# Kinetic Studies on 1:1 Electron-Transfer Reactions Involving Blue Copper Proteins. 1. Evidence for an Unreactive Form of the Reduced Protein ( $\mathrm{pH}<5$ ) and for Protein-Complex Association in Reactions of Parsley (and Spinach) Plastocyanin 

Michael G. Segal and A. Geoffrey Sykes*<br>Contribution from the Department of Inorganic and Structural Chemistry, The University, Leeds LS2 9JT, England. Received October 2I, I977

#### Abstract

Reactions involving the $1: 1$ oxidation of reduced parsley plastocyanin, $\mathrm{PCu}(1)$, with $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}, \mathrm{Co}(\mathrm{bpy})_{3}{ }^{3+}$. and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$, and reduction of the blue $\mathrm{PCu}(11)$ with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}, \mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Py}^{2+}$, and $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}$, have been investigated, $I=0.10 \pm 0.01 \mathrm{M}(\mathrm{NaCl})$, by the stopped-flow method. Whereas overall rate constants for reactions of $\mathrm{PCu}(11)$ with $\mathrm{Fe}-$ $(\mathrm{CN})_{6}{ }^{4-}$ show little variation (ca. $30 \%$ increase) on decreasing the pH from 7 to 5 , there is a dramatic decrease for reactions of $\mathrm{PCu}(1)$ with all three oxidants corresponding to rapid (reversible) formation of a redox-inactive protonated form of the protein with acid dissociation constants, $\mathrm{p} K_{\mathrm{a}}$, in the range 5.7-6.1. Protonation at or near to the $\mathrm{Cu}(1)$ site seems likely. Overall activation parameters, $\mathrm{pH}>7$, were determined for all but the $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}$ reaction, and in two cases it was possible to extend the range of complex concentrations sufficiently for (kinetic) detection of protein-complex association ( $K$ ) prior to electron transfer ( $k_{\text {et }}$ ). These were the reactions: $\mathrm{PCu}(1)+\mathrm{Co}(\text { phen })_{3}{ }^{3+}$, where at $25^{\circ} \mathrm{C}, K=167 \mathrm{M}^{-1}, \Delta H^{\circ}=10 \mathrm{kcal} \mathrm{mol}^{-1}, ~ \Delta S^{\circ}$ $=45 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}, k_{\mathrm{el}}=17.9 \mathrm{~s}^{-1}, \Delta H_{\mathrm{el}} \ddagger=4.3 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta S_{\mathrm{el}} \ddagger=-39 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$; and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}+\mathrm{PCu}(\mathrm{II}), K=$ $110 \mathrm{M}^{-1}, \Delta H^{\circ}=-5.1 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta S^{\circ}=-7.8 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}, k_{\mathrm{e} 1}=170 \mathrm{~s}^{-1}, \Delta H_{\mathrm{el}} \neq 11.4 \mathrm{kcalmol}^{-1}, \Delta S_{\mathrm{el}} \neq-9.7 \mathrm{cal} \mathrm{K}^{-1}$ $\mathrm{mol}^{-1}$. Comparisons with previous data for the temperature-jump equilibration study of azurin $\mathrm{ACu}(1) / \mathrm{ACu}(11)$ with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-} / \mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ are made. Possible limitations imposed by consideration of overall kinetic parameters without reference to $K$ and $k_{\text {et }}$ are to be stressed. From ionic strength dependences and values of $\Delta H^{\circ}$ and $\Delta S^{\circ}$ as above the protein behaves as a negatively charged species, but it is not clear whether this corresponds to the charge at the binding site. A similar dependence on pH and evidence for association were obtained in the $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}$ oxidation of spinach plastocyanin.

Plastocyanin is a blue copper (type 1) protein which is found in plant chloroplasts and other photosynthetic organisms. ${ }^{1}$ It is an essential component in the photosynthetic elec-tron-transport chain making use of the blue $\mathrm{Cu}(\mathrm{II})$ and colorless $\mathrm{Cu}(\mathrm{I})$ states. ${ }^{2}$ While earlier papers have indicated that there are 2 Cu atoms per protein it has now been demonstrated ${ }^{3.4}$ that there is only a single Cu atom per unit of molecular weight ca. 10500 . The Cu is bound in a distorted tetrahedral ligand environment, ${ }^{5}$ which is not accessible to solvent $\mathrm{H}_{2} \mathrm{O} .{ }^{6}$ Plastocyanins from different plant sources show only minor differences in amino acid composition and sequencing. ${ }^{3,4}$ An isoelectric point is observed at pH ca. 4.2,7 and at higher pH s the protein becomes appreciably negatively charged. Standard reduction potentials have been determined and are ca. $360 \mathrm{mV}{ }^{8,9}$

As a means of understanding more fully features of the electron-transfer process involving such metalloproteins, reactions of parsley and (to a lesser extent) spinach plastocyanin have been investigated, and are reported herein. Comparisons with studies involving the blue copper protein azurin from bacterial sources are made. The abbreviations $\mathrm{PCu}(\mathrm{I}) / \mathrm{PCu}(\mathrm{II})$ and $\mathrm{ACu}(\mathrm{I}) / \mathrm{ACu}(\mathrm{II})$ are used to indicate different oxidation states of plastocyanin and azurin, respectively.

## Experimental Section

Proteins. Plastocyanin was isolated from parsley leaves by the method of Plesničar and Bendall. ${ }^{10}$ After preparation the parsley leaves were stored at ca. $-15^{\circ} \mathrm{C}$ for a minimum time (generally overnight) before use. The final stage in the procedure described, involving concentration of the protein, was omitted. The yield of $\mathrm{PCu}(\mathrm{II})$ was $20-40 \mathrm{~mL}$ of $(4-6) \times 10^{-5} \mathrm{M}$ solution from 2.5 kg of cut leaves. This gave an absorbance $(A)$ ratio at peak positions $A_{278} / A_{597}$ of 1.7 $\pm 0.1$, in good agreement with previous determinations. ${ }^{8}$ The spectrum based on $\epsilon=4.5 \times 10^{3} \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ at $597 \mathrm{~nm}^{7.8}$ is as shown in Figure 1. Concentrations were determined from the absorbance at 597 nm . No significant ( $\pm 5 \%$ ) variation in kinetic parameters was observed using samples from different batches. Before use the protein solution was dialyzed (Sigma $21-\mathrm{mm}$ dialysis sacks) against the required buffer
for $24 \mathrm{hat} \mathrm{ca} .0^{\circ} \mathrm{C}$. To obtain the reduced form. $\mathrm{PCu}(1)$, a few crystals of sodium dithionite (G.P.R. grade, B.D.H.), representing an excess of this reductant, were added before dialysis. Reduction is known to be rapid. ${ }^{8}$ The reduced form has the same UV spectrum but no visible absorption.

Spinach plastocyanin was extracted from spinach leaves by the literature method. ${ }^{11}$ After removal of ferredoxin as described, the 0.2 $\mathrm{M} \mathrm{Cl}^{-}$eluate of the first DEAE-cellulose (Whatman Ltd.) column was diluted $2 \times$, loaded onto a column of DE23 cellulose ( 7 cm long, 5 cm diameter), and washed with 0.05 M sodium phosphate buffer ( pH 6.9 ) and the plastocyanin $\mathrm{PCu}(\mathrm{I})$ was eluted with a 0.1 M solution of the same buffer. The protein was purified in the same way as for parsley on further columns of DEAE-cellulose. The spectrum is very similar to that of parsley, Figure 1, peak ratio $a_{278} / A_{597}=1.69$. Spectra are compared with those of other blue Cu proteins in Table 1.

