concentrations, where the conditions permitted loss of olefin in the oxygen stream. When benzene was the solvent, the yield of phenyl benzoate was between 29 and $45 \%$, with biphenyl in approximately 5\% yield.

Table I shows the results of VPC analyses of a series of ben-zil-sensitized photoepoxidations in benzene as solvent. Table II gives the corrected results in benzene for epoxidations of five olefins previously reported. ${ }^{3}$

There is an extreme variation of about twofold in the epoxide yields from norbornene in benzene over a range of concentrations in our two laboratories. The experimental condition most difficult to standardize is the light source; in a series of experiments ${ }^{1}$ in methylene chloride, the light source was varied from a projection lamp $(48 \mathrm{~h}$, (epoxide) $/($ benzil consumed $)=0.42$ ) to a $450-\mathrm{W}$ Hanovia arc with a Corning 3387 filter, $\lambda_{\max } 436-466 \mathrm{~nm}$ ( 5.25 $\mathrm{h},($ epoxide $) /($ benzil consumed $)=1.11)$. Irradiation with the latter lamp with a potassium chromate filter, $\lambda_{\max } 313 \mathrm{~nm}$, for 0.75 h consumed $10.6 \%$ of the benzil but yielded no epoxide.

## Experimental Section

The irradiations in benzene were carried out at temperatures between 7 and $10^{\circ} \mathrm{C}$, with oxygen being constantly bubbled through the solution.

Vapor chromatography was carried out with hexadecane ${ }^{1}$ or diphenylmethane $^{2}$ as internal standard on a $5-\mathrm{ft} 5 \%$ SE- 30 column ${ }^{1}$ or a $1-\mathrm{m} 25 \%$ SE- 30 column on Chromosorb W 60-80 mesh). ${ }^{2}$ The light source was a Hanovia' or Eiko-sha ${ }^{2} 450$-W lamp in a Pyrex jacket.

In addition to the products mentioned above, the norbornene epoxidations ${ }^{2}$ yielded about $4 \%$ of a product with longer retention time than benzil and with IR and ${ }^{\prime} \mathrm{H}$ NMR spectra suggesting a norbornanediol monobenzoate: IR (neat) 3470 (br), 1720, 1705, 1205, 1110, 780, 750, $700 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CCl}_{4}\right) \delta 0.8-2.7$ (br m ), 3.7-4.8 (br m), 7.0-7.6 (m), 7.7-8.2 (m); ratio ca. 5:1:1.5:1.

## Conclusions

The present results confirm ${ }^{4}$ that no chain character is inherent in the benzil-sensitized epoxidation reaction. However, a number of facts about this and related processes bear witness to the occurrence of competing reactions: the self-sensitized photoepoxidation of methoxymethylenefluorene, ${ }^{5}$ the frequent competition of epoxidation with singlet oxygen reactions, and the general capability of benzophenone as an epoxidation sensitizer. Most of these competing processes are not understood, and they cannot be accounted for as incidental to a simple epoxidation by benzoylperoxy radicals. The authors concerned ${ }^{3}$ deeply regret having made an erroneous report in this field, and efforts are being continued to arrive at a comprehensive view of the process.

# Reactivities of Norbornene-Type Double Bonds in Propellane Derivatives and Their Precursors; Furan as a Diene 

Paul D. Bartlett,* Gerald L. Combs, Jr., Ai-Xuan Thi Le, William H. Watson, ${ }^{* 1}$ Jean Galloy, ${ }^{1}$ and Michio Kimura ${ }^{1}$<br>Contribution from the Department of Chemistry, Texas Christian University, Fort Worth, Texas 76129. Received November 9, 1981

#### Abstract

Some of the factors determining reactivity of a norbornenic double bond have been investigated by measuring the rates of epoxidation of the syn and anti adducts ( $\mathbf{3}$ and 4) of cyclopentadiene to norbornene-2,3-dicarboxylic anhydride, the syn adduct 10 of furan to the same dienophile, and the anti adduct 5 of cyclopentadiene to norbornadiene-2,3-dicarboxylic anhydride. In this series the major determinant of double-bond reactivity is proximity in space to the anhydride group. Structures of the monounsaturated syn and anti adducts 10 and 15 , the anti cyclopentadiene adduct 4 , and its epoxide $\mathbf{6}$ have been determined by X-ray crystallography. In additions to dienophiles $\mathbf{1}$ and $\mathbf{2}$, the use of furan rather than cyclopentadiene strongly favors the exo Alder's rule products 13 and 10.

The effect of bicyclic ring structures, notably that of norbornene, on the reactivity of the double bond has been of interest for some time. ${ }^{2}$ In this rigid system the angle strain and positions in space of neighboring groups can be precisely specified and correlations sought with the observed rates of reaction. ${ }^{3}$ In a growing number

atoms may account for specific endo or exo directive effects as well as general reactivity and, in some cases, special geometry of the double bond.

The first synthesis of anti-sesquinorbornene ${ }^{14}$ and also previous work beginning with a similar synthesis ${ }^{3}$ involved some striking stereoselectivities in Diels-Alder reactions leading predominantly to the propellanes $3-5$ and 11 , and some very tight classical steric hindrance in the syn-propellane anhydrides ( 3 and its hydrogenation product) (see Chart I).

Specifically, in the addition of cyclopentadiene to nor-bornene-2,3-dicarboxylic anhydride (2), comparable amounts of the Alder's rule and anti-Alder's rule adducts 3 and 4 were obtained, ${ }^{14}$ representing an increase in the Alder/anti-Alder product ratio of over 40 -fold compared to the reaction with the doubly unsaturated anhydride 1. ${ }^{3}$ These results were independent of whether alumina was used to catalyze the addition, ${ }^{14}$ and no time dependencies of the product ratio were observed.

