It is likely that the spectra observed for COHb were in fact due to $\mathrm{O}_{2} \mathrm{Hb}$ generated by traces of $\mathrm{O}_{2}$ during laser-induced photodissociation of COHb . This problem can be minimized by using low laser power and increasing the concentration of $\mathrm{Hb} .{ }^{17 \mathrm{a}}$

(36) (a) It is natural to inquire about the source of this difference if it is not intermolecular. Greater doming should be energetically disfavored to the
extent that it reduces $\pi$ conjugation in the porphyrin ring. On the other hand It does provide better orientation of the pyrrole nitrogen lone pairs for bonding to the dlsplaced iron atom. A model of the ( $2-\mathrm{Melm}$ ) Fell(TPP) structure shows the pyrrole rings to be nearly colinear with the iron-nitrogen bonds. Orbltal following may be less important for high-spin Fe(III) which has a half-fllled (spherical) d subshell. It may be significant in this regard that the average $\mathrm{Fe}-\mathrm{N}$ (pyrrole) distance, ${ }^{27} 2.086 \mathrm{~A}$, is nearly the same in (2-Melm)Fe ${ }^{I \prime}(T P P)$ as in high-spin Fe (III) porphyrins, $2.07 \AA$ (average), although the high-spin octahedral ionic radius is $\sim 0.12 \AA$ less for Fe (III) than for $\mathrm{Fe}(\mathrm{II}){ }^{37}$ While the ionic radius is not an appropriate comparison for the porphyrin complexes, the similar Fe -N(pyrrole) distances for Fe (II) and Fe(III) do suggest a stronger than usual bond for the former. Thls line of reasoning must remain speculative, however, pending the availability of further structural data, especially for other high-spin $\mathrm{Fe}(I I)$ hemes. (b)
 the same as the solution spectra (see Figure 1), suggesting no significant structural differences between crystal and solution.

(38) Spaulding et al. ${ }^{13 \mathrm{a}}$ prefer to attribute the extra shift In band IV of methemoglobin to an expansion of the porphinato core, similar to that which occurs in $\mathrm{Cl}_{2} \mathrm{Sn}^{1 \mathrm{~V}} \mathrm{Et}_{8} \mathrm{por},{ }^{39}$ which also gives a low value for band IV. ${ }^{133}$ For a fixed Fe -pyrrole distance, this would allow the iron atom to fall further into the central hole. This Interpretation puts Spaulding et al, in the position of inferring that the iron atom is closer to being in the heme plane in methemoglobin than in high-spin model compounds, even though the frequency shifts from the low-spin planar values are greater for the protein. It is unclear how an expansion of the porphinato core could be accomplished physically. Spaulding et al. suggest that the iron atom is pulled toward the plane by the sixth ligand, in the distal position. The effect of this should simply be to depopulate the iron $d_{x^{2}-y^{2}}$ orbltal (intermediate or low-spin state, vide infra) allowing the Fe-pyrrole bond to shorten.

#### Abstract

The solid state structure of beryllium bis(octahydrotriborate), $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$, consists of two bidentate $\mathrm{B}_{3} \mathrm{H}_{8}{ }^{-}$ligands bound to a central beryllium atom by two $\mathrm{Be}-\mathrm{H}-\mathrm{B}$ bridge hydrogen bonds from adjacent boron atoms in each $\mathrm{B}_{3} \mathrm{H}_{8}-$ unit. Crystals of $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ form in the monoclinic space group $P 2_{1} / n$ with unit cell parameters $a=10.503$ (8) $\AA, b=7.641$ (3) $\AA, c=11.399$ (9) $\AA, \beta=118.49(6)^{\circ}, V=804$ (1) $\AA^{3}$, and $Z=4$. The x-ray crystal structure was solved by direct methods and refined to $R_{1}=0.050$ and $R_{2}=0.061$ for 944 independent observed reflections. The molecule has molecular $C_{2}$ symmetry with an approximately tetrahedral beryllium atom and $\mathrm{B}_{3} \mathrm{H}_{8}-$ ligands essentially undistorted from free $\mathrm{B}_{3} \mathrm{H}_{8}-$ in their internal bonding. $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ is the first reported metal complex having two octahydrotriborate ligands bound to a metal.

