# Enthalpy of Formation of Dicesium Octabromodirhenium(III), $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$, and a Thermochemical Estimate of the Energy of the Re-Re Quadruple Bond 

Lester R. Morss, ${ }^{\text {*1a }}$ Robert J. Porcja, ${ }^{1 a}$ James W. Nicoletti, ${ }^{1 a}$ Joseph San Filippo, Jr.,*1a and H. Donald B. Jenkins ${ }^{1 b}$<br>Contribution from the Department of Chemistry, Rutgers, the State University, New Brunswick, New Jersey 08903, and the Department of Chemistry \& Molecular Sciences, University of Warwick, Coventry CV47 AL, United Kingdom. Received July 30, 1979

#### Abstract

The enthalpy of formation of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c})$ has been determined to be $-1171 \pm 35 \mathrm{~kJ} / \mathrm{mol}$ at 298 K by measuring its heat of oxidation by aqueous bromate. The enthalpy of formation of $\operatorname{Re}_{2} \mathrm{Br}_{8}{ }^{2-}(\mathrm{g})$ has been calculated to be $-1046 \pm 40$ $\mathrm{kJ} / \mathrm{mol}$ by calculating the lattice enthalpy of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$ in conjunction with other thermodynamic data. From estimates of enthalpies of formation of various $\mathrm{Re}-\mathrm{Br}$ species, and from estimates of the $\mathrm{Re}-\mathrm{Br}$ bond energy, the $\mathrm{Re}-\mathrm{Re}$ quadruple bond strength in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ has been estimated to be $408 \pm 50 \mathrm{~kJ} / \mathrm{mol}(98 \mathrm{kcal} / \mathrm{mol})$. This value is discussed in comparison with other recent estimates.

The explosive growth in the chemistry of compounds containing metal-metal bonds within the past 15 years has challenged many chemists to characterize these materials. Naturally, the strongest of these bonds have attracted the most interest: the multiple $\mathrm{Cr}-\mathrm{Cr}, \mathrm{W}-\mathrm{W}, \mathrm{Mo}-\mathrm{Mo}$, and Re -Re bonds are well-characterized, remarkably stable entities. Early and more recent estimates have focused on theoretical molecu-lar-orbital interpretations of the bonding and electronic spectra in these species. ${ }^{2-4}$ Observations drawn from the photochemistry of $\mathrm{Re}_{2} \mathrm{Cl}_{8}{ }^{2-}$ led to alternative estimates for the strength of this metal-metal bond. ${ }^{5}$ In one instance an effort was made to apply classical vibrational spectroscopic techniques to estimate the Re -Re quadruple bond strength. ${ }^{6}$ Most recently there have been attempts to answer this question by the application of traditional thermochemical techniques. Thus, Skinner, Cotton, and co-workers ${ }^{7}$ have reported on their attempts to assess the strength of the Mo-Mo and W-W multiple bonds found in several organometallic compounds, but
their efforts were hampered by uncertainties in ligand enthalpies of formation and metal-ligand bond strengths.

Several years ago in a report detailing the single-crystal structure determination of dicesium octabromodirhenium(III), $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$, Cotton and co-workers ${ }^{8}$ made the perspicacious observation that this particular substance might prove suitable for the necessary thermochemical measurements and latticeenergy calculations required to produce a thermochemical cycle leading to the enthalpy of the $\mathrm{Re}-\mathrm{Re}$ bond. We report here the results of our determination of this and related quantities for $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$.

Our investigation centered on three problems. The first task was to determine a calorimetric standard enthalpy of formation of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c})$, and the second was to calculate the lattice energy (or, more precisely, the lattice enthalpy $U_{\text {pot }}$ at 298 K ) of this compound. The sum of these two enthalpies would then yield $\Delta H_{f}{ }^{\circ}\left(\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}\right.$,g) (eq 1) by the thermochemical cycle ${ }^{9}$ shown in Scheme I. The third problem-and by far the least

\end{equation*}
$$

## Experimental Section

General. Potassium bromate (99.9\%), cesium bromide (99.9\%), potassium perrhenate ( $99.99 \%$ ), and potassium bromide ( $99.99 \%$ ) were purchased from several commercial sources and used without further purification. All solutions were prepared using distilled and deionized water. Unless otherwise stated all other reagents were the highest quality commercially available stock. Elemental analyses were performed by Galbraith Laboratories, Knoxville, Tenn.