We have now found that the use of furan instead of cyclopentadiene leads to a $20 ; 1$ ratio of the Alder's rule product $\mathbf{1 0}$ to the anti-Alder's rule product $\mathbf{1 5}$ from anhydride 2 . In the case of the doubly unsaturated anhydride $\mathbf{1}$, furan added to yield the Alder's rule product 13 in high yield with no detectable presence of a second isomer. Toward the typical dienophile maleic anhydride, furan has been observed not only to be a less reactive diene than cyclopentadiene but also to yield Alder's rule products reversibly, which during prolonged reaction are converted into the more thermodynamically stable exo isomers. ${ }^{20}$ In the present

[^1]instance no reversibility could be detected in the formation of either $\mathbf{1 0}$ or 13. It would appear that Alder's rule is not dominant (either positively or negatively) in determining the thermodynamic stability of the product, a more important factor here being the interaction between the $\mathrm{CH}_{2}$ and O bridges, which could operate similarly in transition state and product.

The structures of 10 and 15 were determined by X-ray crystallography; that of $\mathbf{1 3}$ was established by the fact that it and $\mathbf{1 0}$ were quantitatively hydrogenated to the same saturated anhydride 14.

The forces which operate in Alder's rule are the initial do-nor-acceptor interactions between the $\pi$ systems of diene and dienophile, both $\pi$ systems being normally coplanar. As the immediate sequel to this interaction, $\sigma$ bonding develops, this process being rapid enough so that the Diels-Alder reaction is classified as having an early transition state, ${ }^{23}$ with no energy minimum corresponding to an initial $\pi$ complex. In the addition of cyclopentadiene to anhydride 1 or 2 the initial approach geometry must be displaced from the ideal Alder parallel-plane configuration by the spatial conflict between the $\mathrm{CH}_{2}$ of the cyclopentadiene and the methylene bridge of the dienophile. The feasibility of a smooth Alder addition thus depends on (a) the possible resolution of this hindrance in the new geometry of the product and (b) the existence of a reaction path in which the initial and final bonding forces can merge into each other without being too much weakened by the steric forces at an intermediate stage.

It is obvious that the relative rates of Alder and anti-Alder additions in the present system depend critically on the balance of these forces. As far as the difference between cyclopentadiene and furan is concerned, the repulsive interaction beween $\mathrm{CH}_{2}$ and $\mathrm{CH}_{2}$ in the Alder transition state may well be replaced by a mildly attractive interaction between $\mathrm{CH}_{2}$ and the O of furan. This interaction, which must begin in the orientation of the initial approach, is still evident in the dimensions of the final product: a less-than-favorable $\mathrm{H}_{9}-\mathrm{H}_{10}$ distance of $1.80 \AA$ in 3 , and a corresponding $\mathrm{H}-\mathrm{O}$ distance in 10 of $2.20 \AA$, which might well represent more of an energy minimum.
The difference between dienophiles 1 and 2 may be more complicated, since the remote double bond favors anti-Alder addition of cyclopentadiene but Alder addition of furan. If we are near the critical energies for these two modes of addition, it could well be that a small additional force displacing the methylene bridge of 1 toward the anhydride group might have this effect, destabilizing the Alder's rule transition state for cyclopentadiene but stabilizing it for furan. Forces have been noted in recent studies of syn-sesquinorbornene ${ }^{10,21}$ that might cause the remote double bond to exert a force in this direction.

In endo-1,4-exo-5,8-dimethano-cis-1,4,4a,5,6,7,8,8a-octahydronaphthalene, the parent hydrocarbon of 4 , the reactivity of the 2,3 double bond as affected by substituents on the neighboring methylene bridge has been the subject of careful study. ${ }^{24}$ The rate of peracid epoxidation was increased 13 -fold by a cis-methoxy group on the neighboring bridge, and decreased 25 -fold when the bridge group was carbonyl instead of methylene. Similar effects were observed on $(2+4)$ cycloadditions. In these norbornenic systems, the epoxidation always occurred on the exo face of the double bond. However, in [4.4.3]propellenes, with unbridged rings, the steric forces are sufficiently balanced so that, depending on the substituents on the five-membered ring, epoxidation occurs on both faces of the double bond. ${ }^{25}$

We undertook to compare the reactivities of the double bonds in the series $\mathbf{3}, 4,5,7,8$ and 10 toward $m$-chloroperbenzoic acid (MCPBA) as a measure of the effect of including the anhydride

ring in the system. For the purpose of comparisons of reactivity, rate studies were made under the same experimental conditions for $\mathbf{3}, \mathbf{4}, 5$, and 10 . Solutions 0.02 M in both the olefin and MCPBA in methylene chloride were prepared by dissolving at $0^{\circ} \mathrm{C}$ and warmed to $25^{\circ} \mathrm{C}$, and samples were taken over periods of $50-100 \mathrm{~h}$. The ratio of epoxide to unreacted hydrocarbon was determined by quenching the aliquots with $10 \%$ sodium bisulfite solution and analyzing by vapor phase chromatography with hexadecane as internal standard. Authentic samples of the epoxides 6, 7, 9, 12, and 16 were prepared and characterized as described in the Experimental Section. Due to difficulties in isolating a pure sample of epoxide 8 , this compound was characterized solely by its mass spectrum, which was identical in many respects with that of the isomeric epoxide 7. Also it was found that upon further treatment of a mixture of $\mathbf{7}$ and $\mathbf{8}$ with MCPBA, these were converted completely to the diepoxide 9. A clear distinction between the structures of isomeric 7 and 8 was possible when it was found that upon hydrogenation, 7 could be converted quantitatively to 6 .