Beryllium bis(octahydrotriborate), $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$, is a colorless liquid prepared by gently heating an intimate mixture of $\mathrm{TlB}_{3} \mathrm{H}_{8}$ and $\mathrm{BeCl}_{2}$ in vacuo. ${ }^{2}$ Preliminary variable-temperature ${ }^{11} \mathrm{~B}$ and ${ }^{1} \mathrm{H}$ NMR studies indicated three basic molecular forms. The two higher temperature forms correspond to partially and completely fluxional molecules, while the low temperature form (observed below $-10^{\circ}$ ) appeared to be static and have $C_{2}$ molecular symmetry. In order to confirm the NMR analysis we initiated a low-temperature single-crystal x-ray determination of the static configuration of $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$.

## Structure Determination

Single-Crystal X-Ray Data, The $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ used was prepared and purified as previously described. ${ }^{2}$ Due to the compound's extreme air sensitivity, it was necessary to load and seal the Pyrex x-ray capillaries on the vacuum line. ${ }^{3}$ A capillary containing liquid $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ (mp $-51^{\circ}$ ) was placed on a Syntex P1̄ four-circle computer-controlled diffractometer equipped with low-temperature accessories, and an irregularly shaped single-crystal was grown at $-77 \pm 3^{\circ}$. The low crystal-growing temperature was necessary because of the tendency of $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ to supercool. The crystal was subsequently cooled to $-175 \pm 5^{\circ}$ and 15 diffraction maxima were automatically centered

Figure 1. The static molecular structure of $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ showing the numbering system used in this paper. In this ORTEP diagram, $50 \%$ probability contours were plotted for the atomic vibration ellipsoids. The hydrogen atoms are represented by spheres of $0.14 \AA$ radius.

Figure 2. A stereoscopic view of $\operatorname{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$.
in $2 \theta, \chi$, and $\omega$. Graphite monochromated Mo $\mathrm{K} \alpha(\lambda 0.7107 \AA$ ) radiation was used throughout the alignment and data collection procedures. The Syntex routines ${ }^{4}$ indicated a monoclinic lattice with dimensions of $a=10.503$ (8) $\AA, b=7.641$ (3) $\AA, c=11.399$ (9) $\AA$, $\beta=118.49(6)^{\circ}$, and unit cell volume $=804$ (1) $\AA^{3}$. Systematic absences for $0 k 0$ with $k=$ odd and $h 0 l$ with $h+l=$ odd indicated that the space group was $P 2_{1} / n$ (nonstandard setting of $P 2_{1} / c\left(C_{2 h}{ }^{5}\right.$, No. 14)). The equivalent positions for this space group are $x_{1} y_{i} z_{i}, \bar{x}, \bar{y}, \bar{z}$ i $1 / 2+x, 1 / 2-y, 1 / 2+z$; and $1 / 2-x, 1 / 2+y, 1 / 2-z$. The monoclinic symmetry and associated lattice constants were verified by partial rotation photographic projections along each of the three reciprocal axes. Because of the low melting point of $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$, a density could not be conveniently determined. The calculated density of $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ is $0.743 \mathrm{~g} / \mathrm{cm}^{3}$ (at $-175^{\circ}$ ) with $Z=4$. This is a typical density for a compound of this type; e.g., the reported density of $\mathrm{Be}\left(\mathrm{BH}_{4}\right)_{2}$ is 0.609 $\mathrm{g} / \mathrm{cm}^{3}$. ${ }^{5}$

Intensity data were collected using the $\theta-2 \theta$ scan technique with variable scan speeds (from 2 to $24^{\circ} / \mathrm{min}$ ) with each background count lasting two-thirds of the time used for the scan count. Two standard reflections ( 020 and 002 ) were monitored every 50 reflections during the entire data collection procedure and showed no significant deviation in intensity. All data were collected with the crystal temperature held at $-175 \pm 5^{\circ}$. A total of 1638 reflections were collected over the range $3.0^{\circ} \leq 2 \theta<50.0^{\circ}$. The data were reduced in the usual manner, with the standard deviation of each corrected intensity estimated from the formula $\sigma(I)=T_{\mathrm{R}}\left[S+\left(B_{1}+B_{2}\right) / B_{\mathrm{R}}{ }^{2}+q(I)^{2}\right]^{1 / 2}$, where $T_{\mathrm{R}}$ is the $2 \theta$ scan rate in degrees per minute, $S$ is the total integrated scan count, $B_{1}$ and $B_{2}$ are the background counts, $B_{\mathrm{R}}$ is the ratio of the background to scan count times, and $q$ is set equal to 0.003 . The merged data yielded 1138 independent reflections, of which 944 were observed ( $I>2.0 \sigma(I)$ ) and were used in the solution and refinement of the structure.

