Potentials of tungsten-containing clusters are 0.20 V more negative than those of their molybdenum analogues. This property, together with the lability of coordinated solvent molecules, leads to the possibility that reduced clusters in the presence of a protic source may be able to bind and effect reductive transformations of nitrogenase substrates. This matter and other structural, electronic, and reactivity features of individual MFe₃S₄-type clusters are under investigation.

The Hydrogen Oxide Bridging Ligand (H_3O_2) . 1. Dimerization and Polymerization of Hydrolyzed Trinuclear Metal Cluster Ions

Avi Bino* and Dan Gibson

Contribution from the Department of Inorganic and Analytical Chemistry, The Hebrew University of Jerusalem, 91904 Jerusalem, Israel. Received December 2, 1981

Abstract: Trinuclear metal cluster ions of molybdenum and tungsten undergo hydrolysis in aqueous solutions. By the addition of various counterions such as Cl⁻, Br⁻, I⁻, and NCS⁻ to this solution several hydrolysis products with different degrees of polymerization have been crystallized. The preparation and X-ray structural characterization of six new compounds are reported; full structural details are presented for two compounds. The two compounds are isomorphous having the formula $\{[M_3O_2, M_3O_2, M_3O_2, M_3O_2, M_3O_2, M_3O_3, M_3O$ $(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)$ Br 6H₂O, in compound 1, M = Mo, and in 2, M = W. They crystallized in space group $P\overline{1}$ with the following cell dimensions: 1, a = 14.358 (4) Å, b = 12.114 (3) Å, c = 11.402 (2) Å, $\alpha = 111.08$ (2)°, $\beta = 105.69$ (3)°, $\gamma = 66.74$ (2)°, V = 1680 (2) Å³, and Z = 1; **2**, a = 14.316 (3) Å, b = 12.115 (2) Å, c = 11.423 (2) Å, $\alpha = 111.14$ (2)°, $\beta = 105.59$ (2)°, $\gamma = 66.59$ (2)°, V = 1677 (2) Å³, and Z = 1. Dimerization and polymerization occur by formation of a hydrogen oxide ligand (H₃O₂⁻), bridging between two metal atoms of adjacent cluster ions. The H₃O₂⁻ unit appearing in structures 1 and 2 is symmetric with an O-O separation of 2.52 (1) Å and 2.50 (1) Å, respectively.

 $M(OH)^{(n-1)+}$, the primary product of hydrolysis of a metal aquo ion $M(OH_2)^{n+}$, often undergoes condensation reactions to form hydrolytic dimers and polymers.¹ It is generally assumed that the metal atoms in these dimers and polymers are bridged by μ -hydroxo or μ -oxo ligands.^{2,3} These bridges are formed by elimination of a water molecule from a pair of ions (eq 1 and 2).

$$M(OH)^{(n-1)+} + (H_2O)M^{n+} \rightarrow (M-O-M)^{(2n-1)+} + H_2O$$
(1)

$$M(OH)^{(n-1)+} + (HO)M^{(n-1)+} \rightarrow (M-O-M)^{(2n-2)+} + H_2O$$
 (2)

This work reveals the existence of a different kind of bridging by means of a new ligand, the μ -hydrogen oxide ligand, H₃O₂⁻. Bridging by this ligand may be accomplished by formation of a strong hydrogen bond between the hydroxo ligand of one metal ion and the water ligand of the other ion. Formation of this $H_3O_2^{-1}$ bridge does not require the elimination of a water molecule (eq 3).

⁽¹⁾ Burgess, J. "Metal Ions in Solution"; E. Horwood: Chichester, 1978; pp 290-305.

Recent work on trinuclear clusters of the early transition elements in aqueous solution showed the existence of triangular species with a new type of structure, namely, M_3X_{17} shown in Figure 1.4-6 Molybdenum, tungsten, and niobium form a variety of M_3X_{17} triangular clusters all of which have the general formula $[M_3(\mu_3-X)_2(\mu-B)_6(H_2O)_3]^{n\pm} (X = O, CCH_3; B = O_2CR, SO_4).$ Clusters of group 6 metals are obtained by reaction of the hexacarbonyls with carboxylic acids.^{4,5} The niobium cluster is obtained by the reduction of Nb(V) in sulfuric acid.⁶

Almost all of the reports on the M_3X_{17} clusters dealt with two major aspects: (a) the preparation and (b) the structural characterization of these species.

