather up-to-date compilations see ref 2). Most of these studies were devoted either to the hypothetical molecule $\mathrm{PH}_{5}{ }^{2 \mathrm{~b}, 3}$ or to the well-known species $\mathrm{PF}_{5}{ }^{2 \mathrm{a}, 4,5}$ For either compound both semiempirical ${ }^{2 \mathrm{~b}, 4,5}$ and ab initio ${ }^{1,3}$ calculations have been published. In the most sophisticated paper on $\mathrm{PF}_{5}$ by Strich and Veillard ${ }^{2 a}$ some calculations on other phosphoranes, in particular $\mathrm{PF}_{4} \mathrm{H}$, $\mathrm{PF}_{3} \mathrm{H}_{2}$, and $\mathrm{PFH}_{4}$, are mentioned, not however on $\mathrm{PH}_{3} \mathrm{~F}_{2}$, a molecule that has only recently been synthesized. ${ }^{6}$

In our opinion $\mathrm{PH}_{3} \mathrm{~F}_{2}$ (that also represents $\mathrm{PR}_{3} \mathrm{~F}_{2}$ ) is not only the simplest and most clear-cut example of a compound of "pentavalent" phosphorus but it also provides a prototype of a three-center four-electron bond like it occurs, e.g., in $\mathrm{XeF}_{2}$. A careful analysis of the electron structure of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ may therefore (complementary to the study of the somewhat different molecule $\mathrm{PF}_{5}$ ) serve to give insight into the mechanism of electron-rich chemical bonds.

As is well known two opposite views have been proposed to look at bonding in pentavalent phosphorus compounds (for historical reviews see ref 7 and 8 ): (a) one assumes $\mathrm{sp}^{3} \mathrm{~d}$ hybridization ${ }^{9}$ at the P atom which leads to five covalent, though nonequivalent, bonds (three of them involve $\mathrm{sp}^{2}$ hybrids on P , two of them pd hybrids); (b) one explains bonding without involving d AO's, through a three-center fourelectron axial FPF bond, the three equatorial PH bonds being ordinary two-center two-electron bonds. ${ }^{10}$

We want to answer the following questions. 1. Which role do the d AO's of phosphorus play for bonding in pentavalent phosphorus compounds? Are they as important for $\mathrm{PH}_{3} \mathrm{~F}_{3}$ as for $\mathrm{PF}_{5}$ ? 2. How important is the particular value of the lowest ionization potential of P (or rather planar $\mathrm{PH}_{3}$ ) for making $\mathrm{PH}_{3} \mathrm{~F}_{2}$ a stable molecule? 3. How important is the electronegativity of the axial ligands ( F in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ ) for making the three-center four-electron bond stable? 4. How important is back-bonding? 5. Why are there no compounds of "pentavalent" nitrogen?

To answer question 1 we have performed computations both with and without $d$ functions in the AO basis. Question 2 is somewhat suggested by Pitzer's ${ }^{11}$ correlation between stability of noble gas fluorides and the respective ionization potentials. To answer this question we have com-
pared $\mathrm{PH}_{3} \mathrm{~F}_{2}$ with the hypothetical molecule $\mathrm{NH}_{3} \mathrm{~F}_{2}$. A comparison of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{5}$ served to study the role of the axial ligands and gives some information about the role of back-bonding. We have not performed calculations on $\mathrm{PF}_{5}$ but our basis sets are sufficiently close to those of Strich and Veillard ${ }^{2 a}$ that their values can serve for reference to document differences between $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PF}_{5}$.

The energy differences between different isomers of $\mathrm{PH}_{2} \mathrm{~F}_{3}$ and $\mathrm{PF}_{5}$ are directly related to the ease of isomerization by a pseudorotation ${ }^{12}$ (or turnstile ${ }^{13}$ ) mechanism. In $\mathrm{PH}_{3} \mathrm{~F}_{2}$, the equilibrium structure of which has most likely $D_{3 h}$ symmetry, the F atoms are equivalent and so are the H atoms. Isomerization can hence be studied less easily experimentally, since it does not lead to a scrambling of previously nonequivalent positions. We think that the energy differences between the isomers of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ deserve some interest nevertheless.

## 2. Choice of the Computation Method and the Basis Sets

The majority of the calculations reported here are of SCF type with basis sets of gaussian lobes. We went beyond the SCF approximation and calculated the correlation energy as well only for $\mathrm{PH}_{5}$, using the IEPA-PNO, PNO-CI, and CEPA-PNO methods, respectively. ${ }^{14-17}$ The reliability of the SCF approximation for the questions that we want to answer is discussed in sections 6 and 12 . Here we point out that a comment on the change of the correlation energy is needed whenever we consider breaking of bonds (e.g., the energy difference between $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{3}+2 \mathrm{~F}$ ) but that we can rely on the change in correlation energy to be insignificant for dissociation of one closed shell molecule into two closed shell molecules (e.g., $\mathrm{PH}_{3} \mathrm{~F}_{2} \rightarrow \mathrm{PH}_{3}+\mathrm{F}_{2} \rightarrow$ $\mathrm{PH}_{2} \mathrm{~F}+\mathrm{HF}$ ). Also equilibrium distances are usually rather well predicted by SCF calculations.

The basis sets were chosen as the smallest ones that are able to account for the effects that we want to study. The pilot calculations on smaller molecules described in section 3 led us to the following "standard" basis sets for the larger systems.

Hydrogen: a 4s Huzinaga basis ${ }^{18}$ in the contraction ( 3,1 ), augmented by a p function (in all three directions) with $\eta=$ 0.65. In some cases the $p$ functions are omitted; this is then explicitly mentioned. For the axial hydrogens in $\mathrm{PH}_{5}$ we used an additional s lobe with $\eta=0.03$.

Nitrogen: ( $7 \mathrm{~s} / 4 \mathrm{p}$ ) in the contraction (3,1,1,1,1/2,1,1).

Table I. Total and Atomization Energies (au) of $\mathrm{NH}_{3}$ (planar) for Different N Basis Sets

| Basis | $-E_{\text {tot }}$ | $-E_{\text {bind }}$ |
| :---: | :---: | :---: |
| (7.4), no p on H | 56.1404 | 0.2692 |
| Std $=(7,4$, with p on H | 56.1694 | 0.2982 |
| $+\mathrm{d}^{2}$ ( $\mathrm{d} \sigma$ ) | 56.1695 | 0.2983 |
| $+\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}(\mathrm{~d} \delta)$ | 56.1714 | 0.3002 |
| $+\mathrm{d}_{z^{2}}+\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}$ | 56.1715 | 0.3003 |
| (9.5), with p on H | 56.1936 | 0.3014 |
| $+\mathrm{d}_{z}{ }^{2}(\mathrm{~d} \sigma)$ | 56.1937 | 0.3015 |
| $+\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}(\mathrm{~d} \delta)$ | 56.1956 | 0.3034 |
| $+\mathrm{d}_{z^{2}}+\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}$ | 56.1958 | 0.3036 |
| Ref 19 | 56.2138 | 0.3132 |
| Ref 21. SCF | 56.2072 |  |
| With valence shell correlation | 56.4318 |  |
| Exptl (ref 20) | 56.5818 | 0.4606 |

We also used this standard basis plus a d set with $\eta=1.0$ (or, if indicated, $\eta=0.9$ ).

Fluorine: ( $7 \mathrm{~s} / 3 \mathrm{p}$ ) in the contraction ( $3,1,1,1,1 / 2,1$ ) but with the exponents of the $p$ AO's scaled by a factor 1.15 and augmented by a "diffuse" $p$ function with $\eta=0.1173$, both the scaling factor and the additional function being optimized for $\mathrm{F}^{-}$. In some calculations this standard basis plus $\mathrm{d}_{z^{2}}, \mathrm{~d}_{x z}$, and $d_{y z}$ functions with $\eta=0.5$ were used.

Phosphorus: $(10 s / 6 p)$ in the contraction $(4,6 \times 1 /$ $3,1,1,1$ ). Another basis for $P$ is identical with this standard basis but contains a set of d AO's as well. The exponents were optimized individually in different cases. For $\mathrm{PH}_{3} \mathrm{~F}_{2}$ different exponents for $\mathrm{d}_{z^{2}} / \mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ on one side and $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ on the other side were allowed for (the fluorines being on the $z$ axis). In some calculations a single exponent $\eta=0.57$ was chosen for all the five d components. For $\mathrm{NH}_{3}, \mathrm{PH}_{3}$, and HF larger basis sets were used as well. They are indicated explicitly when they come up.

## 3. Study of $\mathrm{NH}_{3}, \mathrm{PH}_{3}, \mathrm{HF}$, and F

Planar $\mathrm{NH}_{3}$ and $\mathrm{PH}_{3}$ had to be studied since we want to know the binding energy of $\mathrm{NH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{3} \mathrm{~F}_{2}$ with respect to $\mathrm{NH}_{3}+2 \mathrm{~F}$ and $\mathrm{PH}_{3}+2 \mathrm{~F}$. The molecules $\mathrm{NH}_{3}$ and $\mathrm{PH}_{3}$ also served for testing the basis sets. Several calculations on planar $\mathrm{NH}_{3}$ are compared in Table I. Although the total energy depends very strongly on the basis size the binding energy (with respect to $\mathrm{N}+3 \mathrm{H}$ ) of 0.2982 au obtained with the standard basis differs by $1 \%$ from that from a $(9,5)$ basis or by $2 \%$ from that from a $(9,5)$ basis with a d set.