Conveniently, when the reactants are at equal concentrations, the fraction ( $e / x x_{0}$ ) is equal to $k t$, where $e=$ [epoxide], $x=$ [olefin] at time $t$, and $x_{0}=$ initial olefin concentration. Plots of this fraction against time for the four propellanes $\mathbf{3 , 4 , 5}$, and 10 were linear over the entire time interval, with correlation coefficients of $0.995-0.999$, leading to the bimolecular rate constants listed in Table I.

Both double bonds of $\mathbf{5}$ react simultaneously, but the product analysis indicates that the reaction of one of them predominates over the other by a factor of about 9 . This accounts for the fact that, over the $60 \%$ reaction of 5 observed, the small departure from the $1: 1$ ratio of consumption of reactants does not cause an appreciable deviation from linearity of the plot.

The epoxide 6 was apparently a minor contaminant in the olefin 4. As with other mildly strained olefins, ${ }^{15,16}$ propellanes 3,4 , and 5 could all be epoxidized by molecular oxygen initiated by azobis(isobutyronitrile) (AIBN), but the uninitiated rate was too low for convenient measurement. Nevertheless, there was evidence that the sample of 5 used in the kinetic study, in the course of recrystallization, had undergone some conversion to the epoxide 7: the concentrations of 5 extrapolated not to the intended initial 0.0248 M but to 0.0189 M . The missing 0.0059 M , if assumed to be 7, fitted smoothly on the curve of its concentrations determined by vapor chromatography. These corrected initial

Figure 1. Calculated and observed concentrations of 5, 7, 8, and 9 in the epoxidation run of Table II. Observed values: 5 , circles; 7 , pentagons; 8, squares; 9, triangles. Lines are calculated values assuming the initial concentrations and rate constants of Table 11, footnote $a$.
concentrations were taken into account in the calculations leading to the assignment of the four rate constants involved in this system.

For estimates of the four rate constants actually involved in the reaction of MCPBA with 5 , a series of aliquots were taken and a nalyzed with respect to the three epoxides 7,8 , and 9 , as well as the starting hydrocarbon. It is seen from Figure 1 that the slowly forming epoxide 8 , having a relatively reactive double bond, reaches a steady-state concentration after 46 h , at about $70 \%$ reaction, while the other epoxides continue to increase slowly throughout the period of observation. The data from these analyses allowed a set of successive approximations to the values of the rate constants, which were tested by incremental calculations on a computer; the values of time and concentrations of $\mathbf{5}, \mathbf{7}, \mathbf{8}$, and 9 were calculated from the differential rate equations for 148 successive points along the reaction course, the assumed values of the rate constants being adjusted on the basis of the fit of each run to the experimental values of these concentrations. The selected values of the rate constants are shown in Table II, and the incrementally calculated concentrations are shown by the curves in Figure 1 and compared with the analytical values.

A test calculation showed that the course of a model secondorder reaction with $x_{0}=0.0189 \mathrm{M}$ and $k=1.35 \mathrm{M}^{-1} \mathrm{~h}^{-1}$ could

[^3] $k_{7}=1.39 \times 10^{-5} ; k_{8}=3.0 \times 10^{-4} \mathrm{M}^{-1} \mathrm{~s}^{-1} .{ }^{b}$ By vapor phase chromatography.

Figure 2. ORTEP drawing of compound 4. The ellipsoids are drawn at the $35 \%$ probability level while the hydrogen atoms are represented by spheres of arbitrary size.

Figure 3. Drawing of compound 6. The ellipsoids are drawn at the $35 \%$ probability level while the hydrogen atoms are represented by spheres of arbitrary size.
be calculated incrementally with 160 points over $84 \%$ of its course, matching the concentrations from the integrated rate equation within a maximum error of 0.00005 M , or $0.26 \%$ of $x_{0}$.

It can be seen from Table I that of the seven double bonds whose reactivities were observed, those syn to an anhydride group showed epoxidation rate constants between 1.4 and $4.2 \times 10^{-5} \mathrm{M}^{-1} \mathrm{~s}^{-1}$, while the double bonds syn to a methylene bridge were an order of magnitude more reactive, with $k$ 's of $(30-68) \times 10^{-5}$. As would be expected from the work of Paddon-Row et al. ${ }^{24}$ the anhydride ring is the only important influence on the reactivity of these double bonds. The factor of $9-19$ by which its presence depresses the epoxidation rate in anti structures is less than the factor of 25 previously observed for a carbonyl bridge, ${ }^{24}$ a normal result of the anhydride oxygen atom delocalizing the charge on the carbonyl carbon atoms.

Figures 2, 3, 4, and 5 are ORTEP drawings ${ }^{17}$ of compounds 4, 6, 10, and 15, while Tables III and IV present interatomic distances and valence angles. Figures 6 and 7 show important interplanar angles and intramolecular contacts. Although the hydrogen atom positions are not located accurately, the hydrogen atoms on $C(2)$ and $C(3)$ in compounds $3,{ }^{14} 4,10$, and 15 appear to be bent away from the methylene and oxo bridges by $3^{\circ}, 6^{\circ}, 4^{\circ}$, and $1^{\circ}$, respectively. While any single observation might be questionable, the consistent bending of the hydrogen atoms away from the methylene or oxo bridge is significant.

The exclusive exo epoxidation observed here is consistent with steric hindrance to endo attack since $\mathrm{H}(9 \mathrm{en})-\mathrm{C}(2,3)=2.48 \AA$ and $2.43 \AA$ in 4 and 15 while $C(2,3)-C(11,12)=2.77 \AA$ and 2.72

Figure 4. ORTEP drawing of compound 10. The ellipsoids are drawn at the $35 \%$ probability level while the hydrogen atoms are represented by spheres of arbitrary size.