The present work is part of a project exploring the chemistry of the M_3X_{17} metal clusters in aqueous solution including the substitution and electron-transfer reactions.

In a preliminary communication we reported the discovery of the complex ion $\{[M_3O_2(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)\}^{3+}$ (M = Mo,

Figure 1. A general representation of the M_3X_{17} structure.

W) in which two triangular metal clusters are bridged by a μ -H₃O₂ ligand.⁷ This bridging ligand may play an important role, not only in the solid-state and solution chemistry of metal clusters but also in the hydrolysis of many other metal ions, such as simple aquo ions in solution.

With the purpose of determining the factors governing the occurrence of the $H_3O_2^-$ moiety in the solid state and the relationship with species in aqueous solution, we have synthesized a series of new compounds, all of which contain one or more bridging $H_3O_2^-$ ligands.

In a series of papers, these compounds will be described in detail. In the first paper we report the preparation and structure of six compounds, two of which will be described in detail. Structural results on the bridging $H_3O_2^-$ unit are presented here for the first time.

Experimental Section

Preparation of { $[Mo_3O_2(O_2CC_2H_3)_6(H_2O)_2]_2(H_3O_2)$ }**Br**₃·**6H**₂**O** (1). Mo(CO)₆ (1 g) was refluxed overnight with 100 mL of a 1:2 mixture of propionic acid and propionic anhydride. The resulting dark brown solution was diluted with 200 mL of H₂O and stirred on a hot plate at 70 °C for over 1 h. The solution was filtered and absorbed on a cationexchange column (Dowex 50W-X2). The column was washed with a solution of KBr (0.2 M). The red band, remaining on the column, was eluted with 0.5 M KBr. Red crystals were obtained by slow evaporation of the eluate.

Preparation of $\{[W_3O_2(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)\}Br_3\cdot6H_2O$ (2). This compound was prepared in a way analogous to the Mo complex (1) using $W(CO)_6$. Anal. Calcd for $W_6Br_3O_{40}C_{36}H_{83}$: W, 44.16; Br, 9.60; C, 17.30; H, 3.32. Found: W, 44.4; Br, 9.85; C, 17.44; H, 3.13.

Preparation of $\{[Mo_3O_2(O_2CC_2H_3)_6(H_2O)_2]_2(H_3O_2)\}I_3.6H_2O$ (3) and $\{[W_3O_2(O_2CC_2H_3)_6(H_2O)_2]_2(H_3O_2)\}I_3.6H_2O$ (4). These compounds were prepared in the same way as 1 and 2, respectively, but the elution from the column was carried out with 0.5 M KI.

Preparation of [W_3O_2(O_2CC_2H_3)_6(H_2O)(H_3O_2)]NCS (5).A 100-mg sample of**2** $was dissolved in <math>H_2O$ (15 mL). KNCS (0.75 g) was added, and the solution was placed in an open beaker. After a few hours, deep yellow-brown crystals were deposited.

Preparation of $[W_3O_2(O_2CC_2H_3)_6(H_2O)_3]Cl_2H_2O$ (6). The same procedure as for 2. The yellow ion was eluted with 0.5 M KCl. The aqueous solution of 6 is strongly acidic. The pH of a solution of 4 mM is approximately 3.0.

Alternative Preparation of 2, 4, and 5. Compound 6 may be used as a starting material for the synthesis of these compounds. An excess of the appropriate salt KX (X = Br, I, NCS) is added to a concentrated aqueous solution of 6. The respective compounds precipitate upon evaporation of the solution.

