generated by the present method, since their precursors are readily accessible from $o$-tolualdehyde. ${ }^{5}$

In a parallel line of experiments, cyclopentanone moiety $\mathbf{1 3}$ was prepared in an almost stereoisomerically pure form, starting from 2 -methyl- 2 -cyclopentenone (12) by modification ${ }^{8}$ of the reported method. ${ }^{\text {c. } \mathrm{d}, \mathrm{f}}$
The assembly of the bromide 13 with $\mathbf{3}$ was carried out by adding 13 to the benzylic carbanion 5 at $-75^{\circ} \mathrm{C}$ to room temperature, which had been generated in situ from 3, according to the procedure described above. In the assembly of the bromide 13 with 4, HMPA was added to the carbanion 6 , generated in situ prior to the alkylation. Deketalization of the coupling products 7 and 8 afforded the crucial precursors 14 and $\mathbf{1 5}^{10}$ as stereoisomeric mixtures [14, 2:1;11 $15,1: 2$ (the former is less polar)] in $94 \%$ and $95 \%$ yields, respectively, after preparative TLC [14: TLC on silica gel, $R_{f} 0.60\left(6: 4 \mathrm{AcOEt}-\mathrm{C}_{6} \mathrm{H}_{6}\right) ; 15$ : TLC on silica gel, $R_{f} 0.59$ and 0.38 ( $6: 4 \mathrm{AcOEt}-\mathrm{C}_{6} \mathrm{H}_{6}$ )].

The final intramolecular cyclization of 14 and 15 via the corresponding $o$-quinodimethanes was exemplified with the estrone synthesis. To an acetonitrile solution ( 20 mL ) of a diastereo-

(11) The ratio of the stereoisomers was determined by NMR spectrum.

CsF ( 2.2 mmol ) in 10 mL of acetonitrile at once at reflux; the mixture was heated for 1.5 h . The reaction mixture was evaporated in vacuo, triturated with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and filtered to remove the insoluble materials. The filtrate was evaporated and chromatographed on silica gel with chloroform solvent (TLC, $R_{f} 0.45$ ) to afford estrone methyl ether (18) ${ }^{12}$ in $86 \%$ yield based on 14 , which was identified by comparison of its spectral data with those of the authentic sample. The similar treatment of $\mathbf{1 5}$ gave rise to $6 \beta$-methylestra-1,3,5(10)-trien-17-one (2) ${ }^{14}$ in $95 \%$ yield. It was identified by comparison of the spectral data with those of the authentic sample, which was independently prepared via hydrogenation on Pd/C of 6-methylestra-1,3,5(10),6-tetraen-17-ol, starting with estradiol 17 -monoacetate. ${ }^{15,16}$

The simplicity and versatility of the present methodology for the generation of $o$-quinodimethane intermediate have been demonstrated by the stereoselective syntheses of estrone and $6 \beta$-methylestra-1,3,5(10)-trien-17-one. Furthermore, the generation of $o$-quinodimethanes with appropriate substituents on the aromatic nucleus and the $\alpha$ and $\alpha^{\prime}$ carbons is expected in our methodology, which makes derivatization of steroidal skeleton possible. ${ }^{17}$ Further extensions of the methodology are now in progress in our laboratory.

Acknowledgment. We are grateful to Shin-etsu Chemical Industry Co., Ltd., for the generous gift of trimethylchlorosilane. We also thank Teikoku Horm. Manufacturing Company for providing estradiol 17 -monoacetate, which was used to prepare the authentic sample of $6 \beta$-methylestra-1,3,5(10)-trien-17-one.
(12) Estrone methyl ether thus obtained contained ca. $7-8 \%$ of $\mathrm{C}(9)$ epimer, but recrystallization from AcOEt afforded pure estrone methyl ether, mp 183.5-185 ${ }^{\circ} \mathrm{C}$ (lit. $.^{13} 183.2-184^{\circ} \mathrm{C}$ ).

Our earlier studies ${ }^{1}$ of nonbonded atomic contacts with divalent sulfur in crystals revealed that electrophiles tend to approach sulfur roughly $20^{\circ}$ from the perpendicular to the plane through atoms $\mathrm{Y}-\mathrm{S}-\mathrm{Z}$, whereas nucleophiles tend to approach approximately along the extension of one of the covalent bonds to S , indicating

[^0]