Dicesium octabromodirhenium(III), $\mathrm{Cs}_{\mathbf{2}} \mathrm{Re}_{\mathbf{2}} \mathrm{Br}$, was prepared in the following manner. A solution of tetra- $n$-butylammonium octabromodirhenium $(1 \mathrm{II}),{ }^{10}\left[\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4} \mathrm{~N}\right]_{2}\left[\mathrm{Re}_{2} \mathrm{Br}_{8}\right](1.380 \mathrm{~g}, 0.922 \mathrm{mmol})$, in deoxygenated methanol ( 46 mL ) containing 16 mL of $48 \%$ aqueous hydrobromic acid was placed in a $250-\mathrm{mL}$ flask containing a Tef-lon-coated stirring bar. The flask was fitted with a condenser equipped with an addition funnel. The entire system was flushed with and subsequently maintained under an atmosphere of nitrogen. The flask was placed in a bath at $90^{\circ} \mathrm{C}$. The addition funnel was charged with a deoxygenated solution of cesium bromide ( $0.835 \mathrm{~g}, 3.92 \mathrm{mmol}$ ) in methanol-aqueous $48 \%$ hydrobromic acid ( $2.4,7.0 \mathrm{~mL}$ ). With vigorous stirring this solution was added to the flask over a period of 15 min. Heating and stirring were continued for an additional 5 min , after which time the resulting mixture was allowed to cool to ambient temperature, whereupon a deep-violet precipitate gradually formed. These crystals were collected by suction filtration on a fritted glass funnel and rinsed with anhydrous methanol until the rinsings were colorless. The dark, almost black crystals were dried in vacuo. A second crop of crystals was obtained by concentrating and cooling the mother liquor; the total yield was $91 \%$. Anal. Calcd: Cs, $20.81 ; \mathrm{Br}$, 50.03. Found: Cs, 20.87; Br, 49.49.

Examination of this material by X-ray powder diffraction techniques indicated d spacings and intensities consistent with the structure reported by Cotton et al. ${ }^{8}$

Calorimetry. A suitable oxidizing solvent was sought for determination of $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}\right)$ through an appropriate reaction scheme using the solution calorimeter described by Morss and co-workers. ${ }^{11}$ Since the isoperibol solution calorimeter is capable of measuring reaction heats in corrosive solvents that extend over periods as long as 30 min , a well-defined reaction was sought that would cleanly oxidize $\mathrm{Re}(1 \mathrm{II})$ to $\mathrm{ReO}_{4}{ }^{-}$. Unfortunately, most suitable oxidants are also likely to oxidize bromide and $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Cl}_{8}$ could not be substituted because it crystallizes as a hydrate, $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Cl}_{8} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, a substance much less tractable to lattice-energy calculations. Thus, an investigation was undertaken to determine an appropriate oxidant.

1 t is reported that slightly alkaline hypochlorite solutions will selectively oxidize bromide to hypobromite. ${ }^{12}$ The reaction rate is slow at pH 14 but increases with decreasing pH . However, at $\mathrm{pH}<10$ further reactions take place; specifically, hypochlorite begins to disproportionate and bromide is oxidized partially to bromate. Still, since preliminary measurements by ultraviolet spectrophotometry (using the $229-\mathrm{nm}$ absorption peak for $\mathrm{ReO}_{4}{ }^{-}$) showed slow but quantitative oxidation of $\mathrm{Re}(\mathrm{III})$ to $\mathrm{ReO}_{4}{ }^{-}$with this reagent, preliminary calorimeter experiments were undertaken with ampules of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c})$ and aqueous NaOCl solutions buffered by boric acid-borate between pH 10 and 8.7. At the higher pH reaction was too slow (reaction times
ca, 90 min ), while at the lower pH the heat evolved was so great that, if correct, such a value would have required the chemically unreasonable conclusion that $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$ is unstable with respect to the reaction

$$
\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c}) \rightarrow 2 \mathrm{CsBr}(\mathrm{c})+2 / 3 \mathrm{Re}_{3} \mathrm{Br}_{9}(\mathrm{c})
$$

Further confirmation that hypochlorite was not a suitable oxidant was afforded by calorimeter experiments with $\mathrm{KBr}(\mathrm{c})$ and hypochlorite buffered at pH 8.8 . The quantity of heat evolved in these experiments was much greater than could be accounted for by the sole oxidation of $\mathrm{Br}^{-}$to $\mathrm{OBr}^{-}$. We concluded that substantial oxidation of bromide to bromate was also occurring under these conditions.

Preliminary experiments suggested that $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$ reacts rapidly with excess bromate ion in acidic aqueous solution to form $\mathrm{ReO}_{4}{ }^{-}$and $\mathrm{Br}_{2}$. The possibility that bromine would be oxidized to hypobromite by excess bromate was dispelled by considering the free energy ${ }^{13}$ of reaction for the two oxidation pathways outlined below.

$$
\begin{gathered}
\mathrm{BrO}_{3}^{-}(\mathrm{aq})+5 \mathrm{Br}^{-}(\mathrm{aq})+6 \mathrm{H}^{+}(\mathrm{aq}) \rightarrow 3 \mathrm{Br}_{2}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
\Delta G^{\circ}=-181.5 \mathrm{~kJ} \\
\mathrm{BrO}_{3}^{-}(\mathrm{aq})+2 \mathrm{Br}_{2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow 5 \mathrm{HOBr}(\mathrm{aq}) \\
\Delta G^{\circ}=+52.7 \mathrm{~kJ}
\end{gathered}
$$

Obviously, only the former reaction occurs, even with bromate in excess. Thus, the overall reaction is

$$
\begin{align*}
& 16 \mathrm{H}^{+}(\mathrm{aq})+5 \mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c})+16 \mathrm{BrO}_{3}^{-}(\mathrm{aq}) \rightarrow \\
& \quad 28 \mathrm{Br}_{2}(\mathrm{aq})+10 \mathrm{ReO}_{4}^{-}(\mathrm{aq})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+10 \mathrm{Cs}^{+}(\mathrm{aq}) \tag{3}
\end{align*}
$$

A suitable reaction in hand, a calorimetric determination of its heat, $\Delta H^{\circ}(3)$, was undertaken.