The value of Rauk et al. ${ }^{19}$ of 0.3132 au obtained with a very large basis, which is close to the Hartree-Fock limit, is only "better" by $6 \%$ than our standard value. The experimental value is $0.4540 \mathrm{au}^{20}$ and the correlation error is much larger than the distance of our value to the HartreeFock limit.

We note that inclusion of d AO's on N to the standard basis improves the binding energy of $\mathrm{NH}_{3}$ by 0.0019 au as far as $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ is concerned and by 0.0001 au for $\mathrm{d}_{z^{2}}$. For symmetry reasons $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ do not contribute. One knows that $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ are important if one wants to account correctly for the inversion barrier of $\mathrm{NH}_{3}$, but such small energy contributions (a few kilocalories per mole) are not relevant in the present context. For the standard basis calculations of planar $\mathrm{NH}_{3}$ the geometry was optimized. An NH distance of $1.873 a_{0}$ was found without d AO's on N and $1.870 a_{0}$ with d AO's. The respective force constant for the pulsation vibration was found to be 25.27 and 26.21 mdyn/ $\AA$. The estimated exact values are $1.880 a_{0}$ and 24.7 $\operatorname{mdyn} / \AA .{ }^{21}$

In the case of planar $\mathrm{PH}_{3}$ (see Table II) the energy improvements due to d AO's are roughly an order of magnitude larger than in $\mathrm{NH}_{3}$, namely 0.0120 for $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$

Table II. Total and Atomization Energies (au) of $\mathrm{PH}_{3}$ (planar) for Different $P$ Basis Sets

| Basis | $-E_{\text {tot }}$ | $-E_{\text {bind }}$ |
| :---: | :---: | :---: |
| $(9,5)$, with p on H | -342.1673 | 0.1731 |

| $+\mathrm{d}_{z^{2}}+\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}$ | -342.3322 | 0.2083 |
| $(12,9)$, with p on H | -342.3958 | 0.1982 |
| $+\mathrm{d}^{2}$ | -342.3969 | 0.1993 |
| $+\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}$ | -342.4085 | 0.2109 |
| $+\mathrm{d}_{z^{2}}+\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}$ | -342.4089 | 0.2122 |
| Ref 22 | -342.3974 | 0.2072 |
| Ref 23, SCF | -342.4503 | 0.2121 |
| With valence shell correlation | -342.6217 |  |
| Exptl (using data of ref 22) | -343.857 | 0.332 |

and 0.0012 au for $\mathrm{d}_{z^{2}}$. These values are almost independent on whether one starts from $(9,5),(10,6)$, or $(12,9)$ basis. The binding energy obtained with the standard basis, with and without d AO's, is -0.1957 and -0.2083 au , to be compared with the best published value of Lehn and Munsch ${ }^{22}$ of -0.2072 au . With a very large basis (two $d$ and one $f$ sets on P ) we recently got a Hartree-Fock binding energy of $0.2121 \mathrm{au} .{ }^{23}$ For the PH distance and the force constant we find $2.58 a_{0}$ (with d) ( $2.62 a_{0}$ in ref 22 ) and $13.84 \mathrm{mdyn} / \AA$. The optimum exponent for the d AO's is $\eta=0.925$. If one uses $\eta=1$ (which we did) the energy is raised by roughly 0.0001 au. Since the F atoms in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ carry large negative charges and since we are also going to study ionic species like $\mathrm{NH}_{3} \mathrm{~F}^{+}-\mathrm{F}^{-}$our F basis must be equally appropriate for F and $\mathrm{F}^{-}$. None of the smaller Huzinaga basis sets has this property. With the $(7,3)$ basis the energy of $F^{-}$is 0.0051 au above the ground state energy of $F$ whereas calculations at the Hartree-Fock limit ${ }^{24}$ yield $\mathrm{F}^{-} 0.0501$ au below F (with correlation this difference in the electron affinity is even $0.13 \mathrm{au}) .{ }^{25}$ The basis is obviously too poor for $\mathrm{F}^{-}$. The $(9,5)$ basis gives $\mathrm{F}^{-}$more stable by 0.0222 than F , but it is much more effective to use the $(7,3)$ basis with an additional "diffuse" p lobe of $\eta=0.1$ which yields $\mathrm{F}^{-}$more stable than F by 0.0502 au . With this basis set the energies of F and $\mathrm{F}^{-}$ are -99.2591 and -99.3093 au , respectively. Optimizing the scaling factor for the p AO's and the orbital exponent of the additional p function for $\mathrm{F}^{-}$, which leads to our standard basis, lowers these values to -99.2682 and -99.3199 but changes the electron affinity of $F$ only to 0.0513 . We also used calculations on HF to check the quality of our basis. With the standard basis we get a binding energy of 0.1416 au which is improved by inclusion of d AO's on $F$ to 0.1487 au ; the $(9,5)$ basis gives 0.1450 and 0.1501 au with d AO's on F. The best Hartree-Fock and "exact" values are $0.1611^{26}$ and 0.225 au, ${ }^{27}$ respectively.

We conclude that our standard basis sets are "well balanced", in particular that no spurious d AO contributions result from s or $p$ unsaturations of the basis.

## 4. The Hypothetical $\mathrm{NH}_{3} \mathrm{~F}_{2}$

The computed energies to which we refer in this and the following section are collected in Table III.
$\mathrm{NH}_{3} \mathrm{~F}_{2}$ has not been observed experimentally. We first assumed that it has the structure of a trigonal bipyramid with the F atoms as axial ligands. The NH distance was kept fixed at its value for planar $\mathrm{NH}_{3}\left(1.87 a_{0}=0.99 \AA\right)$ and the equilibrium NF distance was obtained as $3.22 a_{0}$ $(1.70 \AA)$ irrespective of d AO's on nitrogen. In the standard

basis without d AO's on N the total energy is $\mathbf{- 2 5 4 . 6 7 8 0}$, i.e., $0.0287 \mathrm{au}(18 \mathrm{kcal} / \mathrm{mol})$ above the sum of the energies of $\mathrm{NH}_{3}$ (planar) +2 F in the same basis. (In a calculation without p AO's on H the total energy is -254.6386 au which is 0.0390 above the corresponding sum for $\mathrm{NH}_{3}+$ 2 F . This indicates that the p AO's on hydrogen stabilize $\mathrm{NH}_{3} \mathrm{~F}_{2}$ with respect to $\mathrm{NH}_{3}+2 \mathrm{~F}$ by about 0.01 au ). The standard basis with d AO's gives a total energy of -254.6888 , which is 0.0179 au ( $11 \mathrm{kcal} / \mathrm{mol}$ ) above that of $\mathrm{NH}_{3}$ (planar) +2 F . Inclusion of just $\mathrm{d}_{2} 2$ lowers the (total) energy of $\mathrm{NH}_{3} \mathrm{~F}_{2}$ by 0.0076 au and of $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ by 0.0021 au , whereas the three functions together lower the energy by 0.0087 au and the full d set by $0.0108 \mathrm{au}(7 \mathrm{kcal} / \mathrm{mol})$. Inclusion of a d set on F lowers the energy further by $\sim$ $0.02 \mathrm{au}(12.5 \mathrm{kcal} / \mathrm{mol})$ to -254.7069 au , so that is practically equal in energy with planar $\mathrm{NH}_{3}+2 \mathrm{~F}$. We are pretty sure that with electron correlation $\mathrm{NH}_{3} \mathrm{~F}_{2}$ in $D_{3 h}$ geometry will turn out to be significantly lower in energy than planar $\mathrm{NH}_{3}+2 \mathrm{~F}$, and even lower than pyramidal $\mathrm{NH}_{3}+2 \mathrm{~F}$ (since $\mathrm{NH}_{3}$ (planar) and $\mathrm{NH}_{3}$ (pyramidal) differ by only 6 $\mathrm{kcal} / \mathrm{mol}$ ). For the isoelectronic ion $\mathrm{CH}_{3} \mathrm{~F}_{2}^{-}$Dedieu and Veillard ${ }^{28}$ have found that the $D_{3 h}$ structure is not a minimum but rather a saddle point of the potential hypersurface and that $\mathrm{CH}_{3} \mathrm{~F}_{2}{ }^{-}$is stabilized by a distortion to $C_{3 v}$ symmetry (see Figure 1).

We therefore investigated whether $\mathrm{NH}_{3} \mathrm{~F}_{2}$ is stable with respect to a distortion to $C_{3 v}$ symmetry and found that it is

I

II

Figure 1. Optimum $C_{3 v}$ structure of $\mathrm{NH}_{3} \mathrm{~F}$, calculated without (1) and with (II) polarization functions on N and H .
not. We studied this deformation both with the standard basis without p AO's on H (I) and with the standard basis including a d set on N (II). The geometries that one obtains on imposing $C_{3 v}$ symmetry are shown in Figure 1 for both basis sets. Without p AO's on H and d AO's on N the energy lowering due to this deformation is 0.0174 au and with polarization functions it is $0.0204 \mathrm{au}(13 \mathrm{kcal} / \mathrm{mol})$. One sees from the geometry in Figure 1 and the population analysis in Table IV that the $C_{3 v}$ structure of $\mathrm{NH}_{3} \mathrm{~F}_{2}$ is actually an ion pair $\mathrm{NH}_{3} \mathrm{~F}^{+}-\mathrm{F}^{-}$held together by the Coulomb attraction. The sum of the energies of isolated $\mathrm{NH}_{3} \mathrm{~F}^{+}$and $\mathrm{F}^{-}$ ions in the standard basis without d on H is $\mathbf{- 2 5 4 . 4 1 6 4}$ which is $\sim 0.24$ au above the energy of the ion pair.