 \bar{X} -ray Crystallography. Data were collected for compounds 1 and 2 on a PW 1100 Philips four-circle computer-controlled diffractometer. Mo K α ($\lambda = 0.71069$ Å) radiation with a graphite crystal monochromator in the incident beam was used. The unit-cell dimensions were obtained by a least-squares fit of 25 reflections in the range $12^{\circ} < \theta <$ 16°. Data were measured by using a ω -2 θ motion. The scan width, $\Delta\omega$, for each reflection was 1° with scan time of 20 s. background mea-

^{*a*} 1, $[Mo_3O_2(O_2CC_2H_5)_6(H_2O)_2-(H_3O_2)-Mo_3O_2(O_2CC_2H_5)_6-(H_2O)_2]Br_3 \cdot 6H_2O$. ^{*b*} 2, $[W_3O_2(O_2CC_2H_5)_6(H_2O)_2-H_3O_2-W_3O_2-(O_2CC_2H_5)_6(H_2O)_2]Br_3 \cdot 6H_2O$.

Figure 2. The labeling scheme of structures 1 and 2. For the sake of clarity all atoms were given an arbitrary isotropic thermal parameters of $U_{11} = 0.02$ Å². OW₃ is the oxygen atom of the H₃O₂⁻-bridging ligand.

surements were made at both limits of each scan. Crystallographic data and other pertinent information are given in Table I. For each crystal, Lorentz and polarization corrections were applied. Intensity data for 1 and 2 were corrected for absorption by the empirical ψ -scan method. The heavy-atom positions in 1 were obtained from a three-dimensional Patterson function, and the structure was refined⁸ in space group P1 to convergence. All propionato hydrogen atoms and coordinated water hydrogen atoms including the two of the H₃O₂⁻ ligand were located from the difference Fourier map. The 30 propionato hydrogen atoms were introduced at calculated positions (which were found to correspond to those found from the difference map), and the six coordinated water hydrogen atoms were introduced in the positions obtained from the difference Fourier map. Only those two in the H₃O₂⁻ unit, H(1) and H(2), were refined; the other 34 hydrogen atoms in the structure were introduced as fixed contributions to F.

Anisotropic thermal parameters were used for all molybdenum, bromine, and oxygen atoms and isotropic ones for the carbon atoms and for H(1) and H(2). The positions of all non-hydrogen atoms of 2 were taken from 1. Anisotropic thermal parameters were used for all tungsten, bromine, and oxygen atoms and isotropic ones for all carbon atoms.

The discrepancy indices, $R_1 = \sum ||F_0| - |F_c|| / \sum |F_0|$ and $R_2 = [\sum w(|F_0| - |F_c|)^2 / \sum w|F_0|^2|^{1/2}$, are listed in Table I. The final difference map in both structures showed no peaks of structural significance. Lists of all observed and calculated structure factors are available as supplementary material. Details of data collection, solution, and refinement of the structures of 3-6 will appear elsewhere.

⁽⁸⁾ All crystallographic computing was done on a CYBER 74 computer at the Hebrew University of Jerusalem, using the SHELX 1977 structure determination package.

Figure 3. A stereoview of the unit cell of $\{[M_3O_2(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)\}Br_3 \cdot 6H_2O$

Results

Compound 1. $\{[Mo_3O_2(O_2CC_2H_3)_6(H_2O)_2]_2(H_3O_2)\}Br_3\cdot 6H_2O$. The atomic positional parameters are listed in Table II while Table III gives the important bond lengths and angles. The thermal parameters and the calculated positional parameters of the propionato and coordinated water hydrogen atoms are listed in a table included in the supplementary material. Figure 2 shows the numbering scheme in 1 and 2 while Figure 3 gives a stereoview of the contents of the entire unit cell.

With Z = 1 in the space group $P\bar{1}$ there is only half a $\{[Mo_3O_2(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)\}^{3+}$ ion in the asymmetric unit, with the other half related to it by a crystallographic inversion center at 0, 0, 0. There are three bromide anions in the cell two of which occupy general positions and one resides on a crystallographic inversion center at 1/2, 1/2. The hydrogen oxide ion and its dimensions are shown in Figure

The hydrogen oxide ion and its dimensions are shown in Figure 4. Both H(1) and H(2) were located from the difference Fourier map; H(1) was found on the crystallographic inversion center at 0, 0, 0. The thermal parameters of H(1) and H(2) and the positional parameters of H(2) were included in the least-squares refinement. The isotropic thermal vibration parameter, U_{11} , of H(1) and H(2) were refined to the reasonable values of 0.10 (6) and 0.06 (4) Å², respectively. The value of 0.7 (1) Å for the OW(3)-H(2) distance is acceptable for such a structural study using X-ray data.⁹ More accurate values for the dimensions of