Complexes. Tris(1,10-phenanthroline)cobalt(III) was prepared as the perchlorate salt, $\left[\mathrm{Co}(\text { phen })_{3}\right]\left(\mathrm{ClO}_{4}\right)_{3} \cdot 2 \mathrm{H}_{2} \mathrm{O},{ }^{12}$ which was percipitated out of solution by addition of saturated $\mathrm{NaClO}_{4}$, and recrystallized from $\mathrm{H}_{2} \mathrm{O}$ with the addition of a few drops of 5 M $\mathrm{HClO}_{4}$. Peak positions $\left[\lambda, \mathrm{nm}\left(\epsilon, \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)\right]$ were at $330(4660)$, 350 (3620), and 450 (100) in good agreement with literature values. The chloride salt, $\left[\mathrm{Co}(\mathrm{phen})_{3}\right] \mathrm{Cl}_{3} \cdot 7 \mathrm{H}_{2} \mathrm{O},{ }^{13}$ was also used when the perchlorate salt was not sufficiently soluble. Replacement of $\mathrm{Cl}^{-}$by $\mathrm{ClO}_{4}{ }^{-}$was shown to have no effect on rate constants (see e.g., Table III of the microfilm edition; see paragraph at end of paper). Tris( $2,2^{\prime}$-bipyridine) cobalt(III), $\left[\mathrm{Co}(\text { bpy })_{3}\right]\left(\mathrm{ClO}_{4}\right)_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$, was prepared, ${ }^{14}$ and gave a spectrum with peak positions $\left[\lambda, \mathrm{nm}\left(\epsilon, \mathrm{M}^{-1}\right.\right.$ $\left.\mathrm{cm}^{-1}\right)$ ] at 306 (34 100), 317 (30700), and 450 (68.4) in agreement with previous values. Potassium hexacyanoiron(111), $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}$ (B.D.H, AnalaR), peak at 300 ( 1600 ) and 420 ( 1010 ), and potassium hexacyanoiron( II ), $\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (Hopkin and Williams, AnalaR), peak 330 (330), were used as supplied. Solutions of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ were used soon after preparation, i.e. within 30 min , or alternatively were stored under $\mathrm{N}_{2}$. When this precaution was not observed significant air oxidation occurred, and there was an increase in experimentally determined rate constant due to formation of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$. Hexaammineruthenium(111) chloride, $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$, was obtained from Johnson and Matthey and purified by the literature method. ${ }^{15}$ Aqueous solutions ( $1-5$ ) $\times 10^{-4} \mathrm{M}$ were reduced (ca. $75 \%$ conversion at neutral pH ) on an amalgamated zinc shot column ( 20

Table I. A Comparison of Visible Spectra $\left[\lambda(\mathrm{nm}), \epsilon\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)\right]$ of Blue Copper Proteins, Oxidized From $\mathrm{Cu}(\mathrm{II})$, in Aqueous Solution, $\mathrm{pH} \sim 7$

${ }^{a}$ This work; see also ref 7 and $8 .{ }^{b}$ R. Malkin and B. G. Malmström, Adv. Enzymol., 33, 177 (1970). The protein unit is assumed to contain 1 Cu (mol wt 10500 ). Azurin $\epsilon$ values as in ref 32 .

Fígure 1. UV-visible spectrum of parsley plastocyanin $\mathrm{PCu}(\mathrm{II})$ in aqueous solution, pH 7 . The reduced form $\mathrm{PCu}(1)$ has the same spectrum, $<300$ nm.
cm long, 2 cm diameter) under argon gas, immediately prior to use. Concentrations were determined by reacting with $\mu$-superoxobis[pentaamminecobalt(1I1)], when there is a rapid $1: 1$ reaction, and measuring the absorbance change at $670 \mathrm{~nm}\left(\epsilon 890 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$. Crystalline pyridinopentaammineruthenium(II) perchlorate, $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}\right]\left(\mathrm{ClO}_{4}\right)_{2}$, was prepared by the literature method, ${ }^{16}$ starting from $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$. Peak positions $\left.\lambda, \mathrm{nm}\left(\epsilon, \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)\right]$ were at $244\left(4.8 \times 10^{3}\right)$ and $407\left(7.24 \times 10^{3}\right)$.

Buffers. Solutions were prepared from mono- and disodium hydrogen phosphates, hydrochloric acid, sodium acetate, and acetic acid (all AnalaR, B.D.H.), sodium cacodylate, $\mathrm{Na}\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{AsO}_{2}\right]$ (Laboratory Reagent, B.D.H.), and tris(hydroxymethyl)aminomethane (Trizma) here referred to as Tris (Sigma Chemicals). For experiments in which the pH variation was investigated, $10^{-2} \mathrm{M}$ sodium cacodylate, pH adjusted to $5.0-7.5$ by addition of HCl , was used. Tris was added to $2 \times 10^{-3} \mathrm{M} \mathrm{HCl}$ to give solutions $\mathrm{pH} 7.0-9.0$, and $5 \times 10^{-3}$ M sodium acetate with HCl was used to obtain a pH of 4.3. Rate constants in Tris were found to be $20 \%$ higher than those in cacodylate for the region where the pH ranges overlapped (see, e.g., Table $1 \mathrm{X}^{23}$ ). To investigate complex concentration dependencies, and for the determination of activation parameters, $10^{-2} \mathrm{M}$ sodium phosphate $\left(\mathrm{Na}_{2} \mathrm{HPO}_{4}+\mathrm{NaH}_{2} \mathrm{PO}_{4}\right)$ pH 7.0 or 7.5 was used. Cacodylate was also used to check concentration dependence at pH 5.0. Rate constants in phosphate were also $10-20 \%$ higher than those in cacodylate. For ionic strength variations $10^{-3} \mathrm{M}$ phosphate buffer was used.

Redox Potentials. The standard reduction potential for the $\mathrm{PCu}(11) / \mathrm{PCu}(1)$ couple is 0.36 V at $\mathrm{pH} 7.5 .^{6}$ The high reactivity of the protein permitted only a narrow range of redox reagents to be investigated. Reduction potentials for complexes used are: Co(phen) $3^{3+} / \mathrm{Co}($ phen $) 3^{2+}(0.37 \mathrm{~V}),{ }^{12} \mathrm{Co}($ bpy $) 3^{3+} / \mathrm{Co}(\text { bpy })_{3}{ }^{2+}(0.37$ V), ${ }^{18} \mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-} / \mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\left(0.41 \quad\right.$ V), ${ }^{19} \quad \mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{3+} /$ $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{2+}(0.253$ and 0.273 in ref 17 , but 0.310 in ref 20 ), $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+} / \mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}(0.051 \mathrm{~V}) .{ }^{20}$

Stoichiometry. Potential measurements of Katoh et al. ${ }^{9}$ have indicated a one-electron transfer in the redox equilibration of spinach plastocyanin with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-} / \mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$. An equilibrium constant of 5.0 determined from rate constants for $\mathrm{PCu}(\mathrm{I})+\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ and
$\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}+\mathrm{PCu}(\mathrm{II})$ (present study) is in good agreement with a value of ca. 7 obtained from redox potentials, thus supporting a oneelectron reaction. McArdle et al. ${ }^{21}$ have previously studied the oxidation of $\mathrm{PCu}(1)$ with $\mathrm{Co}(\text { phen })_{3}{ }^{3+}$ and analyzed their data in terms of a $1: 1$ reaction. Spectrophotometric titration of $\mathrm{PCu}(1)$ with $\mathrm{Co}-$ (phen) $3^{3+}$ indicated a $1: 1$ reaction with an equilibrium constant for $\mathrm{PCu}(1)+\mathrm{Co}(\text { phen })_{3}{ }^{3+} \rightleftharpoons \mathrm{PCu}(\mathrm{I} 1)+\mathrm{Co}(\mathrm{phen}) 3^{2+}$ of 1.6 in close agreement with the electrode potentials quoted above, pH 7.0 (phosphate), $I=0.10 \mathrm{M}(\mathrm{NaCl})$.