Figure 5. ORTEP drawing of compound 15. The ellipsoids are drawn at the $35 \%$ probability level while hydrogen atoms are represented by spheres of arbitrary size.
$\AA$ in $\mathbf{1 0}$ and 3. The central interplanar angle is $129.3^{\circ}$ in $\mathbf{1 5}$, $128.4^{\circ}$ in $\mathbf{4}, 125.7^{\circ}$ in $\mathbf{3}$, and $122.7^{\circ}$ in $\mathbf{1 0}$. The closest approaches to $\mathrm{H}(9 \mathrm{en})$ for the three compounds are $\mathrm{H}(9 \mathrm{en})-\mathrm{H}(10 \mathrm{en})=1.80$ $\AA$ in $3, \mathrm{H}(9 \mathrm{en})-\mathrm{O}(10)=2.20 \AA$ in 10 , and the distance from $\mathrm{H}(9 \mathrm{en})$ to the center of the $\mathrm{C}(2)-\mathrm{C}(3)$ double bond of $2.34 \AA$ in 15 and $2.40 \AA$ in 4 . The reduction in the central interplanar angle upon going from $\mathbf{3}$ to 10 is readily understood; however, the larger angle in $\mathbf{4}$ and 15 may result from $H(9 e n)-\pi$-cloud repulsion or reduced repulsion between the anhydride and the methylene or oxo bridges.

The exo faces of the double bonds are sterically accessible and the greater reactivity of $\mathbf{4}$ and $\mathbf{1 5}$ compared to $\mathbf{3}$ and 10 must be attributed to other factors. The carbon atoms $\mathrm{C}(11)$ and $\mathrm{C}(12)$ lie an average of 2.72 and $2.77 \AA$ from the carbon atoms $C(2)$ and $C(3)$ in $\mathbf{3}$ and 10. The close proximity and suitable orientation of orbitals ensures significant overlap of the $\pi$ system and together with partial positive charges on the carbonyl carbon atoms must lead to significant orbital modification. The nature of the $\pi$ system in which the double bond is syn to the anhydride differs significantly from the isolated ethylenic $\pi$ system in compounds where the methylene is anti to the anhydride. A series of low-temperature X -ray and neutron diffraction experiments has been initiated to investigate $\pi$-electron distributions and the accurate location of hydrogen atom positions.

## Experimental Section

Preparations. Dimethyl acetylenedicarboxylate, furan, dicyclopentadiene, and $m$-chloroperbenzoic acid were obtained from Aldrich Chemical Co. Ethoxyacetylene was obtained from Pfaltz and Bauer.

Figure 6. Important interplanar angles (deg) and intramolecular contacts $(\AA)$ for compounds $\mathbf{3}^{14}$ (top), 4 (middle), and 10 (bottom).

The solvents were spectral grade from Aldrich Chemical Co. The silica gel used in the Diels-Alder reactions was $60 \mathrm{Pf}-254$ for preparative chromatography by EM reagents and obtained from Brinkmann. The silica gel used for column chromatography separations was 60-200 mesh obtained from Baker Chemical Co. The neutral aluminum oxide used in isomer separation was activity grade 1 manufactured for ICN Nutritional Biochemicals by Woelm Pharma. Benzene was distilled over sodium. Cyclopentadiene was from freshly cracked dicyclopentadiene. Mass spectra were obtained with a Finnigan OWA-1020 GC-MS-DS. NMR spectra were obtained with JEOL-FX60 and Varian EM-390 NMR spectrometers in $\mathrm{CDCl}_{3}$ with internal $\mathrm{Me}_{4} \mathrm{Si}$ as reference unless otherwise noted. Gas chromatographic analyses during kinetic reactions were done on a Perkin-Elmer Sigma 3 gas chromatograph apparatus with a 6 -ft 5\% SE-30 column. IR spectra were taken on a Perkin-Elmer 197 infrared spectrophotometer. Melting points were uncorrected and were taken on a Hoover capillary melting point apparatus. The anhydrides $\mathbf{1 , 5}$, and 11 were prepared according to the previously described method of Edman and Simmons. ${ }^{3}$ Anhydrides 2, 3, and 4 were prepared according to Bartlett, Blakeney, Kumura, and Watson. ${ }^{14}$

1,2,3,4,4a,5,8,8a-Octahydro-5,8-exo-oxa-1,4-exo-methano-naphthalene-4a,8a-dicarboxylic Anhydride (10) and 1,2,3,4,4a,5,8,8a-Octahydro-5,8-endo-oxa-1,4-exo-methanonaphthalene-4a,8a-dicarboxylic Anhydride (15). Norbornene-2,3-dicarboxylic anhydride (2) (7.94 g, 48 mmol ) was dissolved in 100 mL of furan ( $95 \mathrm{~g}, 1.40 \mathrm{~mol}$ ) and the solution

Figure 7. Important interplanar angles (deg) and intramolecular contacts ( $\AA$ ) for the two independent molecules of 6 and 15 (bottom).
stirred under nitrogen for 24 h at room temperature. The excess furan was removed (rotavap) and the resulting yellow solid was chromatographed repeatedly on a silica gel column, followed by thin-layer chromatography on silica gel, methylene chloride being the eluent in both cases. Chromatography separated 10 and 15 in relative amounts of 20:1.

10 is a white solid: $\mathrm{mp} 146-147{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR $\delta 6.42$ ( $\mathrm{br} \mathrm{s}, 2 \mathrm{H}$ ), 4.98 (br s, 2 H), 2.76 (br s, 2 H ), 1.8-1.2 (m, 6 H ); ${ }^{13} \mathrm{C}$ NMR $\delta 170.55$, 137.42, 82.71, 67.18, 41.52, 39.57, 26.44; IR (KBr disk) 1857 and 1777 $\mathrm{cm}^{-1}$.
$\mathbf{1 5}$ is a white solid: $\mathrm{mp} 145-146{ }^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR $\delta 6.50(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 5.23$ (br s, 2 H ), 2.52 (br s, 2 H ), 1.8-1.1 (m, 6 H ); ${ }^{13} \mathrm{C}$ NMR $\delta 173.22$, 137.36, $84.08,67.44,38.40,37.88,27.68$; IR ( KBr disk) $1853,1775 \mathrm{~cm}^{-1}$.