Figure 4. The structure and dimensions of the Mo-O(H)HO(H)-Mo portion in 1. Only Mo-O bonds are depicted in the coordination sphere of the metal atoms. H(1) and H(2) were given an arbitrary isotropic thermal parameters of $U_{11} = 0.02$ Å² for the sake of clarity.

the $H_3O_2^-$ unit may be obtained by neutron diffraction, and we are attempting to grow suitable crystals of 1 for such a study. Compound 2. { $[W_3O_2(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)$ }Br₃·6H₂O. This compound and 1 are isostructural. The atomic positional

parameters are listed in Table IV. Tables of thermal parameters and bond lengths and angles are included in the supplementary material.

Compounds 3 and 4. { $[M_3O_2(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)$ }I₃. 6H₂O (M = Mo, W). These two compounds form isomorphous crystals. They crystallize in the triclinic space group PI with Z = 2. The asymmetric unit contains an entire { $[M_3O_2-(O_2CC_2H_5)_6(H_2O)_2]_2(H_3O_2)$ }³⁺ ion; hence there is no crystallographic symmetry imposed on this ion as in 1 or 2. There are six iodide anions in the cell. The geometry and dimensions of the 3+ cation in 3 (M = Mo) and 4 (M = W) are essentially identical with those found in 1 and 2, respectively. The detailed structural information of 3 and 4 will be presented elsewhere.

Compound 5. $[W_3O_2(O_2CC_2H_5)_6(H_2O)(H_3O_2)]NCS.$ In this compound, each triangular W_3 cluster is bridged by *two* $H_3O_2^-$ ligands to two adjacent clusters forming an infinite chain in the lattice. The asymmetric unit of space group $P2_1/c$ contains one $[W_3O_2(O_2CC_2H_5)_6(H_2O)(H_3O_2)]^+$ ion and one NCS⁻ anion. The detailed structure will be presented elsewhere.

Compound 6. $[W_3O_2(O_2CC_2H_5)_6(H_2O)_3]Cl_2 H_2O$. The $[W_3O_2(O_2CC_2H_5)_6(H_2O)_3]^{2+}$ unit is essentially identical with that found in the fluoroborate salt $[W_3O_2(O_2CC_2H_5)_6(H_2O)_3]$ - $(BF_4)_2 \cdot 5.5H_2O.^{5a}$ The 2+ charge is balanced by two chloride anions in the lattice. The detailed structure will be presented elsewhere.

Discussion

The existence of the hydrogen oxide anion, $H_3O_2^-$, has been postulated for a long time¹⁰ but only recently has the first structural characterization of this species been accomplished.¹¹ The compound $Na_2[(C_2H_5)_3(CH_3)N][Cr(PhC(S)=N(O))_3]$. $^1/_2NaH_3O_2$ ·18H₂O, described by Raymond et al., has been crystallized from an alkaline solution and is the first example of a crystalline substance containing the "hydrated hydroxide", $H_3O_2^-$, ion as a *discrete entity* in a crystal lattice. This species is the primary hydration product of OH⁻ with a symmetric O· ··H···O bond and O-O separation of 2.29 Å. The central $H_3O_2^$ ion is surrounded by four additional water molecules, each forming a hydrogen bond to a lone pair on one of the oxygen atoms of the $H_3O_2^-$ ion.

In the present work we describe a series of compounds that contain a hydrogen oxide *bridging ligand* between two metal atoms. These compounds have been crystallized from acidic solutions.

The bridging $H_3O_2^-$ unit in compounds 1 (Figure 4) and 2 is symmetric just as the discrete unit in Raymond's compound. In all three cases it resides on a crystallographic inversion center, and in 1 the central hydrogen atom is located on the inversion center. The structural differences between the $H_3O_2^-$ unit in Raymond's compound and those found in our series are the following (a) the four electron pairs on each of the $H_3O_2^-$ oxygen atoms in the free ion are engaged in bonds to hydrogen atoms (two covalent O-H bonds and two long-range hydrogen bonds) while in the bridging $H_3O_2^-$ ligands only three electron pairs are utilized as can be seen in Figure 4. (b) The O-O separation in the coordinated unit is significantly longer (2.52 Å in 1 and 2.50 Å in 2) than the 2.29 Å reported by Raymond.¹¹ These differences are due to the fact that the oxygen atoms of the $H_3O_2^-$ ligand are coordinated to the metal atoms, donating a pair of electrons to the metal orbitals and hence becoming more positively charged.