Figure 1. The approach of $\mathrm{S}_{j}$ relative to the plane of $\mathrm{Y}_{i}-\mathrm{S}_{i}-Z_{i}$ and $\mathrm{S}_{i}$ relative to that of $\mathrm{Y}_{j}-\mathrm{S}_{j}-\mathrm{Z}_{j}$. The polar angles $\theta_{i}, \theta_{j}$ measured so that $0^{\circ}$ $\leq \theta \leq 90^{\circ}$ and azimuthal angles $\left.\phi_{i}, \phi_{j}\left(0 \leq \phi \leq 80^{\circ}\right) 180^{\circ}\right)$ are spherical polar coordinates specifying the direction of the vector $S_{i} \cdots S_{j}$ with respect to the planes $Y_{i}-S_{i}-Z_{i}$ and $Y_{j}-S_{j}-Z_{j}$. Vectors $n_{i}, n_{j}$ are normal to the sulfide planes, $\mathbf{b}_{i}, \mathbf{b}_{j}$ bisect angles $\alpha_{i}\left(Y_{i}-\mathrm{S}_{i}-\mathrm{Z}_{i}\right)$ and $\alpha_{j}\left(\mathrm{Y}_{j}-\mathrm{S}_{j}-\mathrm{Z}_{j}\right)$, and $\mathbf{p}_{i}$, $\mathbf{p}_{j}$ show the direction of $\mathrm{S}_{i} \cdots \mathrm{~S}_{j}$ projected onto the sulfide planes.
data base and related programs for automatic retrieval of such contacts. ${ }^{3}$ Of the 18648 structures in the data base (up to 1978), 2784 contained divalent sulfur (bonded to two ligands, neither one being H), and 57 of these structures contained 151 nonbonded $\mathrm{S} \cdots \mathrm{S}$ intermolecular contacts. Each $\mathrm{S}_{i} \cdots \mathrm{~S}_{j}$ contact is associated with two sets of angles $\left(\theta_{i}, \phi_{i}\right)$ and $\left(\theta_{j}, \phi_{j}\right)$, corresponding to the approach $S_{j}$ relative to the plane of $Y_{i}-S_{i}-Z_{i}$ and $S_{i}$ relative to that of $Y_{j}-S_{j}-Z_{j}$, respectively (Figure 1). The two sets of values of $\theta, \phi$ for each contact were calculated automatically by using a computer program. Of the two values of $\theta$ for each contact, the lower one is denoted as $\theta_{i}$ and the other as $\theta_{j} ; \theta_{i}$ and $\theta_{j}$ are plotted in Figures 2 and 3. As Figures 2 and 3 imply, a majority of $\theta_{i}$ and $\theta_{j}$ values (filled and open circles, respectively) fall into two classes, corresponding to type I for $\theta_{i}$ 's (electrophile) and type II for $\theta_{j}$ 's (nucleophile). The ratio of the expected to observed number of contacts ${ }^{4}$ for a given range in $\theta$ was calculated (Figure 2). It shows that there is a preference for $\theta$ to be $<30^{\circ}$ (type I) or $\theta>75^{\circ}$ (type II). Figure 3 shows that type II contacts tend to lie along the extension of a sulfur bond. Figure 4, which illustrates the correlation of $\theta_{i}$ vs. $\theta_{j}$ for each of the contacts, shows

Figure 2. Polar graphs of $d\left(\mathrm{~S}_{i} \cdots \mathrm{~S}_{j}\right)$ vs $\theta$. Of the two values of $\theta$ for each $\mathrm{S}_{i} \cdots \mathrm{~S}_{j}$ contact, the lower one is denoted as $\theta_{i}$ (filled circles) and the higher one as $\theta_{j}$ (open circles). Triangles define type III contacts ( $\theta_{i}=\theta_{j}$ ); open triangles have $\phi_{i} \approx \phi_{j}$ (within $5^{\circ}$ ) and closed triangles have $\phi_{i} \neq \phi_{j}$. The number of observed and expected contacts in each angular range of $15^{\circ}$ and the normalized value of their ratio are given on the inner edge of the arcs. Deviation from unity for the ratio represents deviation from random distribution. Overlapping symbols are slightly displaced for clarity. The mean values of the S...S distances for type III $(\Delta, \Delta)$ and type I-II $(\mathbf{O}, \bullet)$ contacts are shown along the outer edge of the arcs. These values are calculated for $30^{\circ}$ ranges in $\theta$ and are marked at the middle of each range.
the preferred directions of electrophilic and nucleophilic attack on divalent sulfur. We have now extended these studies to include S...S interactions in crystals, which show that a majority of these interactions may also be regarded as the incipient formation of an attractive electrophile-nucleophile pairing. If one sulfur $\left(S_{1}\right)$ in this pair approaches the sulfide plane of the other sulfur $\left(\mathrm{S}_{2}\right)$ along specific directions corresponding to an electrophile, the direction of approach of $S_{2}$ relative to the sulfide plane of $S_{1}$ is also specific and complementary and corresponds to a nucleophile.

