$\mathrm{Hz}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $(20.0 \mathrm{MHz})\left(\mathrm{Me}_{4} \mathrm{Si}\right) \mathrm{Me}_{2} \mathrm{~N}\left(\mathrm{~d}, \delta 43.04, J_{\mathrm{PNC}}\right.$ $=12.9 \mathrm{~Hz}$ ), $\mathrm{C}_{5} \mathrm{Me}_{5}(\mathrm{~s}, \delta 10.76), C_{5} \mathrm{Me}_{5}\left(\mathrm{~d}, \delta 130.4, J_{\mathrm{PC}}=11.8\right.$ Hz ). Several pieces of spectroscopic evidence lead to the conclusion the $\mathrm{Me}_{5} \mathrm{C}_{5}$ ring of 3 is not bonded in the monohapto manner: (i) The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of 3 indicate that the ring and Me carbons of the $\mathrm{Me}_{5} \mathrm{C}_{5}$ moiety are equivalent; moreover, the equivalence of the methyl groups persists to -100 and $-80^{\circ} \mathrm{C}$ in ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR experiments, respectively. (ii) The ${ }^{31} \mathrm{P}$ chemical shift of $3(111.0 \mathrm{ppm}){ }^{5}$ is 33.8 ppm upfield (i.e., shielded) compared to that of the phosphorus(III) chloride precursor, 1. In all cases reported thus far, phosphenium ion formation via halide ion abstraction from precursor phosphorus(III) halides has been accompanied by a downfield ${ }^{31}$ P NMR chemical shift of $>100 \mathrm{ppm}{ }^{7}$ We attribute the upfield shift to multihapto bonding between $\mathrm{P}^{+}$and the $\mathrm{Me}_{5} \mathrm{C}_{5}$ ligand and concomitant delocalization of the positive charge in the resulting cluster. Support for this suggestion is provided by the fact that $\sim 100 \mathrm{ppm}$ upfield ${ }^{11}$ B NMR chemical shifts have been observed ${ }^{8}$ when pentahapto boron cations, $\left.\left[\eta^{5}-\mathrm{Me}_{5} \mathrm{C}_{5}\right) \mathrm{BX}\right]^{+}$, are formed via $\mathrm{X}^{-}$abstraction from the corresponding monohapto boron dihalides, ( $\eta^{1}$ $\left.\mathrm{Me}_{5} \mathrm{C}_{5}\right) \mathrm{BX}_{2}$.

Treatment of 2 with $\mathrm{Al}_{2} \mathrm{Cl}_{6}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution results in the arsenium salt $\left[\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right)\left(\mathrm{Me}_{2} \mathrm{~N}\right) \mathrm{As}\right]^{+}\left[\mathrm{AlCl}_{4}\right]^{-}(4) .{ }^{9}{ }^{1} \mathrm{H}$ NMR ( 200 $\mathrm{MHz}) \mathrm{Me}_{2} \mathrm{~N}(\mathrm{~s}, \delta 3.32) \mathrm{Me}_{5} \mathrm{C}_{5}(\mathrm{~s}, \delta 2.17) ;{ }^{13} \mathrm{C}\left\{{ }^{\mathrm{l}} \mathrm{H}\right\} \mathrm{NMR}(20.0$ $\mathrm{MHz})\left(\mathrm{Me}_{4} \mathrm{Si}\right) \mathrm{Me}_{2} \mathrm{~N}(\mathrm{~s}, \delta 38.14), \mathrm{Me}_{5} \mathrm{C}_{5}(\mathrm{~s}, \delta 10.98), \mathrm{Me}_{5} \mathrm{C}_{5}$ ( $\mathrm{s}, \delta 126.88$ ); ${ }^{27} \mathrm{Al}$ NMR ( $\mathrm{s}, 103.5 \mathrm{ppm}, w_{\mathrm{h}} \sim 14 \mathrm{~Hz}$ ). The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ chemical shift equivalence of the $\mathrm{Me}_{5} \mathrm{C}_{5}$ ring persisted to $-80^{\circ} \mathrm{C}$.