We did not inquire whether the $C_{3 v}$ structure is a real local minimum of the potential hypersurface, but we are sure that it cannot be the absolute minimum, since the sum of the energies of $\mathrm{NH}_{2} \mathrm{~F}+\mathrm{HF}$ turns out to be lower than that of $\mathrm{NH}_{3} \mathrm{~F}_{2}\left(C_{3 v}\right)$ by 0.039 au ( $25 \mathrm{kcal} / \mathrm{mol}$, standard basis, without p on H ). In the calculation of $\mathrm{NH}_{2} \mathrm{~F}$ tetrahedral angles were assumed and the NH distance was taken the same as in $\mathrm{NH}_{3}$ (pyramidal, $r=1.89 a_{0}=1.00 \AA$ ). The NF distance was optimized and found to be $2.689 a_{0}$ ( $=$ $1.43 \AA$ ). While $\mathrm{NH}_{3} \mathrm{~F}_{2}$ turns out to be unstable with respect to $\mathrm{NH}_{2} \mathrm{~F}+\mathrm{HF}$ we find it stable with respect to $\mathrm{NH}_{3}+\mathrm{F}_{2}$. In the standard basis without p on $\mathrm{H} \mathrm{NH}_{3} \mathrm{~F}_{2}\left(C_{3 \nu}\right)$ is lower in energy than $\mathrm{NH}_{3}$ (planar) $+\mathrm{F}_{2}$ by 28 kcal and in the standard basis with d on N by $42 \mathrm{kcal} / \mathrm{mol}$. (The values referring to pyramidal $\mathrm{NH}_{3}$ are 22 and $36 \mathrm{kcal} / \mathrm{mol}$, respectively.) One has to remember that in the Hartree-Fock approximation $F_{2}$ is not bound with respect to 2 F , because the correlation energy contribution to the binding energy of $\mathrm{F}_{2}$ is as large as $80 \mathrm{kcal} / \mathrm{mol}$ (for comparison $\mathrm{H}_{2}: \sim 25 \mathrm{kcal} /$ $\mathrm{mol}, \mathrm{HF} \sim 40 \mathrm{kcal} / \mathrm{mol}$ ). If we assume that the correlation contribution for either of the two NF bonds is as large as that of a HF bond, the correlation contributions to the reaction $\mathrm{NH}_{3}+\mathrm{F}_{2} \rightarrow \mathrm{NH}_{3} \mathrm{~F}_{2}$ should nearly cancel, so that we can in fact expect $\mathrm{NH}_{3} \mathrm{~F}_{2}$ to be more stable than $\mathrm{NH}_{3}+\mathrm{F}_{2}$ (and also with respect to $\mathrm{NH}_{3}+2 \mathrm{~F}$ ). For $\mathrm{F}_{2}$ we have optimized the FF distance for our basis (see Table III).

## 5. $\mathrm{PH}_{3} \mathrm{~F}_{2}$

$\mathrm{PH}_{3} \mathrm{~F}_{2}$ was synthetized by Seel and Velleman. ${ }^{6}$ It readily disproportionates to $\mathrm{PH}_{2} \mathrm{~F}_{3}+\mathrm{PH}_{3}+\mathrm{HF}$ but is stable enough to be characterized by its ir spectrum. The exact geometry of this molecule is not known, although there is no doubt that it is a trigonal bipyramid with the F atoms as axial ligands. We computed the energy of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ for such a structure first without d AO's on P, taking the PH distances the same as in planar $\mathrm{PH}_{3}\left(2.58 a_{0}=1.36 \AA\right)$ and optimizing the PF distance, which resulted in $3.306 a_{0}(1.75 \AA$ ).

The total energy (standard basis without d) was -541.0211 au which corresponds to a binding energy of -0.1643 au ( $103 \mathrm{kcal} /$ mole) with respect to $\mathrm{PH}_{3}$ (planar) and 2 F (without p AO's on H the total energy is 540.9648 au , and the binding energy is 0.1480 au as for $\mathrm{NH}_{3} \mathrm{~F}_{2}$ these p AO's stabilized $\mathrm{PH}_{3} \mathrm{~F}_{2}$ with respect to $\mathrm{PH}_{3}+2 \mathrm{~F}$ by about 0.01 au ). Subsequent optimization of the PH distance yielded $2.63 a_{0}$; this value was however reduced to nearly $2.58 a_{0}$ when d AO's on P were included in the basis. We therefore used $2.58 a_{0}$ for all calculations. For the calculations with d AO's the exponents of the nonequivalent $d$ functions were optimized individually and the best values were found to be

$$
\begin{gathered}
\eta=0.925 \text { for } \mathrm{d}_{x y} \text { and } \mathrm{d}_{x^{2}-y^{2}} \\
\eta=0.5 \text { for } \mathrm{d}_{z^{2},} \mathrm{~d}_{x z} \text { and } \mathrm{d}_{y z}
\end{gathered}
$$

The difference in the exponents comes from the different role of the respective d functions: $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ contribute to the PH bonds, $\mathrm{d}_{z^{2}}$ to the PF $\sigma$ bond, and $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ to the PF $\pi$ bond ("back-bonding"). One finds that the energy improvement due to $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ is about the same as in $\mathrm{PH}_{3}$ so that they do not influence the binding energy much.

Inclusion of the d AO's to the basis reduces the PF distance from $3.306 a_{0}(1.75 \AA)$ to $3.185 a_{0}(1.68 \AA)$. The binding energy which was -0.1643 au without $d$ AO's is -0.2258 au when $\mathrm{d}_{z^{2}}, \mathrm{~d}_{x z}$, and $\mathrm{d}_{y z}$ are included. The improvement of the binding energy by $\mathrm{d}_{2} 2$ is 0.0408 au , that by $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z} 0.0225 \mathrm{au}$, and that of the three together $0.0615 \mathrm{au}(40 \mathrm{kcal} / \mathrm{mol})$. An additional lowering of the energy is achieved by the inclusion of $\mathrm{d}_{x z} \mathrm{~d}_{y z,}$ and $\mathrm{d}_{z^{2}}$ polarization functions with $\eta=0.5$ on F . A calculation that included these $d$ AO's on $F$ in addition to the full $d$ set on $P$

III

II

Figure 2. Geometries of four isomers of $\mathrm{PH}_{3} \mathrm{~F}_{2}$.
led to a total energy of 541.1394 au and a binding energy of -0.2700 au ( $170 \mathrm{kcal} / \mathrm{mol}$ )
$\mathrm{PH}_{3} \mathrm{~F}_{2}$ is, unlike $\mathrm{NH}_{3} \mathrm{~F}_{2}$, quite strongly bound with respect to $\mathrm{PH}_{3}+2 \mathrm{~F} ; \mathrm{PH}_{3} \mathrm{~F}_{2}$ would be stable even without any contributions of d AO's on P. The contribution of $40 \mathrm{kcal} /$ mol due to the d AO's is surely not negligible but is not large compared to the $103 \mathrm{kcal} / \mathrm{mol}$ from the calculation without d AO's and the $25 \mathrm{kcal} / \mathrm{mol}$ contribution of the d AO's on $F$.

One may be worried about the rather large contribution of the d AO's on F. However, the d AO's on F contribute about as much to the binding energy of $F_{2}$. The $d$ AO's on $F$ do not therefore affect the binding energy of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ with respect to $\mathrm{PH}_{3}$ (planar) $+\mathrm{F}_{2}$ to an appreciable extent, whereas the $\mathrm{d} A O$ 's on P contribute to the binding energy with respect to $\mathrm{PH}_{3}+\mathrm{F}_{2}$ as much as to that with respect to $\mathrm{PH}_{3}+2 \mathrm{~F}$. Since a single d set on P lowers the energy of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ by as much as $40 \mathrm{kcal} / \mathrm{mol}$ one can estimate that a second $d$ set and an $f$ set may lead to an additional lowering of the order of magnitude of $10 \mathrm{kcal} / \mathrm{mol}$, so that the real SCF binding energy is somewhat larger than the computed one.
$\mathrm{PH}_{3} \mathrm{~F}_{2}$ is, unlike $\mathrm{NH}_{3} \mathrm{~F}_{2}$, quite stable with respect to dissociation into $\mathrm{PH}_{2} \mathrm{~F}+\mathrm{HF}$. A calculation without pAO 's on H and without d AO's on P yields $\mathrm{PH}_{3} \mathrm{~F}_{2} 0.0074 \mathrm{au}$ ( $5 \mathrm{kcal} /$ mol) lower than $\mathrm{PH}_{2} \mathrm{~F}+\mathrm{HF}$, whereas with p AO's on H and d AO's on $P$ this difference is $0.0622 \mathrm{au}(40 \mathrm{kcal} / \mathrm{mol})$. One sees that the d AO's are quite decisive as far as the stability of $\mathrm{PH}_{3} \mathrm{~F}_{2}$. with respect to $\mathrm{PH}_{3} \mathrm{~F}+\mathrm{HF}$ is concerned, whereas they do not matter for the respective stability of $\mathrm{NH}_{3} \mathrm{~F}_{2}$.

For the calculation of $\mathrm{PH}_{2} \mathrm{~F}$ we assumed that all the angles are tetrahedral and that $r(\mathrm{PH})$ is the same as in $\mathrm{PH}_{3}$ (pyramidal equilibrium configuration). The PF distance was optimized to yield $r(\mathrm{PF})=3.17 a_{0}$.