A sulfur atom $S_{i}$, not covalently bonded to a particular $S_{j}$, was considered to make a "nonbonded contact" if the $S_{i} \cdots \cdot S_{j}$ distance was not greater than $3.7 \AA$, which is twice the traditional ${ }^{2}$ van der Waals radius of sulfur. We searched for such nonbonded contacts in crystal structures, using the Cambridge crystallographic
a preference for values around $\theta_{i} \approx 30^{\circ}$ and $\theta_{j} \approx 75^{\circ}$ for type I-II contacts. Thus, the two sets of $\theta, \phi$ values for each contact reveal a complementarity: if one sulfur, $\mathrm{S}_{\mathrm{j}}$, is regarded as an

(4) Assuming that the vectors $S_{i} \cdot . S_{j}$ have a purely random relation to each other, the number of contacts occurring in the angular range $\theta$ and $\theta+\mathrm{d} \theta$ is proportional to $\sin \theta \mathrm{d} \theta$. The ratio of the observed to expected number of contacts for each angular range of $15^{\circ}$ was calculated by counting the observed contacts in each grid (Figure 2) and normalizing this count to the number of the expected contacts in each range.

Figure 3. Polar graph of $\theta$ vs. $|\phi|$, the absolute value of $\phi$, indicates spatial distribution of $S_{i} \cdots S_{j}$ contacts. No distinction is made here between contacts above or below the sulfide planes or between $S-Y$ and $S-Z$. Shaded areas represent the sulfide plane in Figure 2 and the $S-Y$ and $S-Z$ bonds in Figure 3.

Figure 4. Shows correlation of $\theta_{i}$ vs. $\theta_{\mathrm{j}}$ for each of the contacts. The squares show type I-II contacts.
electrophile (filled circles) in terms of its $\theta_{i}, \phi_{i}$ values which define its approach to the plane $\mathrm{Y}_{i}-\mathrm{S}_{i}-\mathrm{Z}_{i}$, the $\theta_{j}, \phi_{j}$ values for the approach of the other sulfur, $\mathrm{S}_{i}$, to the $\mathrm{Y}_{j}-\mathrm{S}_{j}-\mathrm{Z}_{j}$ plane correspond to a nucleophile (open circles).

Some contacts (36), denoted by triangles, do not follow the above pattern and form a third group (type III) by themselves; for most of these contacts, $\theta_{i}=\theta_{j}$ due to a crystallographic center of symmetry. For the others, $\theta_{i} \sim \theta_{j}$ even without any such crystallographic symmetry requirement. These contacts are further subdivided into two classes, those with $\phi_{i} \sim \phi_{j}$ (within $5^{\circ}$ ) (open triangles, type IIIa) and those with $\phi_{i} \neq \phi_{i}$ (filled triangles, type IIIb). All type III contacts, in general, are shorter than type I and type II contacts, ${ }^{5}$ especially for $\theta>45^{\circ}$, indicating nonspherical effective shapes ${ }^{6-8}$ for sulfur (see Figure 3). Type IIIa contacts may be interpreted as a nucleophilic attack of one sulfur on another; since both the sulfurs approach each other in
plane, there is no electrophile-nucleophile pairing.
The "frontier-orbital" model ${ }^{1,9}$ provides a convenient frame for discussing the directional preferences of the nonbonded atomic contacts with divalent sulfur. The majority of the $\mathrm{S} . . \mathrm{S}$ contacts correspond to electrophile-nucleophile (type I-type II) pairing; their mutual approach directions indicate ${ }^{1}$ interaction of the highest occupied molecular orbital (HOMO), which is essentially a sulfur lone-pair orbital extending nearly perpendicular to the Y-S-Z plane, with the lowest unoccupied molecular orbital (LUMO), which is a $\sigma^{*}(\mathrm{~S}-\mathrm{Y})$ or $\sigma^{*}(\mathrm{~S}-\mathrm{Z})$ orbital. For type IIIa contacts, there is no such electrophile-nucleophile pairing and no HOMO-LUMO interaction; one sulfur approaches the other along the $\sigma^{*}(\mathrm{~S}-\mathrm{Y})$ or $\sigma^{*}(\mathrm{~S}-\mathrm{Z})$ of the other (see, however, ref 7).

These results indicate that there are preferred and complementary directions of electrophilic and nucleophilic attack on one divalent sulfur by another divalent sulfur in the incipient stages of chemical reactions, and these regularities display features of orbital distribution around sulfur. It is quite remarkable that these regularities due to orbital interactions are evident in the environment around sulfur in crystals and are the basis of some of the strongest intermolecular forces in these crystals.

Acknowledgment. We thank the National Institutes of Health (Grant CA 23704) for financial support.
(5) Type III contacts clearly show an anisotropic shape for sulfur atoms in crystals. The difference of the means of type III contacts at $\theta=15$ and $\theta=75^{\circ}$ was tested for significance using Student's $t$ distribution. The mean contact distances at $\theta=15$ and $75^{\circ}$ are different at the 0.005 significance level. Similarly, the mean S.․ S contact distances for type III and type I-II contacts at $\theta=75^{\circ}$ but not at $\theta=15^{\circ}$ are significantly different at a level of 0.005 .