Four spherical thin-walled borosilicate glass ampules were sealed with weighed quantities of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$ (c). Each was crushed and the contents allowed to react in the calorimeter ${ }^{11}$ with $870 \mathrm{~cm}^{3}$ of a solution of $0.1 \mathrm{M} \mathrm{KBrO}_{3}-0.1 \mathrm{M} \mathrm{HClO}_{4}$. The results are shown in Table I. Because of disagreement in the existing values of $\Delta H_{f}{ }^{\circ}\left(\mathrm{BrO}_{3}^{-}, \mathrm{aq}\right)$, calibration experiments were carried out under identical conditions with $\mathrm{KBr}(\mathrm{c})$ in place of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$. The results, representing the reaction

$$
\begin{align*}
5 \mathrm{KBr}(\mathrm{c})+6 \mathrm{H}^{+}(\mathrm{aq})+\mathrm{BrO}_{3}^{-}(\mathrm{aq}) \rightarrow & 5 \mathrm{~K}^{+}(\mathrm{aq}) \\
& +3 \mathrm{Br}_{2}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \tag{4}
\end{align*}
$$

are also included in Table I.

## Results and Discussion

$\Delta H_{f}{ }^{\circ}\left(\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}, \mathrm{c}\right)$. Standard-state enthalpies of formation of all species (except $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$ ) in eq 3 are given in ref 13 , so that these data could be used with the heat of reaction 3 to calculate $\Delta H_{f}{ }^{\circ}\left(\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}, \mathrm{c}\right)$. However, reaction 3 was not carried out at infinite dilution; moreover, there is evidence ${ }^{14}$ that $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{BrO}_{3}^{-}, \mathrm{aq}\right)$ is less negative than the value in these NBS tables. Therefore, the enthalpy scheme (Scheme II) was adopted to calculate $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}, \mathrm{c}\right)$.

```

The first two reactions in Scheme II represent reactions studied in this work. The average of results for reactions 3 and 4 are $\Delta H(3)=5(-1169 \pm 27) \mathrm{kJ} / \mathrm{mol}$ and $\Delta H(4)=$ $5(-18.26 \pm 0.11) \mathrm{kJ} / \mathrm{mol}$ (error limits are twice the standard deviation of the mean). To correct $\Delta H(3)$ to infinite dilution, heats of dilution of $\mathrm{HBrO}_{3}$ and $\mathrm{CsRe} \mathrm{O}_{4}$ were estimated from dilution data ${ }^{15}$ for 0.2 M solutions of $\mathrm{HNO}_{3}$ and $\mathrm{KMnO}_{4}$, respectively: $\Delta H^{\circ}(3)=5(-1169)+16(0.44)-10(-0.87)$ $=-5829 \mathrm{~kJ}$. To correct $\Delta H(4)$ to infinite dilution, heats of dilution of $\mathrm{HBrO}_{3}, \mathrm{HClO}_{4}, \mathrm{KBrO}_{3}$, and $\mathrm{KClO}_{4}$ were estimated from dilution data ${ }^{15}$ for 0.2 M solutions of $\mathrm{HNO}_{3}, \mathrm{HClO}_{4}$, $\mathrm{KNO}_{3}$, and $\mathrm{KMnO}_{4}$, respectively: $\Delta H^{\circ}(4)=5(-18.26)+$ $0.44+5 / 2(0.44)+5 / 2(0.25)-5 / 2(-0.50)-5 / 2(-0.87)=-85.7$ kJ . (Heats of dilution of $\mathrm{HBrO}_{3}$ are unimportant because they cancel between reactions 3 and 4.) Enthalpies of other reactions were taken from appropriate references. ${ }^{13,15-17 \mathrm{~b}}$. The sum of all enthalpies in the above scheme is $-(-5829)+16(-85.7)$ $+10(-379.54)+10(-10397)-90(19.87)-10(-393.8)$ $-20(-0.84)+80(-121.5)-40(-285.83)=-5855 \mathrm{~kJ}$. Thus $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}, \mathrm{c}\right)=1 / 5(-5855)=-1171 \pm 35 \mathrm{~kJ} /$ mol. Although the error limit shown is in part an estimate of uncertainties in heats of other reactions and dilutions used in this scheme, it represents principally the uncertainty in $\Delta H(3)$.

It is interesting to note that this datum may be combined with literature data ${ }^{13,15-17}$ to yield $\Delta H^{\circ}$ for the reaction

$$
\begin{equation*}
2 \mathrm{CsBr}(\mathrm{c})=2 \mathrm{ReBr}_{3}(\mathrm{c}) \rightarrow \mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c}) \tag{5}
\end{equation*}
$$