The foregoing NMR observations on cations 3 and 4 are consistent with a static pentahapto structure (5) or with tri- and dihapto structures with low barriers to migration such as 6 and 7, respectively. Structure 6 is analogous to phosphonium or

5

6

7
arsonium ions, while 7 is, in essence, a phosphiran or arsiran stabilized by allyl cation attachment. ${ }^{10}$ MNDO calculations ${ }^{11}$ on $\left[\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right)\left(\mathrm{Me}_{2} \mathrm{~N}\right) \mathrm{P}\right]^{+}$reveal the following: (i) the global minimum is 7 , (ii) 5 and 6 do not correspond to minima, ${ }^{12}$ and (iii) the barrier to circumannular migration of the $\mathrm{Me}_{2} \mathrm{NP}$ moiety in 7 via an $\eta^{1}$ intermediate is very low ( $<2 \mathrm{kcal} / \mathrm{mol}$ ). ${ }^{13}$

The reaction of $\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right) \mathrm{PCl}_{2}$ with $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{Li}$ results in many products; however, the reaction of $\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right) \mathrm{AsCl}_{2}$ with $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{Li}$ proceeds cleanly and results in $\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right)\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{AsCl}(8) .{ }^{1} \mathrm{H}$ NMR

[^0] ferences for 5 and 7 and the analogous unpermethylated structures.
( 60 MHz ) $\mathrm{Me}_{5} \mathrm{C}_{5}\left(\mathrm{~s}, 15 \mathrm{H}, \delta 1.73\right.$ ), $\mathrm{C}_{5} \mathrm{H}_{5}\left(\mathrm{~s}, 5 \mathrm{H}, \delta 5.74\right.$ ); ${ }^{13} \mathrm{C}$ $\left\{{ }^{[ } \mathrm{H}\right\}$ NMR $(20.0 \mathrm{MHz})\left(\mathrm{Me}_{4} \mathrm{Si}\right) \mathrm{Me}_{5} \mathrm{C}_{5}(\mathrm{~s}, \delta 132.6), \mathrm{Me}_{5} \mathrm{C}_{5}$ (s, $\delta 12.37$ ), $\mathrm{C}_{5} \mathrm{H}_{5}$ (br, $\delta 124.03$ ). Treatment of 8 with a stoichiometric quantity of $\mathrm{Al}_{2} \mathrm{Cl}_{6}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ results in the arsenium salt $\left[\left(\mathrm{Me}_{5} \mathrm{C}_{5}\right)\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{As}\right]^{+}\left[\mathrm{AlCl}_{4}\right]^{-}(9) .{ }^{9}{ }^{1} \mathrm{H}$ NMR ( 200 MHz ) $\mathrm{Me}_{5} \mathrm{C}_{5}$ (s, $15 \mathrm{H}, \delta 2.17$ ), $\mathrm{C}_{5} \mathrm{H}_{5}(\mathrm{~s}, 5 \mathrm{H}, \delta 6.72) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( 20.0 MHz ) $\left(\mathrm{Me}_{4} \mathrm{Si}\right) \mathrm{Me}_{5} \mathrm{C}_{5}(\mathrm{~s}, \delta 130.9), \mathrm{Me}_{5} \mathrm{C}_{5}(\mathrm{~s}, \delta 10.46), \mathrm{C}_{5} \mathrm{H}_{5}(\mathrm{~s}$, $\delta 119.8$ ); ${ }^{27} \mathrm{Al}$ NMR (s, $\delta 103.5, w_{\mathrm{h}} \sim 14 \mathrm{~Hz}$ ). The chemical shift equivalence in both cyclopentadienyl rings persists to $-80^{\circ} \mathrm{C}$, and MNDO calculations on the model compound ( $\left.\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{P}^{+}$indicate that the bis(pentahapto) structure represents a global minimum which is $16 \mathrm{kcal} / \mathrm{mol}$ more stable than the bis(monohapto) structure. We therefore suggest the following structure for 9 .

## Isomerization of Silene to Ketene in the Photolysis of Pentamethyldisilanyldiazoacetate

## Wataru Ando,* Akira Sekiguchi, and Takashi Sato

Department of Chemistry, The University of Tsukuba
Niiharigun, Ibaraki 305, Japan
Received April 2, 1981
We have recently presented evidence for the formation of a silene intermediate in the decomposition of ethyl (trimethylsilyl)diazoacetate. ${ }^{1}$ The major question remaining is the source of alkoxysilylketene $\mathbf{2}$ in the gas-phase decomposition of the silyldiazoacetate. ${ }^{2,3}$ The Wolff rearrangement may have a radical

or even ionic component. As an alkoxy group migrates to an adjacent position on its way to ketene 3 , it finds itself in the neighborhood of a silicon atom and adds with or without simultaneous migration of a methyl group to give the ketene 2.

[^1]Another possibility may involve the isomerization of silene 1 to the rearranged ketene 2. Despite the amount of work done in this area, the mechanistic question for ketene 2 remains unresolved. We wish to present here definitive evidence for the isomerization of silene 1 to ketene 2.

