## Department of Chemistry <br> Massachusetts Institute of Technology Cambridge, Massachusetts 02139 <br> and Department of Chemistry State University of New York Buffalo, New York 14214 <br> Received July 29, 1982

We have reported that $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{O}-t-\mathrm{Bu})_{3}$ will catalytically metathesize dialkylacetylenes at a high rate, presumably by forming unstable tungstenacyclobutadiene intermediates. ${ }^{2}$ On the other hand, while complexes such as $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})\left(\mathrm{CH}_{2}-t-\mathrm{Bu}\right)_{3}{ }^{3}{ }^{3}$ $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{dme}) \mathrm{Cl}_{3},{ }^{4}$ and $\left[\mathrm{NEt}_{4}\right]\left[\mathrm{W}(\mathrm{C}-t-\mathrm{Bu}) \mathrm{Cl}_{4}\right]^{2}$ will react with acetylenes, they do not metathesize them catalytically. We report here that $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{dme}) \mathrm{Cl}_{3}$ reacts with dialkylacetylenes to give a stable tungstenacyclobutadiene complex, that tungstenacyclobutadiene complexes containing certain alkoxide ligands (but not three tert-butoxide ligands) are also stable, and that cyclopentadienyl complexes are formed in the presence of excess dialkylacetylene, even (slowly) in the active alkyne metathesis system.

Excess 3-hexyne reacts with $\left[\mathrm{NEt}_{4}\right]\left[\mathrm{W}(\mathrm{C}-t-\mathrm{Bu}) \mathrm{Cl}_{4}\right]$ in dichloromethane to give a pentane-soluble paramagnetic red complex with the empirical formula $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{C} \equiv\right.$ $\left.\mathrm{CCH}_{2} \mathrm{CH}_{3}\right)_{3} \mathrm{Cl}_{2}$ in $\sim 50 \%$ yield. 2-Butyne reacts more rapidly with $\left[\mathrm{NEt}_{4}\right]\left[\mathrm{W}(\mathrm{C}-t-\mathrm{Bu}) \mathrm{Cl}_{4}\right]$ to give an analogous ether-soluble species. Both can be obtained more straightforwardly by reacting an excess of the alkyne with $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{dme}) \mathrm{Cl}_{3}{ }^{4}{ }^{4}$ In this reaction a less soluble, paramagnetic, orange complex with the empirical formula $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})$ (alkyne) ${ }_{2} \mathrm{Cl}_{4}{ }^{5}$ also forms in $\sim 50 \%$ yield by weight. A molecular weight study of "W(C-t-Bu)(EtC $\equiv$ $\mathrm{CEt})_{2} \mathrm{Cl}_{4}{ }^{\text {" }}$ in dichloromethane at $0^{\circ} \mathrm{C}$ (by differential vapor pressure measurement) showed it to be a dimer.

An X-ray structural study ${ }^{6}$ of $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{MeC} \equiv \mathrm{CMe})_{3} \mathrm{Cl}_{2}$ " shows it to be $\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{4}-t-\mathrm{Bu}\right)(\mathrm{MeC} \equiv \mathrm{CMe}) \mathrm{Cl}_{2}$, a species that is closely related to the diamagnetic Ta (III) derivatives, $\mathrm{Ta}-$ $\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{5}\right)$ (alkyne) $\mathrm{Cl}_{2}{ }^{7}$ As in $\mathrm{Ta}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{5}\right)(\mathrm{PhC} \equiv \mathrm{CPh}) \mathrm{Cl}_{2}$, ${ }^{7}$