Thus, $\Delta H^{\circ}(5)=-1171-2(-405.5)-2(-167)=-26 \mathrm{~kJ}$ ( $\left.\mathrm{mol} \mathrm{Cs} 2_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}\right)^{-1}$. Roughly speaking, this enthalpy represents the difference between 1 mol of $\mathrm{Re}-\mathrm{Re}$ quadruple bonds and 2 mol of $\mathrm{Re}-\mathrm{Re}$ double bonds, ${ }^{18 a}$ since " $\mathrm{ReBr}_{3}$ " is really $1 / 3 \mathrm{Re}_{3} \mathrm{Br} 9$, and $\mathrm{Re}_{3} \mathrm{Br} r_{9}$ contains a triangular core of rhenium atoms ${ }^{18 \mathrm{~b}}$ "double bonded" ${ }^{18 \mathrm{c}}$ to each other.

Lattice Enthalpy of $\mathbf{C s}_{\mathbf{2}} \mathbf{R e}_{2} \mathbf{B r}$. The lattice energy of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$ was calculated using the method recently proposed by Jenkins and Pratt. ${ }^{19-22}$ We chose two models for the $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ ion in order to gauge the accuracy of the calculations made. The first model treated the octabromodirhenate ion as consisting of six spheres centered at the Br atom sites (so ignoring the Re atoms). From this study we obtained a value for $U_{\text {pot }}$, the total lattice enthalpy of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$, amounting to $1026 \mathrm{~kJ} \mathrm{~mol}^{-1}$. The second and probably the more acceptable model considers a ten-sphere model for the $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ ion and generated a value of $1030 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for $U_{\mathrm{pot}}\left(\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}\right)$. On the basis of these two treatments, we conclude a value for $U_{\text {pot }}$ of $1029 \pm 20 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for the salt. The corresponding charge on the Br atoms of the $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ ion was calculated as -0.30 . Since it is the nature of the lattice energy step ${ }^{19}$ to render $U_{\text {pot }}$ (the total lattice potential energy) and $\Delta H$ (the lattice enthalpy) synonymous quantities in the case of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}$, the lattice enthalpy for the process

$$
\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c}) \rightarrow 2 \mathrm{Cs}^{+}(\mathrm{g})+\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}(\mathrm{g})
$$

is assigned as $\Delta H=1029 \pm 20 \mathrm{~kJ} \mathrm{~mol}^{-1}$ on the basis of the above calculation. Equation 1 can now be solved for $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}, \mathrm{g}\right)=(-1171 \pm 35)+(1029 \pm 20)-2(76.1$ $\pm 0.2)^{24}-2(375.7)^{25}=-1046 \pm 40 \mathrm{~kJ} \mathrm{~mol}^{-1}$.

Estimates of the $\operatorname{Re}-\operatorname{Re}$ Quadruple Bond Enthalpy. To eliminate any effects of condensed species (metal-metal or halogen-halogen bonds), we considered the gas-phase reaction

$$
\begin{equation*}
2 \operatorname{Re}(\mathrm{~g})+8 \mathrm{Br}(\mathrm{~g})+2 \mathrm{e}^{-}(\mathrm{g}) \rightarrow \operatorname{Re}_{2} \mathrm{Br}_{8}{ }^{2-}(\mathrm{g}) \tag{2}
\end{equation*}
$$

for bonding comparisons with other gas-phase reactions: $\Delta H(2)=-1046-2(774.9)^{24}-8(111.88)^{13}=-3491 \mathrm{~kJ}$. (By convention, ${ }^{13}$ the enthalpy of formation of the gaseous electron is taken as zero. Since we will compare cycles with identical
numbers of electrons, this convention has no effect on absolute bond energies.)

1. Comparison of $\mathbf{M}-\mathrm{Br}$ Bond Enthalpies in $\mathrm{MBr}_{4}{ }^{-}$. The enthalpy change for the process

$$
\begin{equation*}
2 \operatorname{ReBr}_{4}^{-}(\mathrm{g}) \rightarrow \operatorname{Re}_{2} \mathrm{Br}_{8}{ }^{2-}(\mathrm{g}) \tag{6}
\end{equation*}
$$

represents the bond enthalpy of the Re-Re quadruple bond; $\Delta H(6)$ can be estimated from $\Delta H_{f}{ }^{\circ}\left(\mathrm{ReBr}_{4}{ }^{-}, \mathrm{g}\right)$ and $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}\right.$, g). Since the latter quantity is available (vide supra), $\Delta H(6)$ can be calculated if $\Delta H_{f}{ }^{\circ}\left(\mathrm{ReBr}_{4}{ }^{-}, \mathrm{g}\right)$ can be estimated.

Enthalpies of formation of tetrahedral gaseous ions $\mathrm{AlCl}_{4}^{-}$, $\mathrm{GaCl}_{4}{ }^{-}$, and $\mathrm{GaBr}_{4}{ }^{-}$have been calculated. ${ }^{26}$ For the gas-phase reactions we calculate ${ }^{13,24}$
$\mathrm{Al}(\mathrm{g})+3 \mathrm{Cl}(\mathrm{g})+\mathrm{Cl}^{-}(\mathrm{g}) \rightarrow \mathrm{AlCl}_{4}^{-}(\mathrm{g})$