In another preparation, heated under reflux for 18 h , the combined yield of 10 and 15 was $96 \%$.

1,4,4a,5,8,8a-Hexahydro-1,4-exo-oxa-5,8-exo-methanonaphthalene-4a,8a-dicarboxylic Anhydride (13). Norbornadiene-2,3-dicarboxylic anhydride (1) ( $100 \mathrm{mg}, 0.62 \mathrm{mmol}$ ) was dissolved in furan ( $5 \mathrm{~mL}, 70$ mmol ) and stirred under nitrogen for 18 h , and the excess furan removed. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of the crude product revealed the formation of a single isomer with no clear evidence of a second isomer. 13 is a white solid that can be recrystallized from ether: yield $97 \%$; mp 148.5-150 ${ }^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR $\delta 6.67$ (br s, 2H), 6.43 (br s, 2 H ), 5.03 (br s, 2 H ), 3.27 (brs, 2 H ), $3.03(\mathrm{~d}, 1 \mathrm{H}, J=9 \mathrm{~Hz}$ ), 1.77 (d, $1 \mathrm{H}, J=9 \mathrm{~Hz}$ ); ${ }^{13} \mathrm{C}$ NMR $\delta 170.36,141.38,139.89,81.80,72.19,49.57,46.78$; IR ( KBr disk) $1859,1759 \mathrm{~cm}^{-1}$.

${ }^{a}$ Average deviation shown in parentheses. ${ }^{b}$ Equivalent values averaged.

1, 2, 3,4,4a, 5,6,7,8,8a-Decahydro-1,4-exo-oxa-5,8-exo-methano-naphthalene-4a,8a-dicarboxylic Anhydride (14). Samples of 14 were prepared (a) by $\mathrm{Pd} /$ charcoal hydrogenation of $\mathbf{1 0}$ in a Parr shaker at 15 psi in ethyl acetate and (b) by hydrogenation of 13 with the same catalyst and apparatus at 20 psi in ethanol. Both samples of 14 had identical properties: ${ }^{1} \mathrm{H}$ NMR $\delta 4.58$ (br s, 2 H ), 2.95 (br d, 1 H ), 2.68 (br s, 2 H), 1.88 (br s, 4 H ), $1.8-1.2(\mathrm{~m}, 5 \mathrm{H})$; ${ }^{13} \mathrm{C}$ NMR $\delta 171.59,81.87,71.54$, $42.95,40.09,27.87,26.51 .14$ is a white solid (mp 161.5-163.5 ${ }^{\circ} \mathrm{C}$ ) and has IR absorptions at 1852 and $1756 \mathrm{~cm}^{-1}$ ( KBr disk).

Decahydro-2,3-exo-epoxy-1,4-endo-5,8-exo-dimethanonaphthalene-4a,8a-dicarboxylic Anhydride (6). $\mathbf{4}$ ( $0.15 \mathrm{~g}, 0.00065 \mathrm{~mol}$ ) was stirred in 10 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $0^{\circ} \mathrm{C}$. MCPBA ( $80 \%, 0.15 \mathrm{~g}, 0.00069 \mathrm{~mol}$ ) in 5 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added dropwise to the solution and the reaction flask was stirred at room temperature for 38 h . The solution was washed with sodium bisulfite ( $10 \%$ ), $10 \% \mathrm{NaHCO}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$. The organic layer was dried over $\mathrm{MgSO}_{4}$, and the solvent was removed to give a white solid. The product was recrystallized from EtOH to give a white solid: yield $81 \%$; mp $260-270{ }^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR $\delta 3.27$ (s, 2 H ), 3.06 (s, 2 H ), 2.75 ( s , $2 \mathrm{H}), 2.42(\mathrm{~d}, 1 \mathrm{H}, J=10 \mathrm{~Hz}), 1.9-1.2(\mathrm{~m}, 6 \mathrm{H}), 0.75(\mathrm{~d}, 1 \mathrm{H}, J=10$ Hz ); ${ }^{13} \mathrm{C}$ NMR $\delta 173.74,66.66,50.55,45.03,41.52,39.83,27.55,25.60$; IR ( KBr disk) $1851,1763,1213 \mathrm{~cm}^{-1}$.

Decahydro-2,3-exo-epoxy-1,4-exo-5,8-exo-dimethanonaphthalene-4a,8a-dicarboxylic Anhydride (12). MCPBA ( $80 \%, 0.47 \mathrm{~g}, 0.00218 \mathrm{~mol}$ ) in 10 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added dropwise to a stirred solution of 0.5 g ( 0.00217 mol ) of 3 in 15 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $0^{\circ} \mathrm{C}$. After 2 days of refluxing, the reaction mixture was cooled, washed with $10 \%$ sodium bisulfite, $10 \% \mathrm{NaHCO}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$, and dried over $\mathrm{MgSO}_{4} . \mathrm{CH}_{2} \mathrm{Cl}_{2}$ was evaporated to leave the crude product, which was then eluted through a silica gel column (petroleum ether-ether, 5:1) followed by recrystallization (petroleum ether-ether) to give clear needles: yield $79 \% ; \mathrm{mp}$ 198.5-200.5 ${ }^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR $\delta 3.23$ ( $\mathrm{s}, 2 \mathrm{H}$ ), 2.85 ( $\mathrm{s}, 2 \mathrm{H}$ ), 2.8-2.3 (m, 3 H), 2.2-1.3 (m, 7 H); ${ }^{13} \mathrm{C}$ NMR $\delta 172.89,68.61,48.67,43.66,42.69$, 42.36, 41.52, 26.44; IR (KBr disk) $1849,1770,1237 \mathrm{~cm}^{-1}$ ).