Kinetic Studies. lonic strengths ( $I$ ) were adjusted to 0.10 M using NaCl . For reactions in $10^{-2} \mathrm{M}$ sodium phosphate at pH 7.0 we have followed Wood ${ }^{8}$ in using 0.09 M NaCl . With the phosphate contribution this yields a total ionic strength of ca. 0.108 M . Reactions were monitored using a Durrum stopped-flow spectrophotometer. Traces were photographed from a Tektronix storage oscilloscope, where at least two traces were analyzed for each run (agreement $\pm 5 \%$ ). We attempted to study the equilibration of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ with $\mathrm{PCu}(11)$ by temperature-jump techniques, but encountered stability problems with the protein, which was decolorized after a series of jumps. Instead it was found that the reactions of $\mathrm{PCu}(1)$ with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$, and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ with $\mathrm{PCu}(I I)$, could be studied independently by the stopped-flow method by having reactants $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ ( $>$ tenfold) and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ ( $>30$-fold), respectively, in excess. In all experiments the formation or decay of the blue Cu protein absorbance at the $597-\mathrm{nm}$ was monitored with time. Plots of $\log \Delta A$ against time were linear for at least 3 half-lives. First-order rate constants were obtained from slopes ( $\times 2.303$ ). Air-free conditions (Ar gas) were necessary for the $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{2+}$ and $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}$ studies. The latter reduction is very rapid and had to be studied under second-order conditions with $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\right]=(1-6) \times 10^{-6} \mathrm{M}$ and $[\mathrm{PCu}(1 \mathrm{I})]=(7-10) \times 10^{-6}$ M to obtain meaningful traces. Under these conditions rate constants obtained were lacking in precision and only an approximate rate constant is indicated.

Treatment of Data. A nonlinear least-squares program ${ }^{22}$ and subroutines based on this were used. Weighting factors were in all cases equivalent to $1 / y^{2}$. For computation of data in connection with eq 1 , $k_{0}, k_{\mathrm{H}}$, and $K_{\mathrm{H}}$ were independent variables; with eq $7, \Delta H^{\circ}, \Delta S^{\circ}$ (for $K$ ), $\Delta H_{\mathrm{el}} \neq$, and $\Delta S_{\mathrm{eI}} \neq$ (for $k_{\mathrm{et}}$ ) were independent variables.

## Results

Parsley plastocyanin was used throughout except for the oxidation of $\mathrm{PCu}(\mathrm{I})$ with CO (phen) $3^{3+}$ when the reaction ( 25 ${ }^{\circ} \mathrm{C}$ ) with spinach plastocyanin was also studied.

Oxidation of $\mathrm{PCu}(\mathbf{I})$ with $\mathrm{Co}(\text { phen })_{3}{ }^{3+}$. Second-order rate constants, $k$, for the reactions of both parsley and spinach plastocyanin with $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}\left(<5 \times 10^{-4} \mathrm{M}\right)$ are dependent on $\left[\mathrm{H}^{+}\right]$for the pH range $5.0-7.5$, Table $\mathrm{II}^{23}$. The dependence, Figure 2, is of the form:

$$
\begin{equation*}
k=\frac{k_{0}+k_{\mathrm{H}} K_{\mathrm{H}}\left[\mathrm{H}^{+}\right]}{1+K_{\mathrm{H}}\left[\mathrm{H}^{+}\right]} \tag{1}
\end{equation*}
$$

where the constants are as defined in eq 2-4:

$$
\begin{gather*}
\mathrm{PCu}(\mathrm{I})+\mathrm{H}^{+} \stackrel{K_{\mathrm{H}}}{\rightleftharpoons} \mathrm{HPCu}(\mathrm{I})  \tag{2}\\
\mathrm{PCu}(\mathrm{I})+\mathrm{Co}(\text { phen })_{3}{ }^{3+} \xrightarrow{k_{0}} \text { products }  \tag{3}\\
\mathrm{HPCu}(\mathrm{I})+\mathrm{Co}(\text { phen })_{3}{ }^{3+} \xrightarrow{k_{\mathrm{H}}} \text { products } \tag{4}
\end{gather*}
$$

A least-squares best fit to eq 1 gives a small negative value to

Figure 2. The variation of rate constants $\left(25^{\circ} \mathrm{C}\right)$ for the $\mathrm{Co}(\mathrm{phen}) 3_{3}{ }^{3+}$ oxidation of parsley and spinach $\mathrm{PCu}(\mathrm{I})$ with $\mathrm{pH}, I=0.10 \mathrm{M}(\mathrm{NaCl})$.

Table IV. Dependence of First-Order Rate Constants ( $25^{\circ} \mathrm{C}$ ) for the Oxidation of $\mathrm{PCu}(\mathrm{I})$ Spinach Plastocyanin ( $10^{-5} \mathrm{M}$ ) with $\mathrm{Co}(\mathrm{phen}) 3^{3+}$ on Concentration of Oxidant (pH 7.5 Sodium Cacodylate/ HCl Buffer, $I=0.10 \mathrm{M}(\mathrm{NaCl})$ )

| $\left.10^{3}[\mathrm{Co(phen}) 3^{3+}\right]$, <br> $\mathbf{M}$ | $k_{\text {obsd }}$, <br> $\mathbf{s}^{-1}$ | $10^{3}\left[\mathrm{Co}(\right.$ phen $\left.) 3^{3+}\right]$, <br> $\mathbf{M}$ | $k_{\text {obsd }}$ <br> $\mathbf{s}^{-1}$ |
| :---: | :---: | :---: | :---: |
| 0.20 | 1.16 | 1.00 | 4.78 |
| 0.30 | 1.77 | 2.00 | 6.95 |
| 0.40 | 2.31 | 3.00 | 9.40 |
| 0.60 | 3.14 | 4.00 | 10.0 |

$k_{\mathrm{H}}$. We have therefore fixed this parameter at zero which then yields $K_{\mathrm{H}}=(1.27 \pm 0.11) \times 10^{6} \mathrm{M}^{-1}$ and $k_{0}=(2.69 \pm 0.15)$ $\times 10^{3} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ for parsley $\mathrm{PCu}(\mathrm{I})$. For spinach plastocyanin, $K_{\mathrm{H}}=\sim 5 \times 10^{5} \mathrm{M}^{-\left[=K_{]}\right.}=\sim 5.9 \times 10^{3} \mathrm{M}^{-1} \mathrm{~s}^{-1}$. Attempts to monitor the reactions at pH 4.3 (acetate buffer) by the same stopped-flow method failed due to the slowness of the redox process. The parsley protein was held at pH 5 for several hours and the reactivity to oxidation fully restored on raising the pH . Both the protonation and deprotonation processes are rapid relative to the redox step, and cannot be observed on the stopped-flow time scale.