The replacement of one water ligand in the M_3 cluster by an $H_3O_2^-$ ligand causes a considerable distortion of the equilateral triangle of metal atoms. Table V shows the M-M bond distances in compounds 1 and 2 as compared with 6 and those found in $[W_3O_2(O_2CC_2H_5)_6(H_2O)_3](BF_4)_2^{5a}$ and $[Mo_3O_2(O_2CC_2H_5)_6(H_2O)_3](BF_4)_2^{5a}$

^a Numbers in parentheses are esd's occurring in the last significant figure. Crystallographically distinct but chemically equivalent distances have been averaged.

 $(H_2O)_3](CF_3SO_3)_2$.^{4e} This distortion leads to an isosceles triangle by displacement of the bridged metal atom, M(3), toward the $H_3O_2^-$ unit. As a results, the M(3)-M distance [M = M(1) or M(2)] increases by ca. 0.02 Å in 1 and in 2. The M(3)-O(H_3O_2^-) distance decreases by ca. 0.1 Å (compared to the average M-O-(H_2O) distance of 2.11 Å) to ca. 2.00 Å. A similar decrease of the M-O distance was observed when other negatively charged ligands such as an acetate ion replaced a water molecule coordinated to a W(IV) atom in a similar triangular cluster.^{5a}

The coordinated water ligand in the cluster $[M_3O_2-(O_2CC_2H_5)_6(H_2O)_3]^{2+}$ dissociates and produces acidic solution as in eq 4 (the μ_3 -O and propionato ligands were omitted). In

this respect, the coordinated water ligand in the metal cluster resembles a water ligand in a mononuclear metal aquo cation. The extent of hydrolysis is mainly the function of the ratio of ionic charge to ionic radius of the metal ion. In the trinuclear clusters described here, the molybdenum and the tungsten atoms are in the +4 oxidation state with a relatively small ionic radius. As a result, the acidity of the coordinated water ligands of the cluster is high, a fact demonstrated by the very low pH of the aqueous solutions of the "aquo complex" (compound 6).¹²

In the following discussion we shall refer to the 2+ ion, appearing in compound 6 (with three water ligands in the coordination sphere of the W₃ triangle), $[W_3O_2(O_2CC_2H_5)_6(H_2O)_3]^{2+1}$

as the monocluster. The 3+ cation, $\{[W_3O_2(O_2CC_2H_5)_6-(H_2O)_2]_2(H_3O_2)\}^{3+}$, with the two W_3 clusters bridged by $H_3O_2^{-1}$ unit will be designated *dicluster* (see eq 5) and the infinite chain of W_3 clusters bridged by $H_3O_2^{-1}$ ligands in 5 will be named polycluster (see eq 4).

The fact that from an aqueous solution of the monocluster, salts of the dicluster and the polycluster are precipitated by the use of different counterions (Br⁻, I⁻, NCS⁻) supports the assumption that the *di*- and *polycluster* ions exist in the *aqueous* solution in equilibrium with species I (eq 5 and 6). Presumably the difference in solubilities of the salts of the mono-, di-, and polycluster determines which salt will be precipitated from solution. While crystallization of the monocluster occurs only with Cl⁻, the dicluster crystallizes with Br or I and the polycluster only with NCS⁻. Apparently the chloride is the least soluble of the monocluster salts and therefore precipitates in preference to the dicluster or polycluster chlorides. On the other hand, the higher solubilities of the monocluster bromide and iodide prevent the precipitation before the solubility product of the respective dicluster salts is attained. The precipitation of the dicluster bromide or iodide shifts the equilibrium in the aqueous solution in their favor and ensures continued precipitation of these salts. Similar reasoning applies to the precipitation of the polycluster thiocyanate salt (5). The difference in solubilities of the mono- and dicluster salts is probably due to the different contribution of the counterion X⁻ and the bridging ligand $H_3O_2^-$ to the lattice energies of the respective salts. In a monocluster salt we have two X⁻ ions per cluster unit where as in the *dicluster* salt we have one and half X⁻ ions and half $H_3O_2^-$ ligand (three X⁻ and one $H_3O_2^-$ per two clusters as in 1-4). The small chloride ion contributes more to the lattice energy than the bigger bromide and iodide. It is surrounded by a network of short hydrogen bonds to water molecules and water ligands in the lattice of 6. The larger Brand I⁻, with smaller effective charge, contribute less energy than Cl⁻ by hydrogen bonding to water molecules. Thus, the structure