$\Delta H=-1188-329-3(122)+246=-1637 \mathrm{~kJ} / \mathrm{mol}$
$\mathrm{Al}(\mathrm{g})+3 \mathrm{Br}(\mathrm{g})+\mathrm{Br}^{-}(\mathrm{g}) \rightarrow \mathrm{AlBr}_{4}{ }^{-}(\mathrm{g})$
$\Delta H=-983-329-3(112)+234=-1414 \mathrm{~kJ} / \mathrm{mol}$
$\mathrm{Ga}(\mathrm{g})+3 \mathrm{Cl}(\mathrm{g})+\mathrm{Cl}^{-}(\mathrm{g}) \rightarrow \mathrm{GaCl}_{4}^{-}(\mathrm{g})$
$\Delta H=-1029-272-3(122)+246=-1421 \mathrm{~kJ} / \mathrm{mol}$
$\mathrm{Ga}(\mathrm{g})+3 \mathrm{Br}(\mathrm{g})+\mathrm{Br}^{-}(\mathrm{g}) \rightarrow \mathrm{GaBr}_{4}{ }^{-}(\mathrm{g})$

$$
\Delta H=-828-272-3(112)+234=-1202 \mathrm{~kJ} / \mathrm{mol}
$$

We estimate the hypothetical ion $\operatorname{ReBr}_{4}{ }^{-}(\mathrm{g})$ to be slightly larger and more weakly bonded than $\mathrm{GaBr}_{4}{ }^{-}(\mathrm{g})$ and conclude that

$$
\begin{align*}
& \operatorname{Re}(\mathrm{g})+3 \mathrm{Br}(\mathrm{~g})+\mathrm{Br}^{-}(\mathrm{g}) \rightarrow \operatorname{ReBr}_{4}^{-}(\mathrm{g}) \\
& \Delta H \simeq-1180 \pm 30 \mathrm{~kJ} / \mathrm{mol} \tag{7}
\end{align*}
$$

The $\mathrm{MX}_{4}{ }^{-}$species we have cited are all tetrahedral while the rhenium centers in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ are pentacoordinate; however, we do not believe that the $\mathrm{Re}-\mathrm{Br}$ bonds are repelled more in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ than in the hypothetical $\mathrm{ReBr}_{4}{ }^{-}$ion. Using literature ${ }^{13,24}$ enthalpies of formation, $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{ReBr}_{4}{ }^{-}, \mathrm{g}\right)=\Delta H(7)$ $+\Delta H_{\mathrm{f}}{ }^{\circ}(\mathrm{Re}, \mathrm{g})+3 \Delta H_{\mathrm{f}}{ }^{\circ}(\mathrm{Br}, \mathrm{g})+\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{Br}^{-}, \mathrm{g}\right)=-1180+$ $775+3(112)-234=-303 \mathrm{~kJ} / \mathrm{mol}$. Thus, $\Delta H(6)=-1046$ $-2(-303)=-440 \mathrm{~kJ} / \mathrm{mol}$, i.e., $D_{298}(\operatorname{Re} \equiv \operatorname{Re})=400 \mathrm{~kJ}$.
2. Comparison of $\mathbf{M}-X$ Bond Enthalpies in $\mathbf{M X}_{4}(\mathrm{~g})$. The molecule $\mathrm{OsBr}_{4}$ is of interest since it is isoelectronic with the ion $\mathrm{ReBr}_{4}{ }^{-}$. We may estimate the $\mathrm{Os}-\mathrm{Br}$ bond enthalpy in $\mathrm{OsBr}_{4}(\mathrm{~g})$ by considering the gas-phase reactions

$$
\begin{align*}
& \mathrm{M}(\mathrm{~g})+4 \mathrm{Cl}(\mathrm{~g}) \rightarrow \mathrm{MCl}_{4}(\mathrm{~g})  \tag{8}\\
& \mathrm{M}(\mathrm{~g})+4 \mathrm{Br}(\mathrm{~g}) \rightarrow \mathrm{MBr}_{4}(\mathrm{~g}) \tag{9}
\end{align*}
$$

Literature data ${ }^{13,27}$ lead to $\Delta H(8)$ and $\Delta H(9)$ of -1967 and $-1700 \mathrm{~kJ} / \mathrm{mol}$ for $\mathrm{M}=\mathrm{Zr},-1262$ and -1065 for $\mathrm{Sn},-2031$ and -1804 for $T h$, and -1827 and -1574 for $U$. The average of these $\Delta H(9)$ is $236 \pm 31 \mathrm{~kJ}$ less negative than $\Delta H(8)$. Since $\Delta H(8)$ for $\mathrm{M}=\mathrm{Os}$ is $-1350 \mathrm{~kJ} / \mathrm{mol},{ }^{13}$ we estimate $\Delta H(9)$ for $\mathrm{M}=\mathrm{Os}$ to be $-1350+236=-1114 \mathrm{~kJ} / \mathrm{mol}$.

We may use the bond enthalpy in $\mathrm{OsBr}_{4}(\mathrm{~g})$ to estimate that in the isoelectronic ion $\mathrm{ReBr}_{4}{ }^{-}(\mathrm{g})$ by comparing $\Delta H(9)$ with $\Delta H$ for production of isoelectronic ions $\mathrm{M}^{\prime} \mathrm{Br}_{4}^{-}(\mathrm{g})$

$$
\begin{equation*}
\mathrm{M}^{\prime}(\mathrm{g})+3 \mathrm{Br}(\mathrm{~g})+\mathrm{Br}^{-}(\mathrm{g}) \rightarrow \mathrm{M}^{\prime} \mathrm{Br}_{4}^{-}(\mathrm{g}) \tag{10}
\end{equation*}
$$

For the isoelectronic pair $\mathrm{SiBr}_{4}(\mathrm{~g})$ and $\mathrm{AlBr}_{4}{ }^{-}(\mathrm{g}), \Delta H(9)$ and $\Delta H(10)$ are ${ }^{13,24}-1319$ and $-1414 \mathrm{~kJ} / \mathrm{mol}$, respectively. For the pair $\mathrm{GeBr}_{4}(\mathrm{~g})$ and $\mathrm{GaBr}_{4}{ }^{-}(\mathrm{g}), \Delta H(9)$ and $\Delta H(10)$ are -1125 and $-1202 \mathrm{~kJ} / \mathrm{mol}$, respectively. ${ }^{13,24}$ Since the latter pair more nearly approximate the isoelectronic pair $\mathrm{OsBr}_{4}$ and $\mathrm{ReBr}_{4}{ }^{-}$, we estimate $\Delta H(10)$ for $\mathrm{M}^{\prime}=\operatorname{Re}$ as $-1114+$ $(-1202)-(-1125)=-1191 \mathrm{~kJ} / \mathrm{mol}$, a value that represents an independent estimate of $\Delta H(7)$. This estimate leads to $\Delta H_{\mathrm{f}}{ }^{\circ}\left(\mathrm{ReBr}_{4}^{-}, \mathrm{g}\right)=-1191+775+3(112)-234=-314$