We studied three more isomers of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ (see Figure 2). For consistency's sake we used a single exponent ( $\eta=0.57$, cf. ref 2a) for the d AO's on P. In structure II, a trigonal bipyramid with one axial and one equatorial $F$, we used $r\left(\mathrm{PF}_{\mathrm{ax}}\right)=3.185 a_{0}$ and $r\left(\mathrm{PH}_{\mathrm{eq}}\right)=2.58 a_{0}$ as in structure $\mathrm{I}\left(D_{3 h}\right), r\left(\mathrm{PF}_{\mathrm{eq}}\right)=3.08 a_{0}$ from our optimization for $\mathrm{PH}_{4} \mathrm{~F}$, and $r\left(\mathrm{PH}_{\mathrm{ax}}\right)=2.806 a_{0}$ from $\mathrm{PH}_{5}$. The same values were used in structure III, a trigonal bipyramid with two equatorial F bonds. Structure IV is a square pyramid with the two

F's at diagonal positions. The HPF and HPH angles were taken as 101.34 and $103.95^{\circ}$ from ref 2a and 3, respectively. For $r\left(\mathrm{PH}_{\mathrm{ap}}\right)$ we choose the same value as for $r\left(\mathrm{PH}_{\mathrm{eq}}\right)=$ $2.58 a_{0} ; r\left(\mathrm{PH}_{\mathrm{bas}}\right)=2.693 a_{0}$ and $r\left(\mathrm{PF}_{\mathrm{bas}}\right)=3.133 a_{0}$ were chosen as the mean values of the respective equatorial and axial distances.

The energies of the four isomers are given in Table III. One sees that structure $\mathrm{I}\left(D_{3 h}\right)$ has the lowest energy of the four isomers. Structure IV is the only one that is somewhat competitive. It is, however, unlikely that structure IV represents a local minimum; there is probably a monotonic increase in energy in going from structure I via structure IV and II to structure III. Other square pyramidal structures are supposed to be much higher in energy. ${ }^{3}$

Since $\mathrm{NH}_{3} \mathrm{~F}_{2}$ is stabilized by a deformation from the $D_{3 h}$ to a $C_{3 v}$ structure we checked whether $\mathrm{PH}_{3} \mathrm{~F}_{2}$ (structure I) is stable with respect to the same kind of deformation. An out-of-plane displacement of the $P$ atom by $0.2 a_{0}(\approx 6 \%$ of the PF bond length) led to an increase of the energy from -541.1394 to -541.1317 au . We conclude that structure I represents in fact the equilibrium geometry. To state this with absolute certainty would require a few more calculations.

## 6. The Hypothetical $\mathrm{PH}_{5}$

$\mathrm{PH}_{5}$ has been studied previously by several authors ${ }^{2 \mathrm{~b}, 3}$ mainly as a simple model for $\mathrm{PF}_{5}$. We are interested in the questions whether $\mathrm{PH}_{5}$ is stable with respect to $\mathrm{PH}_{3}+2 \mathrm{H}$ and whether it is stable with respect to a deformation from $D_{3 h}$ to $C_{3 v}$ symmetry, and in similarities and differences between $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{5}$.

For all calculations of $\mathrm{PH}_{5}$ we used the standard basis including d AO's on P with $\eta=0.925$ for $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ and $\eta$ $=0.5$ for $\mathrm{d}_{z^{2}}, \mathrm{~d}_{x z}$, and $\mathrm{d}_{y z}$, but in addition the basis sets of the axial H atoms were augmented by a diffuse s lobe with $\eta=0.03$ (that is appropriate for $\mathrm{H}^{-}$) since these atoms were expected to carry an appreciable negative charge.

For $\mathrm{PH}_{5}$ not only SCF calculations but also calculations that account for electron correlation were performed. The IEPA-PNO, ${ }^{14}$ CEPA-PNO, ${ }^{15}$ and $\mathrm{PNO}-\mathrm{CI}^{16}$ methods are described in detail elsewhere. ${ }^{17}$ We have used a localized representation.

Assuming $D_{3 h}$ geometry and taking $r\left(\mathrm{PH}_{\mathrm{eq}}\right)=2.58 a_{0}$ as in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ the equilibrium value $r\left(\mathrm{P}-\mathrm{H}_{\mathrm{ax}}\right)=2.806 a_{0}$ was found.

The total energies on the SCF levels including valence shell electron correlation in the IEPA-PNO, PNO-CI, and CEPA-PNO levels are

$$
\begin{gathered}
E_{\mathrm{SCF}}=-343.4573 \mathrm{au} \\
E_{1 \mathrm{EPA}}=-343.6694 \mathrm{au} \\
E_{\mathrm{CEPA}}=-343.6529 \mathrm{au} \\
E_{\mathrm{C} 1}=-343.6388 \mathrm{au}
\end{gathered}
$$

the respective values for $\mathrm{PH}_{3}$ (planar), $\mathrm{H}_{2}$, and their sum are: $\left(E_{\mathrm{SCF}}\right)-342.3960,1.1286,343.5246 \mathrm{au} ;\left(E_{\text {IEPA }}\right)$ $-342.5653,1.1625,343.7278 \mathrm{au} ;\left(E_{\mathrm{CEPA}}\right)-342.5512$, $1.1625,343.7137 \mathrm{au} ;\left(\mathrm{E}_{\mathrm{CI}}\right)-342.5414 ; 1.1625,343.7039$.
Chart I.

|  | with respect to $\mathrm{PH}_{3}+2 \mathrm{H}$ | with respect to $\mathrm{PH}_{3}+\mathrm{H}_{2}$ |
| :--- | :---: | :---: |
|  | -0.0613 au | +0.0673 au |
| SCF | -0.1041 au | +0.0584 au |
| IEPA | -0.1017 au | +0.0608 au |
| CEPA | -0.0974 au | +0.0651 au |

The binding energies of $\mathrm{PH}_{5}$ with respect to $\mathrm{PH}_{3}+2 \mathrm{H}$ and with respect to $\mathrm{PH}_{3}+\mathrm{H}_{2}$ are in Chart I. The CEPA
values are expected to be closest to reality and are therefore italic. One sees that $\mathrm{PH}_{5}$ is bound by $64 \mathrm{kcal} / \mathrm{mol}$ with respect to $\mathrm{PH}_{3}+2 \mathrm{H}$ but it is unstable with respect to $\mathrm{PH}_{3}$ (planar) $+\mathrm{H}_{2}$ by $38 \mathrm{kcal} / \mathrm{mol}$. One also sees that electron correlation stabilizes $\mathrm{PH}_{5}$ compared to $\mathrm{PH}_{3}+2 \mathrm{H}$ by $0.04 \mathrm{au}(25 \mathrm{kcal} / \mathrm{mol})$ but that the energy difference between $\mathrm{PH}_{5}$ and $\mathrm{PH}_{3}+\mathrm{H}_{2}$ is little affected by correlation.

One may say that the axial $\mathrm{H}-\mathrm{P}-\mathrm{H}$ bond is rather tight, but that $\mathrm{PH}_{5}$ is unstable with respect to $\mathrm{PH}_{3}+\mathrm{H}_{2}$ since the $\mathrm{H}_{2}$ bond is so strong.

A calculation without d AO's yields an SCF energy of -343.4021 for $\mathrm{PH}_{5}\left(D_{3 h}\right)$; the stabilization due to d AO's amounts hence to $0.0552 \mathrm{au}(34 \mathrm{kcal} / \mathrm{mol})$; it is rather close to that obtained for $\mathrm{PH}_{3} \mathrm{~F}_{2}$.

A possible alternative to the $D_{3 h}$ structure is the tetragonal pyramid with $C_{4 v}$ geometry. We assumed the same angles as in tetragonal $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and also took over $r\left(\mathrm{P}-\mathrm{H}_{\text {bas }}\right)$ from $\mathrm{PH}_{3} \mathrm{~F}_{2}$, whereas $r\left(\mathrm{P}-\mathrm{H}_{\mathrm{ap}}\right)$ was chosen as $2.62 a_{0}$ ( $1.39 \AA$ ). The energies in the different approximations and the corresponding differences to the $D_{3 h}$ structure are in Chart II. Taking again the CEPA value as the most reliable Chart II.

|  | $E_{\text {tot }}$, au | $\Delta E$, au |
| :--- | :---: | :---: |
| SCF | -343.4490 | +0.0083 |
| IEPA | -343.6669 | +0.0025 |
| CEPA | -343.6492 | +0.0037 |
| CI | -343.6341 | +0.0047 |

one we find the $C_{4 v}$ structure $0.004 \mathrm{au}(2.5 \mathrm{kcal} / \mathrm{mol})$ above the $D_{3 h}$ structure. With more careful optimization of the geometry this difference will probably get smaller again though we do not expect that it changes its sign.

On the SCF level the energy difference is $5.0 \mathrm{kcal} / \mathrm{mol}$, to be compared with the $3.9 \mathrm{kcal} / \mathrm{mol}$ of ref 3 , whereas the extended Hückel value of $2.1 \mathrm{kcal} / \mathrm{mol}^{2 \mathrm{~b}}$ is surprisingly close to our value that includes correlation effects.

Since the $D_{3 h}$ structure of $\mathrm{PH}_{5}$ does not represent the absolute minimum of the potential hypersurface we wondered whether it is at least a local minimum. To answer this question turned out to be a much harder task than we anticipated. One has namely to calculate the full valence force field including all cross terms and from this then the normal coordinates, and one has then to demonstrate that deformations along any of the normal coordinates lead to an increase of the energy. This investigation is not completed and will be published elsewhere. We have so far shown definitely only that the $D_{3 h}$ structure is stable with respect to deformations to $C_{3 v}$ symmetry, i.e., that $\mathrm{PH}_{5}$ does not prefer an ion cluster $\mathrm{PH}_{4}{ }^{+}-\mathrm{H}^{-}$like $\mathrm{NH}_{3} \mathrm{~F}_{2}$ does.