⁽¹²⁾ See Experimental Section preparation of 6.

of a *dicluster* consisting of one $H_3O_2^-$ and three X⁻ anions becomes more favorable with Br⁻ and I⁻ than with Cl^{-,13} The NCS⁻ ion is even larger than Br⁻ or I⁻ and the energy gained by hydrogen bonding of this ion in the lattice is even smaller. Therefore the solubilities of both the *mono-* and the *dicluster* thiocyanates are large enough to enable the precipitation of the *polycluster* ion

present in solution by NCS⁻. In this salt (5) the 2+ charge of the W_3 cluster is balanced by one NCS⁻ and one (two halves) $H_3O_2^{-}$ ligand.

Is the existence of $H_3O_2^{-}$ -bridged "dimers" and "polymers" in equilibrium with hydrolized "monomers" in solution a phenomenon limited only to trinuclear metal clusters?

As we mentioned before, no substantial differences exist between a water ligand in a metal cluster coordination and a water ligand bound to a mononuclear metal ion (such as Fe³⁺ or Al³⁺). Therefore it is quite possible that the existence of $H_3O_2^{-}$ -bridged polymer ions is a general phenomenon in aqueous solutions of many metal ions. The fact that other salts containing the hydrogen oxide bridging ligand have not been crystallized before may be due to their high solubility. Even in systems containing species such as $[M_3(\mu_3-O)_2(\mu-L)_6(H_2O)_3]^{2+}$, $H_3O_2^{-}$ -bridged clusters crystallized only with $L = O_2CC_2H_5$ and not with smaller L μ_2 -ligands such as acetates.^{4e}

All the dimeric and polymeric hydrolysis products of metal ions that are believed to be bridged by μ -hydroxo or μ -oxo bridges are formed in reactions much slower than the reaction forming the mononuclear hydroxo species $M(OH)^{(n-1)+}$. If polymeric species with $H_3O_2^-$ bridges, as suggested in this work, do exist in aqueous solution, they are probably formed from the mononuclear species by an "instantaneous" (diffusion-controlled) reaction because their formation requires only a hydrogen bond formation and does not involve any metal-ligand bond breaking. In contrast to this very rapid reaction, the rate of formation of dimers and polymers bridged by μ -OH or μ -O ligands is slower by many orders of magnitude since these reactions require breaking of M-L bonds.¹⁴

Another important difference between the μ -H₃O₂⁻-bridged polymers and the μ -OH or μ -O species is the metal to metal separation. μ -H₃O₂⁻ bridging is characterized by an M-M separation of ca. 5.6 Å. This is much longer than in any μ -OH or μ -O complex.¹ Investigating the existence of μ -hydrogen oxide bridged polymers in aqueous solutions of ordinary metal ions is not an easy task. We intend to employ suitable techniques such as EXAFS and X-ray scattering experiments to this end.

⁽¹³⁾ The BF₄⁻ and the CF₃SO₃⁻ salts of $[M_3O_2(O_2CC_2H_5)_6(H_2O)_3]^{2+}$ crystallize as monoclusters ^{5a 4e} due to the extensive network of strong hydrogen bonds surrounding these anions.

⁽¹⁴⁾ For example, the first-order rate constant of the reaction $Fe_2(OH)_2^{4+}$ \Rightarrow Fe(OH)²⁺ was estimated to be 0.4 s⁻¹ (ref 3, p 234).