1,4,4a,5,6,7,8,8a-Octahydro-6,7-exo-epoxy-1,4-exo-5,8-endo-di-methanonaphthalene-4a,8a-dicarboxylic Anhydride (7) and 1,2,3,4,4a,5,8,8a-Octahydro-2,3-exo-epoxy-1,4-exo-5,8-endo-di-methanonaphthalene-4a,8a-dicarboxylic Anhydride (8). 5 ( $0.154 \mathrm{~g}, 6.7$ mmol) was dissolved in 20 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and cooled to $0^{\circ} \mathrm{C}$ while 0.145 $\mathrm{g}(6.7 \mathrm{mmol})$ of $80 \%$ MCPBA in 7 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added dropwise to the stirred solution. The mixture was left stirring at room temperature.

At $94 \%$ completion of the reaction, the products were found to be 20.3:1:2.3 of $7: 8: 9$ by VPC. The mixture was then washed with $10 \%$ sodium bisulfite, $10 \% \mathrm{NaHCO}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$ and dried ( $\mathrm{MgSO}_{4}$ ), and the solvent was removed (rotavap). Analysis of the crude reaction mixture by GC-MS demonstrated the very close similarity of the epoxides 7 and 8: mass spectra, $m / z, 7244$ (1), 226 (2.5), 172 (19), 143 (39), 128 (70.6), 115 (47), 105 (15.4), 91 (12.6), 66 (100); mass spectra, $m / z, 8$ 244 (3), 226 (1.1), 143 (8.6), 128 (27.3), 115 (18.7), 105 (4.8), 91 (10.5), 66 (100).

Repeated recrystallization of the crude product from acetone-etherpetroleum ether gave pure 7, a white solid: $\mathrm{mp} 268-280^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR $\delta 6.43$ (s, 2 H), 3.31 (s, 2 H), 3.23 (s, 2 H), 3.03 (s, 2 H), 2.55 (d, 1 H, $J=10 \mathrm{~Hz}), 1.9-1.5(\mathrm{~m}, 2 \mathrm{H}), 1.14(\mathrm{~d}, 1 \mathrm{H}, J=10 \mathrm{~Hz}) ;{ }^{13} \mathrm{C}$ NMR $\delta$ 173.09, 141.71, 67.44, 50.74, 50.48, 45.03, 43.08, 29.76; IR (KBr disk) 1850, 1771, $1222 \mathrm{~cm}^{-1}$.
Further proof of the exact structure of 7 came by hydrogenation of 7 in a Parr shaker apparatus with $5 \% \mathrm{Pd} /$ charcoal catalyst in EtOAc at 5 psi $\mathrm{H}_{2}$. After filtration through Celite and removal of the solvent, the remaining white solid was found to be identical in all respects $\left({ }^{13} \mathrm{C}\right.$ and ${ }^{1} \mathrm{H}$ NMR, mp ) with a sample of 6 .

Decahydro-2,3-exo-6,7-exo-diepoxy-1,4-exo-5,8-endo-dime thano-naphthalene-4a,8a-dicarboxylic Anhydride (9). $5(0.158 \mathrm{~g}, 6.7 \mathrm{mmol})$ was dissolved into ice-cold $\mathrm{CH}_{2} \mathrm{Cl}_{2}(9 \mathrm{~mL})$. MCPBA ( 0.40 g of $80 \%$ ) in 10 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was added to the solution. The mixture was then refluxed for 2 days, cooled, washed with $10 \%$ sodium bisulfite, $5 \%$ of $\mathrm{NaHCO}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$, and dried with $\mathrm{MgSO}_{4} . \mathrm{CH}_{2} \mathrm{Cl}_{2}$ was removed in vacuo. The crude product was rinsed with cold chloroform and dried to give 9, a white solid: $\mathrm{mp} 330-343^{\circ} \mathrm{C}$ dec; ${ }^{1} \mathrm{H}$ NMR $\delta 3.26$ (s, 2 H ), 3.21 ( $\mathrm{s}, 2$ H), $3.04(\mathrm{~s}, 2 \mathrm{H}), 2.92(\mathrm{~s}, 2 \mathrm{H}), 1.66(\mathrm{~s}, 2 \mathrm{H}), 1.20(\mathrm{~s}, 2 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta 172.24 \mathrm{j}, 66.34,49.64,44.38,40.54,26.70,25.92,25.34 ;$ IR (KBr disk) 1852, $1770,1225 \mathrm{~cm}^{-1}$.

Decahydro-1,4-exo-oxa-2,3-exo-epoxy-5,8-exo-methanonaphthalene-4a,8a-dicarboxylic Anhydride (16). 10 ( $0.148 \mathrm{~g}, 6.4 \mathrm{mmol}$ ) was dissolved in 10 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and to this solution was added dropwise 0.145 g ( 6.7 mmol ) of $80 \%$ MCPBA in 7 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The resulting solution was refluxed while being stirred for 5 days, cooled, washed with $10 \%$ sodium bisulfite, $5 \% \mathrm{NaHCO}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$, and dried ( $\mathrm{MgSO}_{4}$ ), and the solvent was removed (rotavap). Recrystallization of the residue from acetone-ether-petroleum ether gave a white solid: $\mathrm{mp} 170-174^{\circ} \mathrm{C}$; yield $80 \%$; ${ }^{1} \mathrm{H}$ NMR $\delta 4.57$ ( $\mathrm{s}, 2 \mathrm{H}$ ), 3.48 ( $\mathrm{s}, 2 \mathrm{H}$ ), 2.73 (br s, 2 H ), 1.8-1.0 (m, 6

H); ${ }^{13} \mathrm{C}$ NMR $\delta 169.90,78.75,71.28,47.43,42.75,40.61$, and 26.25 ; IR ( KBr disk) $1855,1771,1232 \mathrm{~cm}^{-1}$.