## 7. $\mathrm{PH}_{4} \mathrm{~F}$ and $\mathrm{PH}_{2} \mathrm{~F}_{3}$

Since $\mathrm{PH}_{3} \mathrm{~F}_{2}$ is a stable molecule and $\mathrm{PH}_{5}$ is not one wonders whether $\mathrm{PH}_{4} \mathrm{~F}$ is stable. The geometry assumed by Strich and Veillard ${ }^{2 a}$ for $\mathrm{PH}_{4} \mathrm{~F}$ is somewhat unrealistic; we therefore used our experience and additional optimization to get better distances. We considered two isomers.

Isomer I was taken as an ideal trigonal bipyramid with an axial F atom and the respective optimized distances from $\mathrm{PH}_{5}$ and $\mathrm{PH}_{3} \mathrm{~F}_{2}$, namely $r\left(\mathrm{PH}_{\mathrm{eq}}\right)=2.58 a_{0}, r\left(\mathrm{PH}_{\mathrm{ax}}\right)=$ $2.806 a_{0}, r(P F)=3.184 a_{0}$.

In isomer II the F atom is equatorial. The PF distance was optimized and obtained as $r(\mathrm{PF})=3.08 a_{0}$; the other distances were taken from $\mathrm{PH}_{5}$, namely $r\left(\mathrm{PH}_{\mathrm{eq}}\right)=2.58 a_{0}$, $r\left(\mathrm{PH}_{\mathrm{ax}}\right)=2.806 a_{0}$.

From the energies collected in Table III one sees that isomer II lies $23 \mathrm{kcal} / \mathrm{mol}$ above isomer I (Strich and Veillard ${ }^{2 a}$ found a difference of $16 \mathrm{kcal} / \mathrm{mol}$ ), but that the more stable isomer I has an energy of $0.0214 \mathrm{au}(13.4 \mathrm{kcal} / \mathrm{mol})$ above that of $\mathrm{PH}_{3}$ (pyramidal) +HF .

We did not investigate the ion pair $\mathrm{PH}_{4}^{+}-\mathrm{F}^{-}$, which may compete with $\mathrm{PH}_{3}+\mathrm{HF}$. For $\mathrm{PH}_{2} \mathrm{~F}_{3}$ we only considered the structure which is suggested from spectroscopic evidence, ${ }^{29}$ namely a trigonal bipyramid with two axial and one equatorial $F$. The angles were taken for idealized geometry (as if the molecule had $D_{3 h}$ symmetry). The bond distances were first taken from $\mathrm{PH}_{4} \mathrm{~F}$ and $\mathrm{PH}_{3} \mathrm{~F}_{2}$ which led to $E=-639.8687 \mathrm{au}$. Then we shortened the PF distances by $2 \%$, taking care of the fact that the $\mathrm{PH}_{2} \mathrm{~F}_{3}$ is somehow between $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PF}_{5}$. This lowered the energy by 0.0044 au ( $2.8 \mathrm{kcal} / \mathrm{mol}$ ). The energy given in Table III was obtained for $r\left(\mathrm{PF}_{\mathrm{ax}}\right)=3.12 a_{0}, r\left(\mathrm{PF}_{\mathrm{eq}}\right)=3.02 a_{0}, r(\mathrm{PH})=$ $2.58 a_{0}$. A comparison of $2 \times \mathrm{PH}_{3} \mathrm{~F}_{2}$ and of $\mathrm{PH}_{2} \mathrm{~F}_{3}+\mathrm{PH}_{4}$ + HF yields $2 \times \mathrm{PH}_{3} \mathrm{~F}_{2}$ lower by $0.015 \mathrm{au}(9.4 \mathrm{kcal} / \mathrm{mol})$. This value can probably be reduced by $\sim 5 \mathrm{kcal} / \mathrm{mol}$ if one optimizes the geometry of $\mathrm{PH}_{2} \mathrm{~F}_{3}$ (which has only $C_{2 v}$ symmetry) more carefully. If one considers further that there should be a hydrogen-bonded interaction between $\mathrm{PH}_{3}+$ HF one expects $2 \times \mathrm{PH}_{3} \mathrm{~F}_{2}$ to be very close in energy to the disproportionation products $\mathrm{PH}_{2} \mathrm{~F}_{3}+\mathrm{PH}_{3}+\mathrm{HF}$. The disproportionation should require practically no activation energy. Only very accurate calculation could decide on whether $\mathrm{PH}_{3} \mathrm{~F}_{2}$ is really unstable with respect to disproportionation, as is suggested from experiment. ${ }^{6}$

## 8. Population Analysis

Some insight into the nature of the chemical bond in the molecules studied here can be gained from a population analysis. If the FXF bond $(X=N, P)$ is a pure three-center four-electron bond the $F$ atoms should have a negative charge of about -0.5 . If, on the other hand, there are two covalent axial XF bonds involving dp hybrids, only a small negative charge on $F$ is expected, but a $d A O$ on $P$ should be occupied by 1.0 electron.

Some care is necessary since atomic populations are not uniquely defined and depend to some extent on the basis used.

We have calculated the Mulliken gross populations ${ }^{30}$ and summed them over all AO's of the same symmetry. We get for each atom separate $s, p$, and $d$ populations (also the components $\mathrm{p}_{x}, \mathrm{p}_{y}, \mathrm{p}_{z}$, etc., are defined), but it is not meaningful (it is only so for a minimum basis set) to distinguish between $1 \mathrm{~s}, 2 \mathrm{~s}$, and 3 s populations, etc. These populations are defined for the total electron distribution but also for any occupied orbital, be it canonical or localized.

The total populations are collected in Table IV. One first notes that the population of the hydrogen s AO's is rather different for the same molecule depending on whether or not p AO's of hydrogen are included. It seems that by allowing for a polarization of the H atom it becomes more attractive and therefore higher populated. The increase of the hydrogen population is between 0.15 and 0.22 electron in all cases. One also realizes that this increased population of hydrogen goes at the expense of N or P and the sum of the populations of the $\mathrm{XH}_{3}$ unit is almost unaffected and so is the total population of the fluorines.

Taking this into account one realizes that the population of the hydrogens is about 0.10 larger in planar $\mathrm{PH}_{3}$ compared to planar $\mathrm{NH}_{3}$ and about 0.30 larger in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ compared to $\mathrm{NH}_{3} \mathrm{~F}_{2}$. The ratio of the s to the ( $\mathrm{p}_{x}+\mathrm{p}_{y}$ ) populations of the valence shell is $1.47: 2.28(1.24: 2.04)$ in $\mathrm{NH}_{3}$ and 1.44:1.82 (1.31:1.62) in $\mathrm{PH}_{3}$ (values in parentheses refer to calculations with p AO's on the hydrogens). For genuine $\mathrm{sp}^{2}$ hybridization this ratio would be $1: 2$. Hence the $\mathrm{p}_{x}$ and $\mathrm{p}_{y} \mathrm{AO}$ 's are much less populated (in $\mathrm{PH}_{3}$ still less than in $\mathrm{NH}_{3}$ ) than what is expected for the appropriate hybrids.

In $\mathrm{NH}_{3} \mathrm{~F}_{2}\left(D_{3 h}\right)$ either F atom has a negative charge of -0.58 which can be compared with the value of -0.5 given
by simple Hückel theory for a four-electron three-center bond assuming the same $\alpha$ for N (or P ) and F . (In the $C_{3 v}$ structure one $F$ has a charge of -0.32 and the other -0.84 .) The negative charge of the F atoms in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ is -0.65 and hence larger than in $\mathrm{NH}_{3} \mathrm{~F}_{2}$ (in agreement with the increased electronegativity difference) if one omits d AO's in the basis. In $\mathrm{NH}_{3} \mathrm{~F}_{2}$ inclusion of d AO's has practically no effect on the charges on the $F$ atoms, and the d AO's are almost unpopulated. In $\mathrm{PH}_{3} \mathrm{~F}_{2}$ the d population is nonnegligible ( 0.21 for $\mathrm{d}_{z^{2}}$ and 0.07 for $\mathrm{d}_{x z}+\mathrm{d}_{y z}$, compared to 0.03 and 0.006 for $\mathrm{NH}_{3} \mathrm{~F}_{2}$ ) but not very large. One sees that the d AO's of $P$ are populated at the expense of the fluorines, which are by about 0.1 less negative if d AO's on P are taken into account. Inclusion of d AO's on F has little effect on the populations, although it lowers the energy considerably.

Comparing $\mathrm{NH}_{3}$ with $\mathrm{NH}_{3} \mathrm{~F}_{2}$ one sees that the bulk of the charge transferred to the fluorines is taken from N ( $\sim 0.8$ units) and the rest $(\sim 0.4)$ from the hydrogens. On nitrogen $\mathrm{p}_{z}$ loses about 1.2 units whereas $\mathrm{s}, \mathrm{p}_{x}$, and $\mathrm{p}_{y}$ gain charge. In $\mathrm{PH}_{3} \mathrm{~F}_{2}$ as compared to $\mathrm{PH}_{3}$ practically the whole charge transferred to the fluorines comes from P and there essentially from $\mathrm{p}_{z}$. If we consider that the FXF bond is mainly formed by $p_{z}$ of $X$ and $p_{z}$ of the two $F$ one realizes that this four-electron three-center bond is highly ionic both in $\mathrm{NH}_{3} \mathrm{~F}_{2}$ and in $\mathrm{PH}_{3} \mathrm{~F}_{2}$; in the latter the increased electronegativity difference is attenuated by the larger participation of d AO's.