By extending the range of $\left[\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}\right]$ to $(0.1-4.8) \times$ $10^{-3} \mathrm{M}$ at pH 7.5 under which condition $\mathrm{PCu}(\mathrm{I})$ is deprotonated and $k=k_{0}$, a nonlinear dependence of first-order rate constant $k_{\text {obsd }}$ on oxidant is observed. Plots of $k_{\text {obsd }}{ }^{-1}$ against $\left[\mathrm{Co}(\mathrm{phen}) 3^{3+}\right]^{-1}$ are linear, as illustrated in Figure 3, which is consistent with a reaction sequence (eq 5 and 6):

$$
\begin{gather*}
\mathrm{PCu}(\mathrm{I})+\mathrm{Co}(\text { phen })_{3}{ }^{3+} \stackrel{K}{\rightleftharpoons} \mathrm{PCu}(\mathrm{I}),(\mathrm{Co} \text { phen })_{3}{ }^{3+}  \tag{5}\\
\mathrm{PCu}(\mathrm{I}), \mathrm{Co}(\text { phen })_{3}{ }^{3+} \xrightarrow{k_{\mathrm{el}}} \mathrm{PCu}(\mathrm{II})+\mathrm{Co}(\text { phen })_{3}{ }^{2+} \tag{6}
\end{gather*}
$$

and a dependence as in eq 7 :

$$
\begin{equation*}
k_{\text {obsd }}=\frac{k_{\mathrm{e} 1} K\left[\mathrm{Co}(\text { phen })_{3}{ }^{3+}\right]}{1+K\left[\mathrm{Co}(\text { phen })_{3}{ }^{3+}\right]} \tag{7}
\end{equation*}
$$

The temperature was varied $10.8-31.1^{\circ} \mathrm{C}$ for parsley and a least-squares fit of data in Table III gave $K\left(25^{\circ} \mathrm{C}\right)=167 \pm$ $20 \mathrm{M}^{-1}, \Delta H^{\circ}=10 \pm 3.5 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta S^{\circ}=45 \pm 11 \mathrm{cal} \mathrm{K}^{-1}$ $\mathrm{mol}^{-1}, k_{\mathrm{et}}\left(25^{\circ} \mathrm{C}\right)=17.9 \pm 1.7 \mathrm{~s}^{-1}, \Delta H_{\mathrm{et}}{ }^{\ddagger}=4.3 \pm 2.9 \mathrm{kcal}$
 IV, data at $25^{\circ} \mathrm{C}$ gave $K=389 \pm 25 \mathrm{M}^{-1}$ and $k_{\mathrm{et}}=16.7 \pm$ $0.8 \mathrm{~s}^{-1}$. The dependence of $k$ for parsley on ionic strength was investigated (see Table V). ${ }^{23}$

Oxidation of $\mathrm{PCu}(\mathrm{I})$ with $\mathrm{Co}(\text { bpy })_{3}{ }^{3+}$. The dependence of second-order rate constants on pH (Table VI) exhibited more

Figure 3. The linear dependence of reciprocal first-order rate constants for the $\mathrm{Co}(\text { phen })_{3}{ }^{3+}$ oxidation of parsley $\mathrm{PCu}(\mathrm{I})$ on $\left[\mathrm{Co}(\mathrm{phen}) 3^{3+}\right]^{-1}$ at $\mathrm{pH} 7.5, I=0.10 \mathrm{M}(\mathrm{NaCl})$.

Table VI. Dependence of Rate Constant $k\left(25^{\circ} \mathrm{C}\right)$ on pH for the Oxidation of $\mathrm{PCu}(1)$ Parsley Plastocyanin ( $10^{-5} \mathrm{M}$ ) with $\mathrm{Co}-$ (bpy) $3^{3+}\left(6.0 \times 10^{-4} \mathrm{M}\right)\left(10^{-2} \mathrm{M}\right.$ Sodium Cacodylate $/ \mathrm{HCl}$ Buffer, $I=0.10 \mathrm{M}(\mathrm{NaCl}))^{a}$

${ }^{a}$ The plastocyanin was kept at pH 7.5 prior to mixing. ${ }^{b}$ Protein was stored at pH 5.0 prior to mixing. The small difference in $k$ is possibly due to different degrees of association of protein with buffer. c $2 \times 10^{-3} \mathrm{M} \mathrm{HCl}+$ Tris .
complicated behavior than for $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}$. The sigmoidal shape, $\mathrm{pH}<6.5$, originates from reaction steps as in eq 2 and 3 , and gives $K_{\mathrm{H}}=\sim 9.7 \times 10^{5} \mathrm{M}^{-1}$ and $k_{0}=\sim 390 \mathrm{M}^{-1} \mathrm{~s}^{-1}$. The further increase in rate constants at higher pH values is believed to stem from side reactions of the oxidant. ${ }^{24}$ Aquation of the complex contributes at $\mathrm{pH}>7.5$. Rate constants, $k$, at pH 7 (Table VII) give an estimate for $k_{0}$. A least-squares fit of data at $\mathrm{pH} 7,10.0-29.6^{\circ} \mathrm{C}$, gives $k\left(25^{\circ} \mathrm{C}\right)=322 \mathrm{M}^{-1} \mathrm{~s}^{-1}$, $\Delta H^{\ddagger}=9.7 \pm 4 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta S^{\ddagger}=-14.6 \pm 1.5 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$. On increasing the range of $\left[\mathrm{Co}(\mathrm{bpy})_{3}{ }^{3+}\right]$ to $4.0 \times 10^{-3} \mathrm{M}$ no evidence for association as in eq 5-6 was obtained. Table VIII gives the variation of $k$ with ionic strength. ${ }^{23}$

Oxidation of $\mathrm{PCu}(\mathrm{I})$ with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$. Second-order rate constants, $k$ (Table IX ${ }^{23}$ ) give a dependence on pH , Figure 4, similar to that for $\mathrm{Co}(\text { phen })_{3}{ }^{3+}$. A fit of data to the same type of reaction sequence yields $K_{\mathrm{H}}=(5.2 \pm 0.2) \times 10^{5} \mathrm{M}^{-1}, k_{0}$ $=(7.8 \pm 0.2) \times 10^{4} \mathrm{M}^{-1} \mathrm{~s}^{-1}$. The concentration of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ was increased to the limit possible for stopped-flow studies without being able to detect a less than first-order dependence on oxidant $\left[\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}\right.$ ]. It was not possible therefore to evaluate $K$ and $k_{\mathrm{ct}}$. From the temperature dependence $10.5-33.4^{\circ} \mathrm{C}$, Table X, $k\left(25{ }^{\circ} \mathrm{C}\right)=(9.4 \pm 0.4) \times 10^{4} \mathrm{M}^{-1}$ $\mathrm{s}^{-1}, \Delta H^{\ddagger}=-3.4 \pm 0.1 \mathrm{kcal} \mathrm{mol}{ }^{-1}$, and $\Delta S^{\ddagger}=-47 \pm 0.3 \mathrm{cal}$ $\mathrm{K}^{-1} \mathrm{~mol}^{-1}$. The variation of $k$ with $I$ was investigated (Table $\mathrm{XI}^{23}$ ).