One might expect that the trimethylsilyl group in the diazo compound $4^{4}$ should have a considerably better migrating tendency than the methyl group. Photolysis of ethyl pentamethyldisilanyldiazoacetate (4) $(0.89 \mathrm{mmol})$ for 2 h with a high-pressure mercury lamp in THF cleanly produced (ethoxydimethylsilyl)(trimethylsilyl)ketene (5) in quantitative yield. The spectral data of 5 serve to establish the structure: $\mathrm{NMR}\left(\mathrm{CCl}_{4}, \delta\right) 0.22$ ( $\mathrm{s}, 9$ $\mathrm{H}, \mathrm{SiMe}_{3}$ ), 0.26 (s, $6 \mathrm{H}, \mathrm{SiMe}_{2}$ ), 1.17 ( $\mathrm{t}, 3 \mathrm{H}, \mathrm{OCCH}_{3}$ ), and 3.68 ( $\mathrm{q}, 2 \mathrm{H}, \mathrm{OCH}_{2}$ ); IR $(\mathrm{NaCl}) 2080(\mathrm{C}=\mathrm{C}=\mathrm{O})$ and $1080 \mathrm{~cm}^{-1}$ ( $\mathrm{Si}-\mathrm{O}-\mathrm{C}$ ); mass spectrum, $m / e 216\left(\mathrm{M}^{+}\right)$. The structure of

5 was further supported by reactions with alcohols. An interesting product, (methoxydimethylsilyl)(trimethylsilyl)ketene (6), ${ }^{5}$ was obtained when treated with methanol. Methoxysilane $7^{6}$ could be isolated on heating with methanol. Similarly, the reaction of 5 with ethanol gave the ethoxysilane $8 .{ }^{7}$

Support for the intervention of the silene intermediate in the reaction of 4 was substantiated by photolysis in alcohols. Silene 9 was trapped as an alkoxysilane 10 in high yield. ${ }^{8}$ Surprisingly, $\mathrm{O}-\mathrm{H}$ insertion and Wolff rearrangement products were not observed by GLC analysis, whereas these were major reactions in ethyl (trimethylsilyl)diazoacetate. ${ }^{1-3}$ Low-temperature photolysis of 4 in the rigid matrix of methanol/tetrahydro-2-methylfuran at $-196^{\circ} \mathrm{C}$ suppressed the isomerization of silene 9 to ketene 5 to some extent.