The question "sp ${ }^{3} \mathrm{~d}$ hybridization" or "three-center fourelectron bond" can be answered easily. The ratio of the $s, p$, and d valence $A O$ populations should be 1:3:1 for $\mathrm{sp}^{3} \mathrm{~d}^{\text {hy- }}$ bridization; the actual ratios are 1.29:3.05:0.03 in $\mathrm{NH}_{3} \mathrm{~F}_{2}$ and 1.20:2.12:0.21 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$. These ratios together with the documented ionicity establish that three-center four-electron bonds are present, but that they are stabilized by a slight contribution of d AO's.

Back-bonding is obviously not really important for $\mathrm{PH}_{3} \mathrm{~F}_{2}$ (and still less for $\mathrm{NH}_{3} \mathrm{~F}_{2}$ ). The $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ AO's of $P$ that carry back-bonding are together only populated by 0.07 electron, at the expense of the $\mathrm{p}_{x}$ and $\mathrm{p}_{y} \mathrm{AO}$ 's of F .

In $\mathrm{PH}_{5}$ the axial H atoms, which play the role of the F atoms in $\mathrm{PH}_{3} \mathrm{~F}_{2}$, carry a negative charge of 0.34 if no d AO's on P are allowed for and of 0.25 if d AO's are included. From simple MO theory one would expect 0.5 for a genuine three-center four-electron bond. The small electroaffinity of H obviously does not allow such a high negative charge. In fact the sum of the negative charges in the three equatorial H atoms ( 0.39 ) is not very different from that on the two axial H atoms $(0.50)$. The population of $\mathrm{d}_{2^{2}}(0.26)$ is even somewhat higher than that in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ ( 0.21 ), but there is obviously no back-bonding at all in $\mathrm{PH}_{5}$.

A certain equilibration of the effective charges on the ligands, somewhat in contrast to the predictions of simple MO theory, is also observed for $\mathrm{PF}_{5}$. Strich and Veillard ${ }^{2 a}$ found total electron populations of 9.40 and 9.46 for equatorial and axial PF bonds respectively and a total population of 12.88 for P (compared to our values of 13.51 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and 14.10 in $\mathrm{PH}_{5}$ ).

The total population of the d AO's is appreciably higher in $\mathrm{PF}_{5}$ (0.64) than in $\mathrm{PH}_{3} \mathrm{~F}_{2}(0.34)$, but on closer inspection one sees that the population of $\mathrm{d}_{2^{2}}$ does not vary much ( 0.24 in $\mathrm{PF}_{5}$ vs. 0.22 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ ) and the main difference lies in the population of $\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}\left(0.24\right.$ in $\mathrm{PF}_{5}$ vs. 0.04 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ ). The AO's $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ can only contribute to the equatorial PF bonds. Their strong population in $\mathrm{PF}_{5}$ indicates that d AO's are about equally important for the equatorial and for the axial PF bonds. In the $\mathrm{sp}^{3} \mathrm{~d}$ hybridization model $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ are completely ignored.

It seems that in $\mathrm{PF}_{5}$ the difference between the nonequiv-
alent PF bonds is as much attenuated as it can be. The ratio between the $s, p$, and $d_{2} 2$ valence $A O$ population on $P$ is $0.74: 1.50: 0.24$ and hence somewhat closer to the $\mathrm{sp}^{3} \mathrm{~d}$ hybridization ratio than in $\mathrm{PH}_{3} \mathrm{~F}_{2}$. Nevertheless, we think that even in $\mathrm{PF}_{5}$ the $\mathrm{d} A O$ 's on P should be more looked at as polarization functions than in terms of a hybridization model that involves d AO's.

If one tries to simulate $\mathrm{PF}_{5}$ by increasing the nuclear charge on hydrogen in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ such as to account for the electronegativity of fluorine, one is only partially successful. According to ref 3 nuclear charges of 1.117 and 1.243 are equivalent to electronegativities of 3 and 4 respectively in the Pauling scale.

One sees from Table IV that on going from $\mathrm{PH}_{3} \mathrm{~F}_{2}$ via $\mathrm{PH}_{3} \mathrm{~F}_{2}$ (EN3) to $\mathrm{PH}_{3} \mathrm{~F}_{2}$ (EN4) the electron population on H increases by $\sim 0.2$ units, that on $F$ decreases by 0.1 units, and that on $P$ decreases by $\sim 0.5$ units. Only the charges found on F are close to those of $\mathrm{PF}_{5} ;{ }^{2 a}$ the hydrogens (simulating fluorines) have somewhat too little charge (without p's on H these charges would be even smaller) and P has somewhat too high electron population. The $d$ population on $P$ is well accounted for as far as $\mathrm{d}_{z^{2}}$ is concerned ( 0.22 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ (EN4) compared to 0.24 in $\mathrm{PF}_{5}$ ) but the population of $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ is a factor 2 too small ( 0.08 compared to 0.16 ), i.e., back-bonding in the three-center FPF bond is underestimated. The $\mathrm{d}_{x y}$ and $\mathrm{d}_{x^{2}-y^{2}}$ orbitals were not considered in this comparison because they have only a population of 0.036 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and are unlikely to be higher populated in the simulated $\mathrm{PF}_{5}$, whereas in "real" $\mathrm{PF}_{5}$ they have a population of 0.24 mainly due to polarization of the equatorial PF bonds and equatorial PF-quasi-back-bonding, which can of course not be simulated by H with an extra positive charge.

## 9. Discussion of the MO Energies

In Table V the orbital energies of the interesting molecules are compiled in such a way that MO's that correspond to each other are on the same line. The energies of the MO's involved in the three-center four-electron bond are italicized. In looking for an essential difference between $\mathrm{NH}_{3}$ and $\mathrm{PH}_{3}$ (both planar) one realizes that the orbital energies of the $p_{z}$ lone pairs, that are via Koopmans' theorem related to the respective ionization potentials, differ appreciably, being $0.2865 \mathrm{au}(7.8 \mathrm{eV})$ for $\mathrm{PH}_{3}$ and 0.3787 au $(10.3 \mathrm{eV})$ for $\mathrm{NH}_{3}$. This difference is in contrast to the rather close experimental vertical ionization potentials ${ }^{31}$ $\left(\mathrm{NH}_{3}: 10.85 \mathrm{eV} ; \mathrm{PH}_{3}: 9.9 \mathrm{eV}\right)$ but one has to note that the latter correspond to the pyramidal equilibrium geometries and that the lone pair in $\mathrm{NH}_{3}$ is more like an $\mathrm{sp}^{3}$ hybrid and that in $\mathrm{PH}_{3}$ more like a pure s AO , though both are hybrids.

Comparing $\mathrm{NH}_{3} \mathrm{~F}_{2}$ to $\mathrm{PH}_{3} \mathrm{~F}_{2}$ one finds that the levels of the $\pi$ AO's of F in $\mathrm{NH}_{3} \mathrm{~F}_{2}\left(3 \mathrm{E}^{\prime}\right.$ and $1 \mathrm{E}^{\prime \prime}$ ) are only split by $\sim 0.02$ au but they are split by $\sim 0.07 \mathrm{au}$ in $\mathrm{PH}_{3} \mathrm{~F}_{2}(\sim 0.05$ without d AO's). In both cases $1 \mathrm{E}^{\prime \prime}$ is lower. Since there is no other $E^{\prime \prime}$ MO and since the increase of the splitting due to d (i.e. due to back-bonding) is only 0.02 (in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ ) the splitting is probably due to an "interaction" of $3 \mathrm{E}^{\prime}$ with other E' MO's and not to a direct interaction of the $\pi$ AO's of the fluorines. The MO energy of a fluorine $\pi \mathrm{AO}$ in HF (in the same basis) is 0.6517 au ; the corresponding MO energies in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{NH}_{3} \mathrm{~F}_{2}$ are in agreement with the somewhat higher negative charge on F in the latter compound.

Now, according to simple MO theory, the nonbonding $6 \mathrm{~A}_{1}{ }^{\prime} \mathrm{MO}$ that is part of the three-center four-electron bond should be built up from $p_{z}$ AO's of the fluorines and have the same energy as the fluorine p AO. In $\mathrm{NH}_{3} \mathrm{~F}_{2}$ the energy of this "nonbonding" MO is as much as $\approx 0.1$ au higher than that of the $\mathrm{E}^{\prime \prime} \pi \mathrm{MO}$ (which is regarded as a "true"

Table V. Orbital Energies (Negative, in au) (the Orbitals Involved in the Three-Center Four-Electron Bond are Italic)

$a$ Or HXH.
nonbonding MO ); in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ the respective difference is $\approx$ 0.05 . In either molecule the formally nonbonding MO of the three-center bond is appreciably destabilized (and hence in a sense antibonding), more in $\mathrm{NH}_{3} \mathrm{~F}_{2}$ than in $\mathrm{PH}_{3} \mathrm{~F}_{2}$. (Of course part of this "destabilization" can come from "interaction" with other $\mathrm{A}_{1}{ }^{\prime}$ MO's like the similar "destabilization" of $\mathrm{E}^{\prime}$ with respect to $\mathrm{E}^{\prime \prime}$, but unpublished model calculations where such an interaction is excluded demonstrated similar destabilization of the formally nonbonding MO.)