Reduction of $\mathrm{PCu}(\mathrm{II})$ with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$. Only a small variation in rate constant $k$ with pH was observed, Figure 4 (Table

Figure 4. The variation of rate constants $\left(25^{\circ} \mathrm{C}\right)$ for the reactions of parsley plastocyanin $\mathrm{PCu}(\mathrm{I})+\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}(\bullet)$ and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}+\mathrm{PCu}(\mathrm{Il})$ (O) with $\mathrm{pH}, I=0.10 \mathrm{M}(\mathrm{NaCl})$.

XII ${ }^{23}$ ). On extending the range of $\left[\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\right]$ to $(0.3-2.0)$ $\times 10^{-3} \mathrm{M}$, first-order rate constants, $k_{\text {obsd }}\left(\right.$ Table XIII ${ }^{23}$ ), gave a nonlinear dependence on $\left[\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\right]$. Plots of $k_{\text {obsd }^{-1}}{ }^{-1}$ against $\left[\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\right]^{-1}$, Figure 5, are linear, consistent with the reaction sequence of eq 8 and 9 , which is similar to eq 5 and 6 :

$$
\begin{align*}
& \mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}+\mathrm{PCu}(\mathrm{II}) \stackrel{K}{\rightleftharpoons} \mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}, \mathrm{PCu}(\mathrm{II})  \tag{8}\\
& \mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}, \mathrm{PCu}(\mathrm{II}) \xrightarrow{k_{\mathrm{el}}} \mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}+\mathrm{PCu}(\mathrm{I}) \tag{9}
\end{align*}
$$

From a least-squares fit of data, $6.8-29.4^{\circ} \mathrm{C}, K\left(25^{\circ} \mathrm{C}\right)=110$ $\pm 30 \mathrm{M}^{-1}, \Delta H^{\circ}=-5.1 \pm 2.6 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta S^{\circ}=-7.8 \pm 9.0$ $\mathrm{cal} \mathrm{K}{ }^{-1} \mathrm{~mol}^{-1}, k_{\mathrm{et}}\left(25^{\circ} \mathrm{C}\right)=170 \pm 40 \mathrm{~s}^{-1}, \Delta H_{\mathrm{et}}{ }^{\mp}=11.4 \pm$ $2.3 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta S_{\mathrm{et}}{ }^{\ddagger}=-9.7 \pm 8.0 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$. The ionic strength dependence was also investigated (Table XIV ${ }^{23}$ ).

Reduction of $\mathrm{PCu}(\mathrm{II})$ with $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{2+}$ and $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{\mathbf{2 +}}$. Of prime interest was whether a nonlinear dependence on reductant could be detected. Unfortunately both reactions were too rapid for a sufficiently extensive range of reductant concentrations to be investigated. Overall activation parameters were obtained from studies on the reaction of $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{2+}$

Figure 5. The linear dependence of reciprocal first-order rate constants for the $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ reduction of parsley $\mathrm{PCu}(\mathrm{II})$ on $\left[\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}\right]$ at pH $7.0, I=0.108 \mathrm{M}(\mathrm{NaCl})$.

[^0]$\left(7.1-25^{\circ} \mathrm{C}\right)$, Table XV. These are $k\left(25^{\circ} \mathrm{C}\right)=(1.1 \pm 0.1) \times$ $10^{6} \mathrm{M}^{-1} \mathrm{~s}^{-1}, \Delta H^{\ddagger}=9.7 \pm 0.8 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta S^{\ddagger}=1.6 \pm 2.9$ cal $\mathrm{K}^{-1} \mathrm{~mol}^{-1}$. Rate constants for the $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}$ reduction of PCu (II) at $5{ }^{\circ} \mathrm{C}$ were ca. $2.4 \times 10^{6} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ in Tris buffer ( pH 7.0 ).

## Discussion

Gray and coworkers ${ }^{25}$ have previously investigated the effect of pH on the $\mathrm{Fe}(\mathrm{edta})^{2-}$ reduction of bean $\mathrm{PCu}(\mathrm{II})$ and found there to be a (relatively) small effect in the range $\mathrm{pH} 5-8$. For the oxidation of $\mathrm{PCu}(\mathrm{I})$ no similar investigation of pH has been reported. A similar dependence to that for PCu (II) would be consistent with the report by Katoh et al. ${ }^{9}$ that the reduction potential for spinach $\mathrm{PCu}(\mathrm{II}) / \mathrm{PCu}(\mathrm{I})$ is invariant until pH <5.4. In accordance with Gray ${ }^{25}$ we find that for the reduction of $\mathrm{PCu}(\mathrm{II})$ with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ there is only a mild (30\%) increase in rate constant with a decrease in the pH from 7 to 5 . Our data do not give a sigmoidal shape, Figure 4, and we have not attempted, therefore, to calculate a protonation constant $K_{\mathrm{H}}$. It is not clear to us that the case for a single protonation step has been clearly established.

The effect of pH on the oxidation of $\mathrm{PCu}(\mathrm{I})$ by $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$, $\mathrm{Co}(\mathrm{phen}) 3^{3+}$, and $\mathrm{Co}(\mathrm{bpy}) 3^{3+}$ has now been investigated, and a quite dramatic variation in rate constants is observed. Comparisons of parsley and spinach plastocyanin with Co-

(phen) $3^{3+}$ as oxidant indicate analogous pH behavior, and in view of the similar physical properties of plastocyanins from a wide range of sources, ${ }^{1}$ we have no reason to suspect that the effects observed for parsley plastocyanin are nontypical. The pH dependence was investigated with oxidant concentrations at the lower end of the range employed, under which condition reactions conform to rate laws first order in oxidant. Although a complication is observed with $\mathrm{Co}(\mathrm{bpy})_{3}{ }^{3+}$ at $\mathrm{pH}>7$, the behavior can otherwise be satisfactorily accounted for in terms of a simple protonation as in eq 2 with the protonated form redox inactive. Rate constants for the $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ oxidation of $\mathrm{PCu}(\mathrm{I})$ decrease from $7.9 \times 10^{4} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ at $\mathrm{pH}>7$ to zero at $\mathrm{pH}<5$. The effects do not correspond to a denaturing of the protein. Thus, after storing at pH 5.0 for several hours the reactivity to oxidation is fully restored on raising the pH . Both the protonation and deprotonation are rapid relative to the redox steps and could not be observed on the stopped-flow time scale. When different buffers are used only small differences are observed. Thus, rate constants obtained in $10^{-2} \mathrm{M}$ phosphate and Tris buffers are in very good agreement, but rate constants determined in cacodylate buffer give rate constants ca. $20 \%$ less. Differences in $k_{0}$ as determined in cacodylate buffer and $k$ determined in phosphate at $\mathrm{pH} \geqslant 7$ are apparent therefore. The pH profiles, Figures 2 and 4 , give $\mathrm{p} K_{\mathrm{a}}$ values $\left(K_{\mathrm{a}}=1 / K_{\mathrm{H}}\right)$ of 6.1 and 5.7 with $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}$ and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$, respectively, as oxidants. The difference in these values is sufficiently large as to prompt the question whether binding of the oxidant to the protein prior to electron transfer may influence the protonation which then becomes dependent on the identity of the oxidant. Further studies are required for confirmation of this possibility. The quite different pH profiles observed for $\mathrm{PCu}(\mathrm{I})$ and $\mathrm{PCu}(\mathrm{II})$, Figure 4 , clearly require the reduction potential to vary with pH . Values of the electrode potential, $E^{\circ}$, at different pH values have been calculated from the kinetically determined equilibrium constant obtained from rate constants $k$ for the reactions $\mathrm{PCu}(\mathrm{I})+\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ and $\mathrm{PCu}(\mathrm{II})+\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$. These are shown in Figure 6. The results obtained by Katoh et al. ${ }^{9}$ for spinach plastocyanin by static equilibrium measurements are also shown for comparison. Their observations indicate a $\mathrm{p} K_{\mathrm{a}}$ value of ca. 5.4 in the presence of a mixture of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-} / \mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$.