$\mathrm{kJ} / \mathrm{mol}$ and to $\Delta H(6)=-D_{298}(\mathrm{Re} \equiv \mathrm{Re})=-1046-2(-314)$ $=-418 \mathrm{~kJ} / \mathrm{mol}$.
3. Comparison of $\mathrm{Re}-\mathrm{Br}$ Bond Enthalpies in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ and $\mathrm{ReBr}_{6}{ }^{2-}$. We may consider the bonds in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ as one $\mathrm{Re} \equiv \mathrm{E}$ equadruple bond and elght $(\mathrm{Re}-\mathrm{Br})^{1 / 4-}$ bonds. From eq $2, \Delta H(2)=-D_{298}(\mathrm{Re} \equiv \mathrm{Re})-8 D_{298}(\mathrm{Re}-\mathrm{Br})^{1 / 4-}=$ -3491 kJ . To calculate $D_{298}(\mathrm{Re} \equiv \mathrm{Re})$ we need an estimate of $D_{298}(\mathrm{Re}-\mathrm{Br})^{1 / 4-}$. Although eq 7 could be rewritten to provide this estimate, it would not lead to an independent value of $D_{298}(\mathrm{Re} \equiv \mathrm{Re})$. However, we may take advantage of the enthalpy of formation and lattice enthalpy of $\mathrm{K}_{2} \mathrm{ReBr}_{6}$ recently reported by Burgess et al ${ }^{28}$ For the process

$$
\begin{equation*}
\operatorname{Re}(\mathrm{g})+6 \mathrm{Br}(\mathrm{~g})+2 \mathrm{e}^{-}(\mathrm{g}) \rightarrow \operatorname{ReBr}_{6}{ }^{2-}(\mathrm{g}) \tag{11}
\end{equation*}
$$

we calculate $\Delta H(11)=\Delta H_{\mathrm{f}}{ }^{\circ}\left(\operatorname{ReBr}_{6}{ }^{2-}, \mathrm{g}\right)-\Delta H_{\mathrm{f}}{ }^{\circ}(\mathrm{Re}, \mathrm{g})-$ $6 \Delta H_{\mathrm{f}}{ }^{\circ}(\mathrm{Br}, \mathrm{g})=-692-775-6(112)=-2139 \mathrm{~kJ}$. Since $\mathrm{ReBr}_{6}{ }^{2-}$ is octahedral, with six identical ( $\left.\mathrm{Re}-\mathrm{Br}\right)^{1 / 3-}$ bonds, $D_{298}(\mathrm{Re}-\mathrm{Br})^{1 / 3-}=2139 / 6=356 \mathrm{~kJ} / \mathrm{mol}$. To compare these $\mathrm{Re}-\mathrm{Br}$ bonds with those in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$, we must correct for the coordination number and charge on the $\mathrm{Re}-\mathrm{Br}$ bonds.

Korol'kov et al. ${ }^{29}$ have pointed out that a unit decrease in coordination number of gaseous heavy transition-metal halides is accompanied by an increase in M-X bond energy from 28 to $42 \mathrm{~kJ} / \mathrm{mol}$. Specifically, thermodynamic data ${ }^{13}$ lead to $D_{298}(\mathrm{~W}-\mathrm{Cl})=347 \mathrm{~kJ} / \mathrm{mol}$ in $\mathrm{WCl}_{6}, 377 \mathrm{~kJ} / \mathrm{mol}$ in $\mathrm{WCl}_{5}$, and $410 \mathrm{~kJ} / \mathrm{mol}$ in $\mathrm{WCl}_{4}$. We have argued above that the $\mathrm{Re}-\mathrm{Br}$ bonds in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ are repelled no more than those of a fourcoordinate $\mathrm{ReBr}_{4}$ ion; hence we correct $D_{298}(\mathrm{Re}-\mathrm{Br})^{1 / 3-}$ from coordination 6 to 4 as $356+(410-347)=419 \mathrm{~kJ} /$ mol.

We estimate the correction from $(\mathrm{Re}-\mathrm{Br})^{1 / 3-}$ to ( $\mathrm{Re}-$ $\mathrm{Br})^{1 / 4-}$ as $1 / 12 \mathrm{EA}(\mathrm{Br})=346 / 12=29 \mathrm{~kJ} ;{ }^{13}$ hence $D_{298}(\mathrm{Re}-$ $\mathrm{Br})^{1 / 4-}=419-29=390 \mathrm{~kJ} / \mathrm{mol}$. Therefore, for eq 2 , $D_{298}(\mathrm{Re} \equiv \mathrm{Re})=3491 \mathrm{~kJ} / \mathrm{mol}-8 D_{298}(\mathrm{Re}-\mathrm{Br})^{1 / 4-}=3491$ $-8(390)=371 \mathrm{~kJ} / \mathrm{mol}$.
4. Comparison with Re Metal by Bond Length Ratio. Housecroft and Wade ${ }^{30}$ recently proposed a method for estimating metal-metal and metal-ligand bonds in carbonyl clusters by comparing metal-metal bond lengths with the shortest interatomic distance in the metal itself. We apply their equation

$$
\begin{equation*}
E(\mathrm{M}-\mathrm{M})=A[d(\mathrm{M}-\mathrm{M})]^{-4.6} \tag{12}
\end{equation*}
$$

to the $\mathrm{Re}-\mathrm{Re}$ bond in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$, using its length, ${ }^{8} 2.228 \AA$, in comparison with the interatomic distance in rhenium metal, ${ }^{31}$ $2.75 \AA$. Rhenium metal is hexagonal closest packed, so that there are 6 mol of $\mathrm{Re}-\mathrm{Re}$ bonds per mol of Re metal. Thus, in Re metal $E(\operatorname{Re}-\mathrm{Re})=774.9 / 6=129.2 \mathrm{~kJ} / \mathrm{mol}$. From eq 12