The binding $4 \mathrm{~A}_{2}{ }^{\prime \prime} \mathrm{MO}$ of the three-center bond has about the same energy in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{NH}_{3} \mathrm{~F}_{2}$. We further note that although in $\mathrm{NH}_{3}$ the highest occupied MO is about 0.1 au lower in energy than in $\mathrm{PH}_{3}$, in $\mathrm{NH}_{3} \mathrm{~F}_{2}$ vs. $\mathrm{PH}_{3} \mathrm{~F}_{2}$ the P compound has the lower highest occupied MO (by $\sim 0.08 \mathrm{au}$ ).

## 10. Orbital Contraction, 3d vs. 4s Participation

If one plots the expansion coefficients of the gaussians in one orbital as a function of the orbital exponent one gets a maximum for what one may call the "optimum exponent", which is rather insensitive to the size of the expansion. In the free $P$ atom the optimum exponents for $1 \mathrm{~s}, 2 \mathrm{~s}, 2 \mathrm{p}, 3 \mathrm{~s}$, and 3 p are roughly $45,2,3,0.2$, and 0.2 respectively. We conclude that a spectroscopic 3 d AO should have $\eta \approx 0.2$ (or rather less since it is expected to be more shielded than 3 s and 3 p ), whereas a polarization-type 3 d should have roughly the same $\eta$ as the 3 s and 3 p that it polarizes. In the MO's of the PH bonds in $\mathrm{PH}_{3}$ the optimum exponents are not much changed; in $\mathrm{PH}_{3} \mathrm{~F}_{2}$, however, one finds for 3 s and 3 p in the $5 \mathrm{~A}^{\prime}$ and $2 \mathrm{E}^{\prime}$ MO's 0.5 and 0.4 , i.e., the optimum exponents of 3 s and 3 p are multiplied by roughly a factor of 2. This is a semiquantitative illustration of what is usually referred to as "orbital contraction" as a consequence of the effective positive charge on $P$. The optimum exponent for a d AO in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ is close to 0.5 , hence similar to that of the "contracted" 3 s and 3 p AO's, but far from that of a spectroscopic 3d AO. At variance with the large optimum exponent of 0.5 for s in the $5 \mathrm{~A}_{1}{ }^{\prime} \mathrm{MO}$ (see Table IV) that has to do with the PH bonds, the optimum exponent of s in the (formally nonbonding) $6 \mathrm{~A}_{1}{ }^{\prime} \mathrm{MO}$ is only 0.13 . In $6 \mathrm{~A}_{1}{ }^{\prime}$ this "diffuse" s AO enters with a coefficient 0.18 that is close to that of the $d_{z^{2}}$ AO (0.16). One is tempted to state that we are in fact dealing with a 4 s AO of P which is involved in $6 \mathrm{~A}_{1}{ }^{\prime}$ to about the same extent as $3 \mathrm{~d}_{z^{2}}$, although it is not too meaningful to assign quantum numbers to AO's in a molecule unless one has used a minimal basis. We also note that in order to compare the size (the "bohr radius") of an AO one should not just compare the orbital exponents but also consider that a d AO contains a factor $r^{2}$, a $p$ AO only a
factor $r$. We ignore this since our argument is only semiquantitative anyway.

## 11. Role of the Ionization Potential of $\mathbf{X H}_{3}(\mathbf{X}=\mathbf{P}, \mathbf{N})$ and Electron Affinity of F (with respect to H ) for the Stability of the Three-Center Bond

The simplest realistic model of a four-electron BAB bond (with two electrons from $A$ and one from either $B$ ) consists probably in building this bond in two steps: (a) formation of $\mathrm{AB}^{+}+\mathrm{B}^{-}$; (b) "resonance" stabilization to BAB.
The energy involved in step (a) consists of: (1) the ionization potential of $A$; (2) the electron affinity of $B$; (3) the net Coulomb interaction at the equilibrium distance between $\mathrm{AB}^{+}$and $\mathrm{B}^{-}$; (4) the covalent binding energy between $\mathrm{A}^{+}$ and $B$.

According to simple MO theory step (b) should amount to an energy gain of $(\sqrt{2}-1)$ times the binding energy of A and $\mathbf{B}^{+}$if this bond is ideally covalent, and to zero if this bond is purely ionic. So we expect something of the order of $20 \%$ of this binding energy, i.e., at best $20 \mathrm{kcal} / \mathrm{mol}$, a quantity that is almost negligible with respect to the other energies that we discuss.

If the ABA bond is not completely a three-center fourelectron bond, but is appreciably stabilized through d AO's, we have to add another step: (c) stabilization through participation of d AO's.

Using this simple model, identifying the ionization potential of $\mathrm{XH}_{3}$ with the respective MO energy, taking the experimental electron affinity of $\mathrm{F}(3.5 \mathrm{eV}=0.13 \mathrm{au})$ assuming a Coulomb attraction of $0.24 \mathrm{au}^{32}$ (corresponding to a distance of $4.3 a_{0}$ between ideal point charges), taking 0.08 au for the $\mathrm{AB}^{+}$binding energy, and taking the improvements due to d AO's from our calculations, we get the binding energies (au) (with respect to $\mathrm{XH}_{3}+2 \mathrm{~F}(2 \mathrm{H})$ ) in Chart III. These values are in very rough agreement with those

Chart III.

|  | $\mathrm{NH}_{3} \mathrm{~F}_{2}$ | $\mathrm{PH}_{3} \mathrm{~F}_{2}$ | $\mathrm{PH}_{5}$ |
| ---: | ---: | ---: | ---: |
|  | 0.38 | 0.29 | 0.29 |
| a 1 | -0.13 | -0.13 | -0.03 |
| 2 | -0.24 | -0.24 | -0.24 |
| 3 | -0.08 | -0.08 | -0.08 |
| 4 | $\underline{-0.00}$ | $\underline{-0.06}$ | $\underline{-0.06}$ |
| c | -0.07 | -0.22 | -0.13 |

actually calculated. We can say that the difference in binding energy of $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{NH}_{3} \mathrm{~F}_{2}$ is to roughly $50 \%$ due to the difference in ionization potentials of $\mathrm{NH}_{3}$ and $\mathrm{PH}_{3}$ (planar) and to $50 \%$ due to d AO's.

## 12. Reliability of the Results

The basis sets were chosen so that with relatively little computational effort they account for energy differences rather close to those obtained at the Hartree-Fock-limit; i.e., the deficiencies of our basis sets are mainly intraatomic. The errors that are still present in the computed energy differences are hence due to correlation. We see from the results for $\mathrm{PH}_{5}$ that, in fact, the binding energy with respect to $\mathrm{PH}_{3}+2 \mathrm{H}$ is strongly underestimated in the HartreeFock approximation (by $\approx 0.04 \mathrm{au}=25 \mathrm{kcal} / \mathrm{mol}$ ), whereas the error in the binding energy with respect to $\mathrm{PH}_{3}+\mathrm{H}_{2}$ is in error by only $\approx 3 \mathrm{kcal} / \mathrm{mol}$. We expect something similar for $\mathrm{NH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{3} \mathrm{~F}_{2}$, i.e., that the binding energies with respect to $\mathrm{XH}_{3}+2 \mathrm{~F}$ are substantially higher (in absolute value) than those calculated in Hartree-Fock approximation ( $\sim 0$ and $170 \mathrm{kcal} / \mathrm{mol}$, respectively), whereas those with respect to $\mathrm{XH}_{3}+\mathrm{F}_{2}$ (or $\mathrm{XH}_{2} \mathrm{~F}+\mathrm{HF}$ ) should be close to the actual ones (see also the end of section 4).

For those molecules which have been treated previously by ab initio calculations, namely $\mathrm{PH}_{5}$ and $\mathrm{PH}_{4} \mathrm{~F}$, we claim that our results are more reliable since we have used better balanced basis sets and spent more care on geometry optimizations. The populations tabulated in this paper should not be taken too literally mainly in view of their basis dependence, but the discussed differences between different molecules are surely significant. The same is true for the orbital energies.