There are three ways whereby the protonation of the protein may render it inactive: (i) by preventing the binding of oxidant to the protein surface; (ii) by preventing electron transfer between the bound oxidant and the protein redox site; (iii) by making the copper ion redox inactive. The absence of a major pH effect on the reactivity of PCu (II) indicates that protonation occurs at a site greatly affected by the copper oxidation state, and so at or near the Cu coordination sphere. Further studies are in progress to determine the effects of pH on $K$, (i) above, and $k_{\mathrm{et}}$, (ii) and (iii) above.

It is possible that protonation of an amino acid close to the Cu could induce a change in coordination sufficient to account

Figure 6. The variation of reduction potential for the $\mathrm{PCu}(11) / \mathrm{PCu}(1)$ couple with pH . Points ( ) are as derived from kinetic data for the respective reactions with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$. The line drawn deviates from these points at low pH assuming that the $\mathrm{PCu}(11)+\mathrm{Fe}-$ $(\mathrm{CN})_{6}{ }^{3-}$ reaction is independent of pH and that the rale constant pH 7 applies. The points ( $O$ ) are taken from Katoh et al. (ref 9).
for the above effect. However, an alternative explanation which we find attractive is that addition of a proton may bring about dissociation of a ligand from the metal. Crystallographic evidence for coordination of the Cu to one cysteinyl sulfur, two histidine nitrogens, and one methionine at a distorted tetrahedral site $6 \AA$ from the surface of the protein has been obtained. ${ }^{5}$ In the absence of a crystallographic study the same structure is assumed to apply for $\mathrm{PCu}(\mathrm{I})$, which is in keeping with the extremely efficient interconversion of $\mathrm{PCu}(\mathrm{I})$ and $\mathrm{PCu}(\mathrm{II})$ at $\mathrm{pH} \geqslant 7$ involving minimal reorganizational requirements. A distorted tetrahedral geometry is believed to be acceptable to both oxidation states. ${ }^{27}$ From its coordination chemistry $\mathrm{Cu}(\mathrm{I})$ exhibits 2,3 , and 4 (tetrahedral) coordination. Coordination numbers of $3^{28}$ and $4^{29}$ are only generally acceptable, however, in the presence of $\Pi$-acceptor ligands in view of the $3 \mathrm{~d}^{10}$ configuration. Dissociation of the methionine ligand would not involve a proton since the sulfur atom remains unprotonated. Retention of the cysteine ligand as a stabilizing influence seems likely. From NMR studies protonation of the two histidines of $\mathrm{PCu}(\mathrm{I})$ has been reported with $\mathrm{p} K_{\mathrm{a}}$ values of 4.9 and $<4.5 .{ }^{30}$ If ligand dissociation occurs we feel that this is most probably a histidine where it is of course possible that the $\mathrm{p} K_{\mathrm{a}}$ has been shifted to a higher value by the presence of oxidant. We have been unable to test the possibility of a change in coordination number in terms of variations in spectra because $\mathrm{PCu}(\mathrm{I})$ has no visible absorbance, and the spectrum $<300 \mathrm{~nm}$, which is the same as for PCu (II) (Figure 1), is probably not helpful in diagnosing a change in geometry.

If a $\mathrm{PCu}(\mathrm{I})$ species of decreased coordination number is formed then it is possible that other species in solution might under favorable circumstances coordinate to the metal, thus hindering rapid re-formation of reactive $\mathrm{PCu}(\mathrm{I})$ on increasing the pH . This possibility was tested for at $25^{\circ} \mathrm{C}$ in $10^{-2} \mathrm{M}$ cacodylate buffer, $I=0.10 \mathrm{M}(\mathrm{NaCl})$, by addition of NaSCN $\left(10^{-2} \mathrm{M}\right)$ which was found to have negligible ( $<10 \%$ ) effect on the $\mathrm{Co}(\text { phen })_{3}{ }^{3+}$ and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ oxidation of $\mathrm{PCu}(\mathrm{I})$ at pH 5. The thiocyanate was added to the protein solution 1-2 h before mixing on the stopped flow. These experiments are consistent with the Cu site being inaccessible to the aqueous environment even when the protein is protonated.

It should be emphasized in the context of pH variation that for $\left[\mathrm{H}^{+}\right]$dependencies of the type observed, eq 1 , ambiguities do exist in the interpretation. According to the treatment of Newton and Baker, ${ }^{31}$ alternative mechanisms besides those indicated in eq 2-4 are kinetically feasible. While we favor the mechanism shown, which is by far the simplest, the evidence at this stage is not unequivocal.

Any detailed analysis of electron-transfer processes must

take into account the nature of intermediates in the reaction. Since the Cu is known to be in a hydrophobic environment, ${ }^{5,6}$ an outer sphere model is assumed for the $\mathrm{PCu}(\mathrm{II}) / \mathrm{PCu}(\mathrm{I})$ interchange. Three steps may be considered (eq 10):

$$
\begin{align*}
& \mathrm{PCu}(\mathrm{I})+\mathrm{M}(\mathrm{III}) \stackrel{K_{1}}{\rightleftharpoons} \mathrm{PCu}(\mathrm{I}), \mathrm{M}(\mathrm{III}) \\
& \stackrel{k_{\mathrm{ox}}}{\underset{k_{\text {fed }}}{\rightleftharpoons}} \mathrm{PCu}(\mathrm{II}), \mathrm{M}(\mathrm{II}) \stackrel{1 / K_{2}}{\rightleftharpoons} \mathrm{PCu}(\mathrm{II})+\mathrm{M}(\mathrm{II}) \tag{10}
\end{align*}
$$

Goldberg and Pecht ${ }^{32}$ have obtained data consistent with such a mechanism in a temperature-jump study on the reaction of azurin $\mathrm{ACu}(\mathrm{I}) / \mathrm{ACu}(\mathrm{II})$ with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-} / \mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$. In the present work we have used a sufficiently large excess of inorganic complexes, so that each reaction is driven essentially to completion. The constant $K$ is used in this paper to refer to association steps $K_{1}$ and $K_{2}$, and $k_{\text {et }}$ for $k_{\text {ox }}$ and $k_{\text {red }}$.

Two other mechanisms could account for the dependence as in eq 7. These are $\mathrm{PCu}(\mathrm{I})+\mathrm{Co}(\text { phen })_{3}{ }^{3+} \rightleftharpoons \mathrm{PCu}(\mathrm{I}), \mathrm{Co}-$ (phen) $3^{3+}$ (nonreactive), followed by $\mathrm{PCu}(\mathrm{I})+\mathrm{Co}(\text { phen })^{3+}$ $\rightarrow$ products, and, secondly, $\mathrm{PCu}(\mathrm{I}) \rightleftharpoons \mathrm{PCu}(\mathrm{I})^{*}$ to give a reactive form, followed by $\mathrm{PCu}(\mathrm{I})^{*}+\mathrm{Co}($ phen $) 3^{3+} \rightarrow$ products. We cannot rule out the first of these possibilities, although it clearly represents a more complicated situation since two binding sites are required, one of which leads to a "switching off' of redox activity. We note, however, that this is precisely what is required of $\mathrm{H}^{+}$in eq 2 . The second of the above mechanisms can be excluded since it would give identical rate constants for the $\mathrm{PCu}(\mathrm{I}) \rightarrow \mathrm{PCu}(\mathrm{I}) *$ step independent of the identity of the oxidant. This is clearly not the case since the measured quantity $k_{\text {et }}$ varies with oxidant.