Figure 1. ORTEP-11 diagram ( $30 \%$ ellipsoids) of $\mathrm{W}[\mathrm{C}-t-\mathrm{BuCMeCMe}] \mathrm{Cl}_{3}$ with hydrogen atoms omitted.
Scheme 1
$W(C E t)\left(\mathrm{OBu}^{\dagger}\right)_{3}+E t C E C E \dagger \rightarrow$ red

the axis of the acetylene ligand in $\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{4}-t-\mathrm{Bu}\right)(\mathrm{MeC} \equiv$ $\mathrm{CMe}) \mathrm{Cl}_{2}$ lies parallel to the plane of the cyclopentadienyl ligand, and the acetylene carbon-carbon bond length is lengthened considerably as a result of its strong bond to the metal. Therefore, we propose that the " $\left[\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\text { alkyne })_{2} \mathrm{Cl}_{4}\right]_{2}$ " species are also substituted cyclopentadienyl complexes, $\left[\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\mathrm{Bu}\right) \mathrm{Cl}_{4}\right]_{2}$. Most likely $\mathrm{W}\left(\eta^{3}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\mathrm{Bu}\right)(\mathrm{RC} \equiv \mathrm{CR}) \mathrm{Cl}_{2}$ and $\left[\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\right.\right.$ $\left.\mathrm{Bu}) \mathrm{Cl}_{4}\right]_{2}$ form via disproportionation of some intermediate tungsten(IV) complex, possibly " $\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\mathrm{Bu}\right) \mathrm{Cl}_{3}{ }^{\text {" }}$ as shown in eq 1 and 2.
$\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{dme}) \mathrm{Cl}_{3}+2 \mathrm{RC} \equiv \mathrm{CR} \rightarrow " \mathrm{~W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\mathrm{Bu}\right) \mathrm{Cl}_{3}{ }^{"}$

$$
\begin{align*}
& " \mathrm{~W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\mathrm{Bu}\right) \mathrm{Cl}_{3}{ }^{n} \xrightarrow{0.5 \mathrm{RC} \equiv \mathrm{CR}}  \tag{1}\\
& \quad 0.5 \mathrm{~W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\mathrm{Bu}\right)\left(\mathrm{RC} \equiv \mathrm{CR}^{2}\right) \mathrm{Cl}_{2}+ \\
& \quad 0.25\left[\mathrm{~W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{R}_{4}-t-\mathrm{Bu}\right) \mathrm{Cl}_{4}\right]_{2} \tag{2}
\end{align*}
$$

Addition of only 1 equiv of 3 -hexyne or 2 -butyne to W (C-t$\mathrm{Bu})(\mathrm{dme}) \mathrm{Cl}_{3}$ yields violet diamagnetic complexes with the formula $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{RC} \equiv \mathrm{CR}) \mathrm{Cl}_{3} .^{8} \quad{ }^{13} \mathrm{C}$ NMR studies suggested that these species are tungstenacyclobutadiene complexes. ${ }^{9}$ An X-ray structural study ${ }^{10}$ of $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})\left(\mathrm{MeC} \equiv \mathrm{CMe}^{2}\right) \mathrm{Cl}_{3}$ confirmed this proposal (Figure 1). The molecule is nearly a trigonal bipyramid with axial chloride ligands $\left(\angle \mathrm{Cl}(1)-\mathrm{W}-\mathrm{Cl}(2)=166.12(9)^{\circ}\right)$ and