## 13. Conclusions

(1) $\mathrm{PH}_{3} \mathrm{~F}_{2}$ is a more typical example of a molecule with one electron-rich three-center bond and three ordinary bonds than is $\mathrm{PF}_{5}$ or $\mathrm{PH}_{5}$ where the difference of the two kinds of bonds is much attenuated.
(2) Molecules like $\mathrm{PH}_{3} \mathrm{~F}_{2}$ or $\mathrm{PF}_{5}$ would be stable without any participation of $d$ AO's on $P$. The d AO's stabilize the FPF bond (by $\approx 40 \mathrm{kcal} / \mathrm{mol}$ ) but they are not essential. ${ }^{33}$ The stabilization through d AO's is about the same in $\mathrm{PH}_{5}$ as in $\mathrm{PH}_{3} \mathrm{~F}_{2}$, but it is one order of magnitude smaller in $\mathrm{NH}_{3} \mathrm{~F}_{2}$. The population of the $\mathrm{d}_{z^{2}} \mathrm{AO}$ of P is $\approx 0.02$ in $\mathrm{NH}_{3} \mathrm{~F}_{2}$ and $\approx 0.22$ in $\mathrm{PH}_{3} \mathrm{~F}_{2}$, i.e., in either molecule it is much less than what is required for $\mathrm{sp}^{3} \mathrm{~d}$ hybridization. The surprisingly high d populations found in CNDO calculations ${ }^{4}$ are an artifact of the CNDO scheme and deserve no further comment.
(3) A decisive factor for the stability of $\mathrm{XH}_{3} \mathrm{~F}_{2}$ with respect to $\mathrm{XH}_{3}+2 \mathrm{~F}$ is the ionization potential of the $\mathrm{p}_{2} \mathrm{AO}$ of planar $\mathrm{XH}_{3}$. The lower ionization potential of planar $\mathrm{PH}_{3}$ (orbital energy 7.8 eV ) compared to $\mathrm{NH}_{3}(10.3 \mathrm{eV})$ is to a large part responsible for the fact that $\mathrm{PH}_{3} \mathrm{~F}_{2}$ is a stable molecule whereas $\mathrm{NH}_{3} \mathrm{~F}_{2}$ is not. Similarly important is the large electron affinity of F . That $\mathrm{PH}_{5}$ is not stable is in part due to the small electron affinity of H .
(4) In $\mathrm{PF}_{5}$ the equatorial PF bonds render the P atom very positive $\left(+2.1\right.$ compared to +1.4 in $\left.\mathrm{PH}_{3} \mathrm{~F}_{2}\right)$ and stabilize indirectly the axial three-center bond. This extra stabilization results mainly from a stronger electrostatic attraction: the $\mathrm{d}_{z^{2}}$ participation is not increased compared to $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and back-bonding only slightly so. The axial PF bond length in $\mathrm{PF}_{5}$ is $1.57 \AA$ compared to $1.68 \AA$ in $\mathrm{PH}_{3} \mathrm{~F}_{2}$.
(5) The presence of back-bonding is demonstrated by the population of $\mathrm{d}_{x z}+\mathrm{d}_{y z}$ of 0.08 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and 0.16 in $\mathrm{PF}_{5}$ accompanied by a similar decrease of ( $\mathrm{p}_{x}+\mathrm{p}_{y}$ ) population on F . In $\mathrm{PH}_{3} \mathrm{~F}_{2}$ the energy improvement due to back-bonding is $\approx 15 \mathrm{kcal} / \mathrm{mol}$ (roughly half the energy improvement due to participation of $\mathrm{d}_{2^{2}}$ ). In $\mathrm{PF}_{5}$ an analysis of backbonding is obscured by the fact that $\mathrm{d}_{x z}$ and $\mathrm{d}_{y z}$ can also participate in back-bonding with the equatorial $F$ atoms. In $\mathrm{PF}_{5}$ there is also a strong polarization of the equatorial PF
bonds and some inplane "quasi-back-bonding" (there is no in-plane $\sigma-\pi$ separation) documented by a population of 0.24 of $\mathrm{d}_{x y}+\mathrm{d}_{x^{2}-y^{2}}$ (compared to only 0.04 in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ ). There is no back-bonding possible in $\mathrm{PH}_{5}$.
(6) Both $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{5}$ in $D_{3 h}$ geometry are stable with respect to deformation to $C_{3 v}$, whereas $\mathrm{NH}_{3} \mathrm{~F}_{2}$ is not. $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PH}_{5}$ want to have a symmetric axial bond, whereas $\mathrm{NH}_{3} \mathrm{~F}_{2}$ prefers to consist of an ion pair $\mathrm{NH}_{3} \mathrm{~F}^{+}$ $\mathrm{F}^{-}$. The reason for this difference is not yet understood since according to simple MO theory the symmetric structure should be more stable by about 10 to $20 \mathrm{kcal} / \mathrm{mol}$. Possibly the larger d participation in the P compounds is responsible for the preference to the symmetric structure, though the existence of the symmetric $\mathrm{FHF}^{-}$proves that symmetric structures are possible without d participation. In $\mathrm{NH}_{3} \mathrm{~F}_{2}$ the $D_{3 h}$ structure is only $12 \mathrm{kcal} / \mathrm{mol}$ above the $C_{3 v}$ structure.
(7) One can say that in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ the 3 s and 3 p AO's are contracted significantly compared to those in the $P$ atom and that there is the participation of a 4 s-like $A O$ in the $6 \mathrm{~A}_{1}{ }^{\prime}$ MO. The d AO in $\mathrm{PH}_{3} \mathrm{~F}_{2}$ and $\mathrm{PF}_{5}$ is rather different from a spectroscopic d AO. It is roughly as contracted as 3 s and 3 p.
(8) $\mathrm{XH}_{3} \mathrm{~F}_{2}$ need not be a stable molecule, even if it is bound with respect to $\mathrm{XH}_{3}+2 \mathrm{~F}$ and even with respect to $\mathrm{XH}_{3}+\mathrm{F}_{2}$. Another decomposition is that into $\mathrm{XH}_{2} \mathrm{~F}+$ HF. In fact $\mathrm{NH}_{3} \mathrm{~F}_{2}$ is stable with respect to $\mathrm{NH}_{3}+\mathrm{F}_{2}$ but not with respect to $\mathrm{NH}_{2} \mathrm{~F}+\mathrm{HF}$, whereas $\mathrm{PH}_{3} \mathrm{~F}_{2}\left(D_{3 h}\right)$ is lower in energy than all other arrangements of the same atoms.

Acknowledgment. The authors thank Dr. R. Ahlrichs for valuable discussions and computer programs; without his new integral program ${ }^{34}$ this study could not have been performed. The computations were carried out at the UNIVAC 1108 of the computer center of the University of Karlsruhe. We are grateful to the staff of this center. We also thank Dr. V. Staemmler and Dr. H. Kollmar for comments on the manuscript.

# Group Theoretical Selection Rules for the Transition States of Chemical Reactions 

Richard E. Stanton ${ }^{19}$ and James W. McIver, Jr.*1b<br>Contribution from the Departments of Chemistry, Canisius College, Buffalo, New York 14208, and State University of New York at Buffalo. Buffalo, New York 14214. Received September 20, 1974

#### Abstract

The transition state of a chemical reaction is the lowest barrier separating reactants and products on a potential energy surface. As such it is a critical point on the surface and its force constant matrix has exactly one negative eigenvalue. The corresponding eigenvector is defined to be the transition vector for the reaction. Schur's lemma implies that the transition vector will belong to one of the symmetry species of the transition state point group provided sufficient care is taken in the choice of the coordinate system. Consideration of the effect of transition state symmetry operations on the reactants and products and on the paths joining them to the transition state leads to a series of theorems governing the transformation properties of the transition vector. In some cases these requirements are incompatible with the known transformation properties of the available symmetry species for the proposed transition state. It is shown that such "transition states" are forbidden; i.e., they cannot be the lowest barriers separating reactants from products. The concept of symmetry forbidden transition states is applied to a series of reactions of gradually increasing complexity. Included (among others) are the classic $\mathrm{H}+$ $\mathrm{H}_{2}$ exchange reaction, the $\mathrm{T}+\mathrm{CH}_{4}$ displacement reaction, the olefin metathesis reaction, the inversion of cyclohexane, and the Cope reaction.

## I. Introduction

The concept of the transition state plays a central role both in the formal theory of reaction rates and in the way in which the chemist actually visualizes a reaction. The experimental determination of transition state geometries, however, is a very difficult problem. It is in fact probably fair to say that no currently available experiment or combination of experiments can yield anything better than a fuzzy view of the transition state of any particular reaction. It is natural, therefore, that there has in recent years been a series of attempts to calculate transition state energies and geometries by the various quantum mechanical techniques that were developed for equilibrium states. We shall refer to many of these computations in the body of this paper. The methods employed range from simple Hückel theory to the most expensive ab initio calculations. There have also been papers dealing with the special properties of transition states and with the problems involved in finding these states on a potential surface.

Murrell and Laidler ${ }^{2 a}$ have emphasized the requirement that the transition state force constant matrix have exactly one negative eigenvalue and have given a formal proof of this condition. Murrell and Laidler also tried to use their theorem to derive selection rules for transition state geometries. In doing so they made no use of group theory and were led into some unwarranted assumptions that destroyed the validity of some of their conclusions. These errors were later pointed out by Murrell and Pratt. ${ }^{2 b}$

In this paper we will, like Murrell and Laidler, be looking for selection rules and will make extensive use of the Murrell and Laidler (hereafter M-L) theorem. We avoid the traps associated with faulty geometric intuition by combin-
ing the M-L theorem with formal group theory. ${ }^{3}$ It might be mentioned that the $\mathrm{M}-\mathrm{L}$ theorem also has important consequences which go beyond the scope of the present paper. It has been shown elsewhere, ${ }^{4}$ for example, that M-L often requires that off-diagonal bond interaction force constants play a dominant role in the transition state, in marked contrast to their ordinarily minor role in equilibrium states.

Salem et al. ${ }^{5}$ have defined as "narcissistic reactions" those in which reactants and products are related to one another via some improper rotation. They also discuss conditions which make a symmetric transition state probable or improbable for these reactions and stress the computational advantages associated with knowing the symmetry properties of the transition state prior to carrying out a computer search. These ideas can be generalized. We show that proper as well as improper rotations can convert reactants into products. Moreover, as indicated above, one can in many cases make rigorous statements concerning the allowed symmetry of the transition state for such reactions.

To a certain extent the computational advantage of knowing the symmetry of a transition state is the same as in knowing the symmetry of an equilibrium state; it enables one to reduce the number of coordinates that must be varied in the search for the transition state. Since the number of points required to map out a potential surface varies exponentially with the number of internal coordinates and since most reactions of interest involve a large number of coordinates the computational gain in reducing the number of coordinates can be very great. One practical way of achieving this gain is through the introduction of symmetry adapted coordinates. The search for the transition state can then be restricted to the subspace of fully symmetric coordinates.