$$
E\left(\operatorname{Re}-\operatorname{Re} \text { in } \operatorname{Re}_{2} \mathrm{Br}_{8}{ }^{2-}\right)=(129.2 \mathrm{~kJ} / \mathrm{mol})\left[\frac{2.228}{2.75}\right]^{-4.6}
$$

$=340 \mathrm{~kJ}$
Despite the simplicity of this argument, we believe that quantitative correlations of bond strength and bond lengths such as given in eq 12 are rather too tenuous to enable us to include this value among our estimates of the $\mathrm{Re}-\mathrm{Re}$ bond strength in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$

## Conclusions

Although estimates of the strength of quadruple bonds have ranged from 334 to more than $1500 \mathrm{~kJ} /$ mol, ${ }^{5,2 a}$ the most recent estimate for the $\mathrm{Re}-\mathrm{Re}$ quadruple bond is $480-690 \mathrm{~kJ} / \mathrm{mol}$. ${ }^{6}$ Unfortunately, this estimate suffers from the tenuous extension of the Birge-Sponer technique of classical vibrational spec-
troscopy to estimate the bond strengths of diatomic molecules. Indeed, a careful examination of the arguments leading to this estimate reveals several unsubstantiated and severe approximations, ${ }^{32}$ suggesting that any similarity between the true Re-Re bond energy and the dissociation energy reported by these workers is largely coincidental.
Recent efforts by Skinner ${ }^{7}$ and others to study the thermochemistry of organometallic compounds have included estimates of metal-metal bond strengths. In particular, solution calorimetry studies ${ }^{33}$ of molybdenum(II) acetate, $\mathrm{Mo}_{2}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{4}$, yielded a standard enthalpy of formation for this compound from which a value of $D_{298}(\mathrm{Mo} \equiv \mathrm{Mo})$ was "assessed in the region of $500 \mathrm{~kJ} / \mathrm{mol}$ ", a value which Skinner ${ }^{7}$ concludes to be a "provisional . . . upper limit".
We have determined the enthalpy of formation of $\mathrm{Cs}_{2} \mathrm{Re}_{2} \mathrm{Br}_{8}(\mathrm{c})$, calculated the lattice enthalpy of this compound, and derived the enthalpy of formation of $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}(\mathrm{g})$. From this datum and reasonable bond-enthalpy arguments, we obtain estimates for the $\operatorname{Re}-\operatorname{Re}$ bond of 440,418 , and 371 $\mathrm{kJ} / \mathrm{mol}$. In summary, we believe that the best thermochemical estimate of the rhenium-rhenium quadruple bond in $\mathrm{Re}_{2} \mathrm{Br}_{8}{ }^{2-}$ is $408 \pm 50 \mathrm{~kJ} / \mathrm{mol}(98 \mathrm{kcal} / \mathrm{mol})$.

# Reduction of Coordinated Carbon Monoxide. Synthesis of Neutral Metal Formyl and Hydroxymethyl Derivatives of the $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})_{2}(\mathrm{NO})^{+}$Cation 

Charles P. Casey,* Mark A. Andrews, Donald R. McAlister, and James E. Rinz<br>Contribution from the Department of Chemistry, University of Wisconsin, Madison, Wisconsin 53706. Received August 6, 1979

#### Abstract

The reaction of $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})_{2}(\mathrm{NO})^{+} \mathrm{PF}_{6}-$ (1) with potassium triisopropoxyborohydride in tetrahydrofuran at $-78^{\circ} \mathrm{C}$ gives the neutral formyl complex $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})(\mathrm{NO})(\mathrm{CHO})(2)$ as an orange oil. Dilute solutions of $\mathbf{2}$ gradually decompose at room temperature to give $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})(\mathrm{NO})(\mathrm{H})(4)$. Reduction of 2 with $\mathrm{BH}_{3}$.THF yields $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})$ ( NO ) $\left(\mathrm{CH}_{3}\right)(5)$, while reduction of 2 with lithium triethylborohydride gives the diformyl complex $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{NO})(\mathrm{CHO})_{2}{ }^{-}$ (7). Formyl complex 2 is unstable in neat oil form and disproportionates to give the dimeric metallo ester $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)(\mathrm{CO})(\mathrm{NO})$ $\mathrm{ReCO}_{2} \mathrm{CH}_{2} \mathrm{Re}(\mathrm{CO})(\mathrm{NO})\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)(8)$ as a $\sim 1: 1$ mixture of two diastereomers. Prolonged solvolysis of 8 in methanol yields the methyl ester $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})(\mathrm{NO})\left(\mathrm{CO}_{2} \mathrm{CH}_{3}\right)$ (6) and the methoxymethyl complex $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})(\mathrm{NO})\left(\mathrm{CH}_{2} \mathrm{OCH}_{3}\right)(9)$. Ether 9 can be hydrolyzed with water-tetrahydrofuran under acid catalysis to give the first unsubstituted hydroxymethyl complex, $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})(\mathrm{NO})\left(\mathrm{CH}_{2} \mathrm{OH}\right)(3)$. Previous claims of the isolation of 3 are shown to be inaccurate. Complex 3 may also be more readily obtained by treatment of cation 1 with sodium diethylaluminum dihydride.

## Introduction

The shortage of petroleum has caused increased interest in alternative sources of liquid fuels and petrochemical feedstocks. One such alternative that is now being widely investigated is the reduction of coal-derived carbon monoxide-hydrogen mixtures via the Fischer-Tropsch and related reactions. ${ }^{1}$ For the past several years, we have been studying some of the unusual intermediates and reactions which have been proposed to occur in CO reduction. Many of our studies have centered around metal formyl species ${ }^{2}$ which may be involved in the initiation step of CO reduction. The first formyl complex, $(\mathrm{CO})_{4} \mathrm{FeCHO}^{-}$, was synthesized by Collman from $\mathrm{Fe}(\mathrm{CO})_{4}{ }^{2-}$ and acetic-formic anhydride. ${ }^{3}$ Unfortunately, this route did not prove to be general and $\mathrm{we}^{2}$ and others ${ }^{4}$ have developed syntheses of a variety of anionic metal formyl complexes by treatment of neutral metal carbonyl compounds with borohydrides such as potassium triisopropoxyborohydride. The low formyl CO stretching frequencies observed for these anionic species (for example, $1600 \mathrm{~cm}^{-1}$ for ( CO$)_{4} \mathrm{FeCHO}^{-}$) indicated a large contribution from carbenoid resonance structures such as II which place extensive negative charge on the formyl oxygen atom. The possibility that anionic metal formyl compounds might be anomalously stabilized by such resonance structures led us to investigate syntheses of neutral

metal formyl complexes by hydride reduction of cationic metal carbonyl compounds.

At the time we began this work, only one neutral metal formyl species had been reported, the unstable and only partially characterized $\mathrm{Os}(\mathrm{CO})_{2}\left[\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right]_{2} \mathrm{Cl}(\mathrm{CHO})$. $^{5.14}$ Neutral metal formyl species had been suggested as intermediates in the substitution reactions of metal carbonyl hydride complexes, ${ }^{62}$ in the reaction of methoxide with $\mathrm{Ru}\left[\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right]_{3} \mathrm{ClH}$ toeventually give $\mathrm{Ru}\left[\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right]_{3}(\mathrm{CO})$ $\mathrm{H},{ }^{6 \mathrm{~b}}$ and in the sodium borohydride reductions of the metal carbonyl cations $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{W}(\mathrm{CO})_{3}\left[\mathrm{P}_{\left.\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right]^{+7} \text { and }}\right.$ $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})_{2} \mathrm{NO}^{+8}$ to methyl and hydroxymethyl metal complexes.

In a preliminary communication, we reported that the reaction of $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \operatorname{Re}(\mathrm{CO})_{2} \mathrm{NO}^{+} \mathrm{PF}_{6}{ }^{-}$(1) with $\mathrm{K}^{+} \mathrm{HB}\left[\mathrm{OCH}\left(\mathrm{CH}_{3}\right)_{2}\right]_{3}{ }^{-}$gave the neutral metal formyl complex $2 .{ }^{9}$ In addition, we found that the claimed synthesis ${ }^{10}$ of the only reported hydroxymethyl complex, $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Re}(\mathrm{CO})$ ( NO ) $\left(\mathrm{CH}_{2} \mathrm{OH}\right)(3)$, was inaccurate and eventually succeeded in preparing authentic 3 by two alternate routes. ${ }^{11}$ Here we