Similar results were obtained with tert-butyl alcohol, but the results suggest that the relative difficulty in the reaction of the silene with a steric hindered alcohol is reflected in increasing amounts of ketene $5 .{ }^{9}$
(4) Compound 4 was prepared by the reaction of bis(pentamethyldisilanyl) sulfide with diethyl mercuribis(diazoacetate) in $38 \%$ yield. NMR ( $\mathrm{CCl}_{4}, \delta$ ) $0.12\left(\mathrm{~s}, 9 \mathrm{H}, \mathrm{SiMe}_{3}\right), 0.25\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{SiMe}_{2}\right), 1.27\left(\mathrm{t}, 3 \mathrm{H}, \mathrm{OCCH}_{3}\right)$, and 4.13 $\left(\mathrm{q}, 2 \mathrm{H}, \mathrm{OCH}_{2}\right)$; IR $(\mathrm{NaCl}) 2100\left(\mathrm{~N}_{2}\right)$ and $1690 \mathrm{~cm}^{-1}\left(\mathrm{CO}_{2}\right) ;$ UV $\lambda_{\max }$ ( MeOH ) $381 \mathrm{~nm}(\epsilon 125$ ).
(5) Compound 6: NMR ( $\left.\mathrm{CCl}_{4}, \delta\right) 0.20$ (s, $9 \mathrm{H}, \mathrm{SiMe}_{3}$ ), 0.22 (s, 6 H , $\mathrm{SiMe}_{2}$ ), and 3.37 (s, $\left.3 \mathrm{H}, \mathrm{OMe}\right)$; IR $(\mathrm{NaCl}) 2085(\mathrm{C}=\mathrm{C}=\mathrm{O})$ and $1090 \mathrm{~cm}^{-1}$ (SiOC); mass spectrum, $m / e 202\left(\mathrm{M}^{+}\right)$.
(6) Compound 7: NMR (CCl ${ }_{4}$, $\delta$ ) 0.11 (s, $9 \mathrm{H}, \mathrm{SiMe}_{3}$ ), $0.14(\mathrm{~s}, 3 \mathrm{H}$, SiMe), 0.18 ( $s, 3 \mathrm{H}, \mathrm{SiMe}$ ), 1.70 (s, $1 \mathrm{H}, \mathrm{SiCH}$ ), 3.41 ( $\mathrm{s}, 3 \mathrm{H}$, OMe), and 3.56 ( $\mathrm{s}, 3 \mathrm{H}$, OMe).
(7) Compound 8: NMR ( $\left.\mathrm{CCl}_{4}, \delta\right) ; 0.11$ (s, $9 \mathrm{H}, \mathrm{SiMe}_{3}$ ), 0.15 (s, 3 H , $\mathrm{SiMe}), 0.18(\mathrm{~s}, 3 \mathrm{H}, \mathrm{SiMe}), 1.13\left(\mathrm{t}, 3 \mathrm{H}, \mathrm{OCCH}_{3}\right), 1.20\left(\mathrm{t}, 3 \mathrm{H}, \mathrm{OCCH}_{3}\right)$, $1.66(\mathrm{~s}, 1 \mathrm{H}, \mathrm{SiCH}), 3.66\left(\mathrm{q}, 2 \mathrm{H}, \mathrm{OCH}_{2}\right)$, and $4.02\left(\mathrm{q}, 2 \mathrm{H}, \mathrm{OCH}_{2}\right)$.
(8) Compound 10: NMR (CCl $\left.{ }_{4}, \delta\right) 0.09\left(\mathrm{~s}, 9 \mathrm{H}, \mathrm{SiMe}_{3}\right), 0.13(\mathrm{~s}, 3 \mathrm{H}$, $\mathrm{SiMe}), 0.17(\mathrm{~s}, 3 \mathrm{H}, \mathrm{SiMe}), 1.21\left(\mathrm{t}, 3 \mathrm{H}, \mathrm{OCCH}_{3}\right), 1.67(\mathrm{~s}, 1 \mathrm{H}, \mathrm{SiCH}), 3.38$ (s, $3 \mathrm{H}, \mathrm{OMe}$ ), and $4.00\left(\mathrm{q}, 2 \mathrm{H}, \mathrm{OCH}_{2}\right)$. The structure of 10 was also confirmed by the exchange reaction of the methoxy group on silicon atom with alcohols.
(9) (tert-Butoxydimethylsilyl)(trimethylsilyl)ketene: NMR ( $\left.\mathrm{CCl}_{4}, \delta\right) 0.21$ ( $\mathrm{s}, 9 \mathrm{H}, \mathrm{SiMe}_{3}$ ), $0.28\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{SiMe}_{2}\right.$ ), and 1.27 (s, $9 \mathrm{H}, t \mathrm{Bu}$ ); IR ( NaCl ) 2080 $\left(\mathrm{C}=\mathrm{C}=\mathrm{O}\right.$ ) and $1045 \mathrm{~cm}^{-1}$ ( SiOC ); mass spectrum, $m / e 244\left(\mathrm{M}^{+}\right)$. Ethyl $\alpha$-(tert-butoxydimethylsilyl)- $\alpha$-(trimethylsilyl)acetate: NMR (CCl $4, \delta) 0.10$ ( $\mathrm{s}, 9 \mathrm{H}, \mathrm{SiMe}_{3}$ ), 0.18 (s, $3 \mathrm{H}, \mathrm{SiMe}$ ), 0.23 (s, $3 \mathrm{H}, \mathrm{SiMe}$ ), 1.20 (t, 3 H , $\left.\mathrm{OCCH}_{3}\right), 1.24(\mathrm{~s}, 9 \mathrm{H}, t \mathrm{Bu}), 1.62(\mathrm{~s}, 1 \mathrm{H}, \mathrm{SiCH})$, and $3.97\left(\mathrm{q}, 2 \mathrm{H}, \mathrm{OCH}_{2}\right)$.

room temperature $0 \% \quad 23 \%$
70\% 83\%

Most convincingly, silene 9 can be trapped with carbonyl compounds. Silenes are known to react with carbonyl compounds to give alkenes or silyl enol ethers through the intermediacy of labile 1,2 -silaoxetanes. ${ }^{10}$ Photolysis of $4(0.82 \mathrm{mmol})$ containing excess amounts of cyclohexanone ( 58 mmol ) gave silyl enol ether $11^{11}$ in $30 \%$ yield and ketene 5 in $53 \%$ yield. The silyl enol ether

11
11 is obtained probably by isomerization of a 1,2 -silaoxetane via $\mathrm{C}-\mathrm{C}$ bond cleavage. ${ }^{10}$ However, the reaction in acetone or 2,3-dimethyl-1,3-butadiene gave only the ketene 5 due to their low reactivities.

In summary, it is now clear that the silene having an ester group rearranges to the alkoxysilylketene 5 by migration of the alkoxy group to silicon. The intermediate silene was successfully trapped by alcohols and a carbonyl compound.