A summary of overall rate constants for the oxidation of $\mathrm{PCu}(\mathrm{I})$ and $\mathrm{ACu}(\mathrm{I})$, and reductions of $\mathrm{PCu}(\mathrm{II})$ and $\mathrm{ACu}(\mathrm{II})$, is given in Table XVI. For the $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ reduction of $\mathrm{Cu}(\mathrm{II})$ close agreement of data not only with parsley, spinach, and bean plastocyanin, but with Pseudomonas aeruginosa azurin
(mol wt 13900 as compared to ca. 10500 for plastocyanin), is particularly interesting. With other redox reagents there is a wide range of $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ values which is at first difficult to explain. The parameters fall into readily defined groups depending on whether the oxidant is positive, $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}$, or negative, $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$, and likewise also for the reductants. It has been possible in two cases, the reactions with $\mathrm{Co}($ phen $) 3^{3+}$ and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$, to split $k$ into $K$ and $k_{\text {et }}$ terms, Table XVII. ${ }^{33}$ Other relevant information is included in this table. With redox partners $\mathrm{Co}(\mathrm{bpy})_{3}{ }^{3+}, \mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$, and $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{2+}$, we were unable to extend the range of complex concentrations sufficiently for diagnostic kinetic behavior consistent with association (less than first-order dependence on complex) to be observed. Upper limits for $K$ of $<50 \mathrm{M}^{-1}\left(25^{\circ} \mathrm{C}\right)$ for $\mathrm{Co}(\text { bpy })_{3}{ }^{3+},<360 \mathrm{M}^{-1}\left(25^{\circ} \mathrm{C}\right)$ for $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$, and $<450$ $\mathrm{M}^{-1}\left(7.1^{\circ} \mathrm{C}\right)$ for $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{2+}$ have been deduced from data obtained.

The results for plastocyanin and azurin, Table XVII, complement each other in a highly satisfactory manner, and certainly substantiate the complicated temperature-jump interpretation necessary in the azurin study. It is reasonable, therefore, to discuss features of the enthalpic and entropic terms corresponding to $K$ and $k_{\text {et }}$. The corresponding parameters are also available for the reaction between the two inorganic complexes, $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ and $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{3+},{ }^{34}$ and these are compared in Table XVII. We suggest that a major factor contributing to $\Delta S^{0}$ values is the charge. ${ }^{35}$ For reactants of opposite charge, charge neutralization occurs on going to the transition state, water of solvation is released, and $\Delta S^{\circ}$ is positive, whereas for reactions of like charge an increase in solvation occurs and $\Delta S^{\circ}$ is negative. On this basis the effective charge on both proteins is negative, which agrees with the results obtained from the variation of ionic strength (see below). This conclusion is opposite to that of Goldberg and Pecht ${ }^{32}$ whose reasoning is not clear to us. The numerically large values of $\Delta H^{\circ}$ obtained for the protein reactions suggest specific
complex-protein interactions, e.g., possibly H-bonding in the case of cyanide ligands, or interactions of the phenanthroline ligand with organic groups on the protein. ${ }^{36}$ An x-ray crystal structure of (poplar) $\mathrm{PCu}(\mathrm{II})$ has indicated that plastocyanin is barrel shaped with the Cu atom situated near to one end and ca. $6 \AA$ from the surface. ${ }^{5}$ A histidine group is interposed between the Cu at its closest approach to the surface, and a "stacking" type interaction between the imidazole and phenanthroline (oxidant) rings is a possibility. The buffers used might, in addition, associate with the protein. Evidence for binding of phosphate (and sulfate) to cytochrome $c$ has, for example, been reported. ${ }^{37}$ Until a wider range of ligands have been tested, a more clear-cut and satisfactory rationalization of $\Delta H^{\circ}$ values is difficult. In the case of the $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ reactions, the favorable $\Delta H^{\circ}$ outweighs the unfavorable $\Delta S^{\circ}$ due to the interaction of like charges, and results in a significant $K$ value comparable to that observed for the reactions of Co(phen) $3^{3+}$. Interestingly, the reaction of $\mathrm{PCu}(\mathrm{I})$ with cytochrome $f$, its natural redox partner, occurs with an overall positive entropy of activation, ${ }^{8}$ presumably due to the interaction of oppositely charged groups on the reactants. Also, for a number of antibody-antigen interactions it has been observed that $\Delta H^{\circ}$ and $\Delta S^{\circ}$ fall within the ranges -14 to -17 kcal $\mathrm{mol}^{-1}$ and -18 to $-25 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$, respectively. ${ }^{38}$ The large $\Delta H^{\circ}$ values have again to be satisfactorily accounted for.
Turning now to the electron-transfer step, the close agreements of $\Delta H_{\mathrm{et}}{ }^{\mp}$ and $\Delta S_{\mathrm{et}}{ }^{\ddagger}$ values firstly for reactions of $\mathrm{Cu}(\mathrm{I})$ and secondly for the $\mathrm{Cu}(\mathrm{II})$ proteins are to be noted. These values are seen to be independent of charge on the complex, which in the case of the $\mathrm{Cu}(\mathrm{I})$ reactions is $3+$ in one case and $3-$ in the other. Values of $\Delta S_{\mathrm{et}}{ }^{\ddagger}$ of around zero or, for two oppositely charged reactants, small and positive (consistent with charge neutralization) might have been expected. Taube and colleagues ${ }^{39}$ have studied intramolecular electron-transfer reaction within binuclear complexes of the type $\left[\left(\mathrm{NH}_{3}\right)_{5}-\right.$ $\left.\mathrm{Co}(\mathrm{III}) \mathrm{L} \cdots \mathrm{LRu}(\mathrm{II})\left(\mathrm{NH}_{3}\right)_{4} \mathrm{H}_{2} \mathrm{O}\right]^{5+}$, where the $\mathrm{L} \cdots \mathrm{L}$ bridging ligand is a bipyridine or bispyridyl derivative, and found $\Delta S_{\mathrm{et}}{ }^{\ddagger}$ values close to zero, consistent with such a view. Values of $\Delta S_{\mathrm{et}}{ }^{\ddagger}$ for both $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}$ and $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ oxidation of $\mathrm{Cu}(\mathrm{I})$ protein are large and negative and one possible explanation is a conformational (or coordination number) change involving the $\mathrm{Cu}(\mathrm{I})$ protein. Stellwagen and Shulman ${ }^{40}$ have previously suggested that $\Delta S_{\mathrm{et}}{ }^{\ddagger}=-31.4 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$ for the oxidation of cytochrome $c$ (II) with $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ is consistent with a conformational change. Furthermore, values of $\Delta H_{\mathrm{et}}{ }^{\ddagger}$ as high as $11.4 \mathrm{kcal} \mathrm{mol}^{-1}$ might be considered exceptional if the geometries of the $\mathrm{Cu}(\mathrm{I})$ and $\mathrm{Cu}(\mathrm{II})$ states are closely matching unless protein rearrangement is also relevant. However, the unexpectedly high barriers to electron transfer may result from the distance between the redox sites, and the absence of an efficient conducting pathway between them.
The trend of rate constants with ionic strength for the reactions of $\mathrm{PCu}(\mathrm{I})$ and $\mathrm{PCu}(\mathrm{II})$ is illustrated in Figure 7. From the slopes observed with positively and negatively charged complexes it is again concluded that the effective charge on the protein is negative. Isoelectric points for plastocyanin ( pH $4.2)^{7}$ and azurin ( pH 4.9$)^{41}$ indicate an overall negative charge on the proteins for the conditions investigated. It is not immediately clear, however, whether it is this total charge or the charge of the localized binding site which is relevant. Further investigations with stellacyanin, which has an isoelectronic point at $9.86,42$ will, it is hoped, yield further information on this question. Estimates of total protein charge from known charges on individual amino acids at pH ca. 7 give widely differing values for the plastocyanins and azurin. Since similar $\Delta H^{\circ}$ and $د S^{\circ}$ values are observed for reactions of $\mathrm{PCu}(\mathrm{II})$ and $\mathrm{ACu}(I I)$, Table XVII, it is possible that local rather than overall charge is influential in these reactions.