${ }^{a}$ All atoms closer than $\pm 0.2 \AA$ to the defined plane are listed. ${ }^{b}$ In $\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} \mathrm{CuB}_{3} \mathrm{H}_{8}$ these bridge hydrogens are +0.2 and $-0.8 \AA$ out of the plane defined by the boron atoms. S. J. Lippard and K. M. Melmed, Inorg. Chem., 8, 2755 (1969). ${ }^{c}$ In $\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} \mathrm{CuB}_{3} \mathrm{H}_{8}$ these bridge hydrogens are 0.38 and $0.40 \AA$ above the $\mathrm{CuB}(1) \mathrm{B}(3)$ plane.
0.050 and $R_{2}=0.061$ when the nonhydrogen atoms were allowed anisotropic thermal motion. The final data to parameter ratio was 7.4. The standard deviation in an observation of unit weight was $1.46 .{ }^{8 \mathrm{c}}$ Refinement of the hydrogen atoms anisotropically is not warranted by the data to parameter ratio. ${ }^{9}$ The scattering factors of Hanson et al. ${ }^{10}$ were used for the nonhydrogen atoms and those of Stewart et al. ${ }^{11}$ for the hydrogen atoms. All least-squares refinements were based on the minimization of $\Sigma w_{\mathrm{i}}\left(\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$, with the weights $w_{\mathrm{j}}$ set equal

Figure 3. A view of the $\operatorname{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ molecule looking down the $C_{2}$ axis.
to $1 / \sigma_{\left(F_{0}\right)^{2}}$. The estimated standard deviations given in the tables in this paper were calculated from the full variance-covariance matrix obtained from the last least-squares refinement cycle.

## Description of the Structure

The static molecular structure of the $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ molecule and the numbering system used in this study are shown in Figure 1. The stereoscopic projection is shown in Figure 2. The atomic coordinates and isotropic thermal parameters of the hydrogen atoms in $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ are listed in Table I, and the anisotropic temperature factors for the nonhydrogen atoms are listed in Table II. Interatomic distances and intramolecular angles are listed in Tables III and IV, respectively, and Table $V$ lists the deviations of several atoms from their idealized plane positions. Observed and calculated structure factors are also given; see paragraph at end of paper regarding supplementary material. Although the space group $P 2_{1} / n$ does not require any molecular symmetry (none was used in the structural refinement), the $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ molecule possesses $C_{2}$ symmetry, verified by the close agreement observed for the symmetry-related bond lengths and angles (see Tables III and IV). A view of $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ looking down the $C_{2}$ axis is shown in Figure 3. Beryllium bis(octahydrotriborate) exists as discrete molecules with normal van der Waals packing. All contacts between molecules were examined. The shortest nonhydrogen contact is $3.838 \AA$ between $\mathrm{B}\left(1^{\prime}\right)$ and $\mathrm{B}\left(2^{\prime}\right)(1 / 2+x, 1 / 2-y, 1 / 2+z)$. The closest intermolecular nonbonding distance between a hydrogen and a nonhydrogen atom is $3.217 \AA$ between $\mathrm{B}\left(2^{\prime}\right)$ and $H\left(1^{\prime}\right)(-1 / 2+x,-1 / 2-y,-1 / 2+z)$. The shortest contact between hydrogen atoms is the $2.608 \AA$ separation between $\mathrm{H}\left(3^{\prime}\right)$ and $\mathrm{H}\left(7^{\prime}\right)(-1 / 2-x,-1 / 2+y, 1 / 2-z)$.