X-ray Analysis. All X-ray data were collected on a Syntex $\mathrm{P} 2_{1}$ diffractometer system with graphite-monochromated $\mathrm{Cu} \mathrm{K} \alpha(\lambda=1.54178$ $\AA$ ) or Mo $\mathrm{K} \alpha(\lambda=0.71069 \AA$ ) radiation (in the case of 6 ). Roomtemperature lattice parameters were refined by a least-squares procedure utilizing 15 reflections whose angles were measured by a centering routine associated with the Syntex diffractometer. Intensity data were collected by the $\theta-2 \theta$ scanning technique, using a variable scan speed with a maximum $2 \theta$ of $115^{\circ}$ for compound $4,120^{\circ}$ for compounds 6 and $\mathbf{1 0}$, and $130^{\circ}$ for compound 15 . Periodically monitored reflections showed no significant changes in intensities. The data were corrected for Lorentz and polarization factors, but no absorption corrections were applied. The direct methods program mULTAN78 ${ }^{18}$ was used to solve all structures. The structures were refined by a full-matrix least-squares technique with anisotropic thermal parameters for the nonhydrogen atoms.

The refinements were terminated when the average shift was of the order of one-tenth of the average esd. The $R$ factor is defined as $R=$ $\sum\left|\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}} \| / \sum\right| F_{\mathrm{o}}\right|$. The function minimized was $\sum \omega\left(\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$, where $\omega=1 / \sigma^{2}\left(F_{0}\right)$ or $1 /\left[\sigma^{2}\left(F_{0}\right)+\left(0.01 F_{0}\right)^{2}\right]$. Scattering factors were calculated by the XRAY76 ${ }^{19}$ program. Tables of atomic positional parameters, anisotropic thermal parameters, and observed and calculated structure factors are included in the supplementary material.

Compound 4. A crystal of dimensions $1.3 \times 0.75 \times 0.3 \mathrm{~mm}$ was used to collect all data. The unit cell is triclinic, and statistics and structure solution indicated space group $P \overline{1}$.

Crystal Data. $\mathrm{C}_{14} \mathrm{H}_{14} \mathrm{O}_{3}: \quad M_{\mathrm{r}}=230.3, a=7.164$ (2) $\AA, b=8.289$ (2) $\AA, c=10.145$ (2) $\AA, \alpha=96.30(2)^{\circ}, \beta=92.22(2)^{\circ}, \gamma=111.90$ (2) ${ }^{\circ}, V=553.5$ (3) $\AA^{3}, Z=2, d_{\mathrm{C}}=1.38 \mathrm{~g} \mathrm{~cm}^{-3}, \mu=7.99 \mathrm{~cm}^{-1}$. Of the 1491 independent reflections measured with $\mathrm{Cu} \mathrm{K} \alpha$ radiation, 1291 had intensities greater than $3 \sigma(I)$. Phases were calculated for the $282|E|$ values greater than 1.3, and the phase set with highest combined figure of merit yielded an $E$ map that revealed the positions of all nonhydrogen atoms. Full-matrix least-squares refinement reduced the $R$
factor to 0.131 . All hydrogen atoms were located in a difference map and further least-squares refinement led to a final $R$ of 0.084 .

Compound 6. Crystals of the epoxide were of very poor quality. A crystal of dimensions $0.30 \times 0.20 \times 0.50 \mathrm{~mm}$ was used for all data collection. The unit cell is monoclinic and systematic absences were consistent with space group $P 2_{1} / a$.

CrystaI Data. $\mathrm{C}_{14} \mathrm{H}_{14} \mathrm{O}_{4}: M_{\mathrm{r}}=246.3, a=14.578$ (7) $\AA, b=12.186$ (4) $\AA, c=14.599(10) \AA, \beta=119.22(4)^{\circ}, V=2263$ (2) $\AA^{3}, Z=8, d_{\mathrm{c}}$ $=1.445 \mathrm{~g} \mathrm{~cm}^{-3}, \mu=8.89 \mathrm{~cm}^{-1}$; two independent molecules per asymmetric unit.

Of the 3812 independent reflections measured with Mo $\mathrm{K} \alpha$ radiation, 2114 had intensities greater than $2 \sigma(I)$. Phases were calculated for the $200|E|$ values greater than 1.4, and the phase set with the highest combined figure of merit revealed the positions of 34 nonhydrogen atoms. Alternate least-squares refinements and difference Fourier calculations led to the location of the remaining atoms of the two independent molecules. Full-matrix least-squares refinement led to a final $R$ factor of 0.088 .

Compound 10. The unit cell is monoclinic and systematic extinctions were consistent with space group $P 2_{1} / c$.

Crystal Data. $\mathrm{C}_{13} \mathrm{H}_{12} \mathrm{O}_{4}: M_{\mathrm{r}}=232.2, a=15.982$ (8) $\AA, b=7.564$ (2) $\AA, c=12.084$ (4) $\AA, \beta=134.44(2)^{\circ}, V=1042.9(6) \AA^{3}, Z=4$, $d_{\mathrm{c}}=1.48 \mathrm{~g} \mathrm{~cm}^{-3}, \mu=9.29 \mathrm{~cm}^{-1}$.

Of the 1407 independent reflections measured, 1124 had intensities greater than $3 \sigma(I)$. Phases were calculated for the $262|E|$ values greater than I.30, and the phase set with the highest combined figure of merit yielded an $E$ map that revealed the positions of all nonhydrogen atoms. Full-matrix least-squares refinment led to an $R$ of 0.133 . All hydrogen atom positions were located in a difference map. A total of 14 strong reflections were eliminated because of extinction. Further least-squares refinement led to a final $R$ of 0.087 .