Overall activation parameters for the $\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{py}^{2+}+$

Figure 7. The dependence of rate constants $k$ on ionic strength ( $I$ ). Experimental points are indicated. The solid line has been obtained from eq 11 using a value $R=15 \AA$ for the total protein radius, and the broken line using a value $R_{1}=5 \AA$, corresponding to the radius of a localized site.
$\mathrm{PCu}(\mathrm{II})$ reaction, Table XVI, are consistent with trends identified in other reactions, and, although $K$ was not determined, positive $\Delta H^{\circ}$ and $\Delta S^{\circ}$ contributions in keeping with a positive-negative charge interaction seem perfectly reasonable. The kinetics for the $\mathrm{Co}($ bpy $){ }_{3}{ }^{3+}$ oxidation of $\mathrm{PCu}(\mathrm{I})$ gave no evidence for a less than first-order dependence on oxidant although a range of concentrations similar to that used for Co (phen) $3^{3+}$ was employed. Here, overall activation parameters $\left(\Delta H^{\ddagger}=9.7 \mathrm{kcal} \mathrm{mol}^{-1} ; \Delta S^{\ddagger}=-14.6 \mathrm{cal} \mathrm{K}^{-1}\right.$ $\mathrm{mol}^{-1}$ ) suggest smaller (positive) $\Delta H^{\circ}$ and $\Delta S^{\circ}$ contributions. However, the possibility of small (ca. $15 \%$ ) contributions due to the incidence of the second deprotonation $\mathrm{pH} \geqslant 7$ (which we do not fully understand) limits further discussion of these parameters.

Following Gray and coworkers, ${ }^{43}$ we have briefly tried to fit experimental data as in Figure 7 to equations of the Debye-Hückel type ${ }^{44}$ in order to try and ascertain the numerical value of the effective protein charge. The theory of the effect of ionic strength on activity coefficients derived by Bronsted and Bjerrum leads to the following equation (11) at low ionic strengths:

$$
\begin{align*}
\log k=\log k^{\prime}- & \frac{Z_{1}^{2} a \sqrt{I}}{1+b R_{1} \sqrt{I}} \\
& \quad-\frac{Z_{2}^{2} a \sqrt{I}}{1+b R_{2} \sqrt{I}}+\frac{\left(Z_{1}+Z_{2}\right)^{2} a \sqrt{I}}{1+b R_{12} \sqrt{I}} \tag{11}
\end{align*}
$$

where $k$ is the rate constant at ionic strength $I, k^{\prime}$ is the rate constant with $I \rightarrow 0, a(0.509)$ and $b$ (0.329) are constants (25 ${ }^{\circ} \mathrm{C}$ ), $Z_{1}$ and $Z_{2}$ are the charges on the reactants, $R_{1}$ and $R_{2}$ are their radii, and $R_{12}$ is the radius of the activated complex (angstroms). This equation is based on the assumption that each reagent behaves as a sphere with symmetrical distribution of charge. For the complexes used this is a reasonable assumption and the radii can be determined or estimated with reasonable accuracy. Also, $R_{12}$ can be taken as $R_{1}+R_{2}$. We have tried to use this equation to fit our data in a number of ways, (a) allowing $k^{\prime}, Z_{1}$, and $R_{1}$ to float, and fixing $Z_{2}$ and $R_{2}$ for the complex, (b) assuming $R_{1}$ for the protein is fixed at $15 \AA$, and (c) assuming the local protein charge applies over a nominal sphere of arbitrary radius $5 \AA$, and that this represents the protein reactant. No self-consistent interpretation emerged from any one of these approaches and the values of $Z_{2}$ deduced varied considerably. We doubt very much whether equations such as 11 , which have been shown to apply for inorganic complexes under the stipulated ionic strength conditions, apply to the present type of problem. The application of eq 11 is critically dependent on the range of $I(<0.01 \mathrm{M}) .{ }^{44} \mathrm{We}$
have restricted ourselves to a lower range of $I$ than that used by Gray. ${ }^{43}$

There is a further very good reason as to why it is difficult to fit the data with $\mathrm{Co}(\mathrm{phen}) 3^{3+}$ and $\mathrm{Co}(\mathrm{bpy}) 3^{3+}$ as oxidants. Close inspection of the experimental points in Figure 7 reveals that there is a slight trend showing a downward concavity in both cases. Assuming $k_{\text {et }}$ is not very much affected by $I$ it is concluded that $K$ increases appreciably with decreasing $I$ to exceed $K=2 \times 10^{3} \mathrm{M}^{-1}$ for $\mathrm{Co}(\mathrm{phen})_{3}{ }^{3+}$ at the lowest experimental $I$. Such a value would implicate considerable pro-tein-complex association even at the low reactant concentration used, so that a rate law first order in oxidant no longer applies. Values of $k$ are, therefore, suppressed at low $I$. Since $K$ will decrease with decreasing $I$ for the negatively charged reactants, no similar argument applies in the case of the $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-} / \mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ reactions.

Finally, with regard to the application of the Marcus theory, ${ }^{45}$ we feel some caution is required in view of the magnitude of $K$ values clearly applying in at least some protein-complex reactions. Three overall rate constants, $k_{12}, k_{11}$, and $k_{22}$ (where $k_{12}$ is for the cross-reaction and $k_{11}$ and $k_{22}$ are for related self-exchange processes), are generally considered in relation to this theory. Each of these values is the product of $K$ for association and $k_{\mathrm{et}}$ for electron transfer. The association parameters tend to balance out in many cases when it is legitimate to use overall rate constants. However, it only requires one of the rate constants to be influenced by a specific, i.e., nonelectrostatic interaction of magnitude now detected for the correlation to no longer apply.

Acknowledgment. It is a pleasure to acknowledge stimulating discussions with Professor P. Hemmerich and colleagues at the University of Konstanz and Professor J. Espenson. We are most grateful to Professor H. C. Freeman for information regarding the structure of (poplar) plastocyanin $\mathrm{PCu}(\mathrm{II})$ prior to publication, and to Dr. D. S. Bendall for encouragement concerning the parsley preparation. We thank Dr. R. Herbert of the Organic Chemistry Department at Leeds for the generous loan of equipment and helpful advice. M.G.S. is grateful to the Science Research Council (London) for a postdoctoral fellowship.

Supplementary Material Available: A listing of rate constants, Tables II, III, V, VIII, IX, XI, XII, XIII, and XIV (8 pages). Ordering information is given on any current masthead page.