The $\mathrm{B}_{3} \mathrm{H}_{8}$ group functions as a bidentate ligand in $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ and except for (CO) ${ }_{3} \mathrm{MnB}_{3} \mathrm{H}_{8},{ }^{12}$ this is the only mode of attachment known for this ligand. Beryllium bis(octahydrotriborate) is the first example of a metal complex having two $\mathrm{B}_{3} \mathrm{H}_{8}-$ ligands. ${ }^{13}$

The bonding in $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ is electron deficient in nature, as illustrated by the four $\mathrm{Be}-\mathrm{H}-\mathrm{B}$ three-center two-electron bonds to beryllium. Each of these $\mathrm{Be}-\mathrm{H}-\mathrm{B}$ localized bonds can be considered to be comprised of one $\mathrm{sp}^{3}$ orbital from the beryllium atom, one $\mathrm{sp}^{3}$ orbital from the boron atom, and the hydrogen $s$ orbital. The average $\mathrm{Be}-\mathrm{H}-\mathrm{B}$ angle of $94.2^{\circ}$ in $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ is probably a result of electronic rather than stereochemical effects, since the s orbital of the hydrogen atom has a spherical distribution and can thus bond equally well regardless of the $\mathrm{Be}-\mathrm{H}-\mathrm{B}$ angle. The average $\mathrm{Be}-\mathrm{H} \mu$ bond length of $1.504 \AA$ in $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ is longer than the average B-H $\mu$ bond length of $1.174 \AA$-too long to be explained by the greater tetrahedral covalent radius of beryllium vs. that of boron ( 1.06 vs. $0.88 \AA$, respectively). ${ }^{14} \mathrm{This} \mathrm{Be}-\mathrm{H} \mu$ vs. $\mathrm{B}-\mathrm{H} \mu$ bond length difference may result from the greater positive charge on the beryllium atom compared to that on the boron atom. The dihedral angle between the planes $\mathrm{H}(7)-\mathrm{Be}-\mathrm{H}(8)$ and $\mathrm{H}\left(7^{\prime}\right)-\mathrm{Be}-\mathrm{H}\left(8^{\prime}\right)$ is $91.6(8)^{\circ}$, within $2 \sigma$ of the ideal $90^{\circ}$ dihedral angle for a tetrahedral atom. Note, however, that the six $\mathrm{H}-\mathrm{Be}-\mathrm{H}$ angles range from 98.7 to $125.2^{\circ}$, quite different from the ideal $109.5^{\circ}$. The average $\mathrm{Be}-\mathrm{B}$ distance in

[^0]$\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ is $1.974 \AA$ while in the polymeric $\mathrm{Be}\left(\mathrm{BH}_{4}\right)_{2}$ the average $\mathrm{Be}-\mathrm{B}$ distances are 1.92 and $2.00 \AA$, with the beryllium atom six-coordinate and approximately trigonal prismatic. ${ }^{5}$

Molecular orbital calculations for $\mathrm{B}_{3} \mathrm{H}_{8}^{-15}$ and $(\mathrm{CO})_{4} \mathrm{CrB}_{3} \mathrm{H}_{8}-16$ indicate that the unique boron atom, $\mathrm{B}(2)$, is more positive than $\mathrm{B}(1)$ and $\mathrm{B}(3)$. Thus, the observation that the relatively positively charged $\mathrm{B}-\mathrm{H}-\mathrm{B}$ bridge hydrogen atoms are closer to $\mathrm{B}(1)$ and $\mathrm{B}(3)$ in all known octahydrotriborate complexes comes as no surprise.

Table VI compares bond lengths and bond angles in $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ to the analogous bond lengths and bond angles in other octahydrotriborate species. Bonding around the metal-$B(1)-B(3)$ region of the molecule, as expected, shows the largest variances when molecules are compared. Thus, $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ and $\left(\mathrm{Ph}_{3} \mathrm{P}_{2} \mathrm{CuB}_{3} \mathrm{H}_{8}\right.$ show better agreement in the metal- $\mathrm{B}(1)-\mathrm{B}(3)$ region of the molecule than $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ and $(\mathrm{CO})_{4} \mathrm{CrB}_{3} \mathrm{H}_{8}{ }^{-}$, since chromium has a higher coordination number. Note that the closest overall agreement in bond distances and angles occurs when $\mathrm{Be}\left(\mathrm{B}_{3} \mathrm{H}_{8}\right)_{2}$ is compared to $\mathrm{B}_{4} \mathrm{H}_{10}$, an anticipated result based on the similar coordination, bonding, and size of beryllium and boron.