Compound 15. A crystal of dimensions $0.30 \times 0.22 \times 0.17 \mathrm{~mm}$ was used for all data collection. The unit cell is monoclinic and systematic absences were consistent with space group $P 2_{1} / c$.

Crystal Data. $\mathrm{C}_{13} \mathrm{H}_{12} \mathrm{O}_{4}: M_{\mathrm{r}}=232.2, a=11.472$ (2) $\AA, b=7.635$ (2) $\AA, c=12.260$ (1) $\AA, \beta=96.72$ (1),$V=1066.4$ (4) $\AA^{3}, Z=4, d_{c}$ $=1.45 \mathrm{~g} \mathrm{~cm}^{-3}, \mu=9.09 \mathrm{~cm}^{-1}$

Of the 1773 independent reflections collected, 961 had intensities greater than $3 \sigma(I)$. Phases were calculated for the $191|E|$ values greater than 1.20 and the phase set with highest combined figure of merit yielded an $E$ map that revealed the positions of all nonhydrogen atoms. After anisotropic refinement, all hydrogen atoms were located in a difference map. An isotropic extinction correction ${ }^{22}$ introduced in the last cycles of refinement refined to a value of $11.8(2) \times 10^{-3}$ and yielded a final $R$ factor of 0.035 .

# $o$-Carboranylcarbene and $m$-Carboranylcarbene ${ }^{1,2}$ 

Sarangan L. Chari, Sheau-Hwa Chìang, and Maitland Jones, Jr.*<br>Contribution from the Department of Chemistry, Princeton University, Princeton, New Jersey 08544. Received July 30, 1981

#### Abstract

Addition of $o$ - and $m$-carboranylcarbene to olefins takes place in a largely stereospecific fashion. In the addition to cis olefins, it is the anti isomer that predominates. Insertion into carbon-hydrogen bonds occurs with a secondary/primary selectivity ratio of 3.0. (Methyl-o-carboranyl)carbene behaves like tolylcarbene in intramolecular reactions. It yields vi-nyl-o-carborane and the carborane analogue of benzocyclobutene. (Methyl- $m$-carboranyl)carbene does not give vinyl- $m$-carborane.

If one were set the task of choosing the archetypal carbene, one might well settle on phenylcarbene. ${ }^{3}$ Not only are the properties of both the addition and insertion reactions well worked out but also it is possible to generate the carbene from several sources. This is important because comparisons of properties of the intermediate formed from several sources allow identification of the common reaction species as the carbene. Thus in this case, but not all others, reactive nitrogen-containing intermediates derived from phenyldiazomethane can be eliminated. ${ }^{4}$ We wondered if the stability conferred by a phenyl group upon an adjacent divalent carbon would be duplicated by a carborane. Would the effect of "two-dimensional" aromaticity be resembled by those of the "three-dimensional" or "super aromaticity" of the carboranes? In considering the possibilities we must examine steric, inductive, and resonance effects. ${ }^{5}$

The term "superaromatic" has been justified by a variety of MO treatments. ${ }^{5.6}$ A system of 13 bonding MO's is nicely filled by the 26 electrons ( 6 from the two carbons, 20 from the 10 borons) involved in framework bonding. The predicted stability finds support in the ease of substitution reactions ${ }^{5,7}$ and of course in the renowned stability of the icosahedral frame which routinely survives $400^{\circ} \mathrm{C}$, suffering at higher temperatures only rearrangement from the ortho isomer to the meta (ca. $500^{\circ} \mathrm{C}$, quantitative in a flowing system at $600^{\circ} \mathrm{C}$ ) followed by a less clean conversion to para ( $50 \%$ at $>600^{\circ} \mathrm{C}$ ). ${ }^{5,8}$ However, it is not clear that this thermodynamic stability is accompanied by stabilizing effects on attached positions, as clearly is the case in benzene and its derivatives. A study of arylcarboranes showed that although the two icosahedrons, and especially the ortho isomer, were highly electron withdrawing inductively, there was no substantial ground state "extension of electron delocalization by interaction with the aryl group". Similarly, there is no strong case to be made that the analogue of naphthalene, in which one benzene ring is replaced by a carborane, ${ }^{10}$ is more than a diene appended to the icosahedron. Only the NMR spectrum provides tenuous evidence of aromatic behavior. Even here the chemical shift of the diene protons is only $0.2-0.3 \mathrm{ppm}$ downfield from that

[^4]expected of a diene. ${ }^{11}$ Of direct impact on our projected work was the finding of Hutton and Roth of the Bell Laboratories group, along with one of us, that EPR spectra of 0 -carboranylcarbene and a C-methylated derivative showed little delocalization of $\pi$-spin density. ${ }^{12}$

On first thought it might be expected that there would be enormous steric differences between the flat, six-atom frame benzene ring and the 12 -atom frame, three-dimensional icosahedral carboranes. Not so. The $2.8-\AA$ para $\mathrm{C}-\mathrm{C}$ bond distance in benzene is increased by only a few tenths of $1 \AA$ in the various "para" distances in $o-, m$-, and $p$-carboranes. ${ }^{6}$ The size difference is not so great as one might imagine. Carboranes are the size of slightly elongated, rotating benzene rings. One possible indication that size differences will be of minor import is the observation that in the interaction of $o$-carboranyl alanine with chymotrypsin, the carboranyl group could bind with the "phenyl recognition site". ${ }^{13}$
(1) $o$-Carborane and $m$-carborane are 1,2-dicarba-closo-dodecaborane (12) and 1,7-dicarba-closo-dodecaborane (12), respectively.