[^0]an essentially planar $\mathrm{WC}_{3}$ ring lying in the equatorial plane. The substituent carbon atoms ( $\mathrm{C}(2), \mathrm{C}(8), \mathrm{C}(9))$ and $\mathrm{Cl}(3)$ also lie in the equatorial plane. The $\mathrm{W}-\mathrm{C}_{\alpha}$ bond lengths are equal and slightly shorter than the $\mathrm{W}=\mathrm{C}_{\alpha}$ double bond distance of 1.942 (9) $\AA$ found in $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{CH}-t-\mathrm{Bu})\left(\mathrm{CH}_{2}-t-\mathrm{Bu}\right)(\mathrm{dmpe}) .{ }^{12}$ Carbon-carbon distances within the four-membered ring are intermediate between those expected for pure double and pure single bonds but are slightly closer to the latter. The three most surprising features are the large $\mathrm{C}_{\alpha}-\mathrm{C}_{\beta}-\mathrm{C}_{\alpha}$ angle (118.9 (8) ${ }^{\circ}$ ), the short $\mathrm{W}-\mathrm{C}_{\beta}$ distance (far shorter than the $\mathrm{W}-\mathrm{C}_{\alpha}$ single bond length of 2.258 (8) $\AA$ in $\mathrm{W}(\mathrm{C}-t-\mathrm{Bu})(\mathrm{CH}-t-\mathrm{Bu})\left(\mathrm{CH}_{2}-t-\mathrm{Bu}\right)$ (dmpe) ${ }^{12}$ ), and the large $W-C(1)-C(2)$ and $W-C(7)-C(8)$ angles ( 149.9 (7) and $156.6(7)^{\circ}$, respectively). These results contrast sharply with those for $\mathrm{Rh}\left(\mathrm{C}_{3} \mathrm{Ph}_{3}\right) \mathrm{Cl}_{2}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{2}{ }^{13}$ and [ Ir $\left.\left(\mathrm{C}_{3} \mathrm{Ph}_{3}\right)(\mathrm{CO})(\mathrm{Cl})\left(\mathrm{PMe}_{3}\right)_{2}\right]^{+14}$ in which little, if any, multiple metal-carbon bond character is present, and the metallacyclic unit is compressed along the $\mathrm{C}_{\alpha}-\mathrm{C}_{\alpha^{\prime}}$ direction. (The $\mathrm{C}_{\alpha}-\mathrm{C}_{\alpha^{\prime}}$ distance in $\mathrm{W}[\mathrm{C}-t$ - BuCMeCMe$] \mathrm{Cl}_{3}$ is 2.525 (12) $\AA$ but in $\mathrm{RhCl}_{2}-$ $\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{2}\left(\mathrm{C}_{3} \mathrm{Ph}_{3}\right)^{13}$ it is only 2.156 (6) $\AA$.)
$\mathrm{W}[\mathrm{C}-t-\mathrm{BuCMeCMe}] \mathrm{Cl}_{3}$ reacts with 1 equiv of tert-Butyl alcohol in the presence of $\mathrm{NEt}_{3}$ to give W[C- $t$-BuCMeCMe](O-(t-%5Cmathrm%7BBu%7D) \mathrm{Cl}_{2}{ }^{15}\) Addition of a second equivalent of $\mathrm{LiO}-t-\mathrm{Bu}$ to $\mathrm{W}[\mathrm{C}-t-\mathrm{BuCMeCMe}](\mathrm{O}-t-\mathrm{Bu}) \mathrm{Cl}_{2}$ produces only half an equivalent of $\mathrm{W}(\mathrm{CR})(\mathrm{O}-t-\mathrm{Bu})_{3}$ where R is $t$ - Bu or Me. Surprisingly, therefore, $\mathrm{W}[\mathrm{C}-t$ - BuCMeCMe$](\mathrm{O}-t-\mathrm{Bu})\left(\mathrm{OCMe}_{2} \mathrm{CMe}_{2} \mathrm{O}\right)$ can be prepared ${ }^{16}$ and is stable toward cleavage of the $\mathrm{WC}_{3}$ ring or formation of the $\beta$-tert-butyl-substituted isomer. Furthermore, addition of 1 equiv of pinacol to a mixture of $\mathrm{W}(\mathrm{CEt})(\mathrm{O}-t-\mathrm{Bu})_{3}$ and 3-hexyne yields an analogous complex, $\mathrm{W}\left(\mathrm{C}_{3} \mathrm{Et}_{3}\right)(\mathrm{O}-t$ $\mathrm{Bu})\left(\mathrm{OCMe}_{2} \mathrm{CMe}_{2} \mathrm{O}\right)^{17}$ (Scheme I). The pinacolate complexes will not metathesize 3-heptyne. At least one of the reasons is that $\mathrm{W}\left(\mathrm{C}_{3} \mathrm{Et}_{3}\right)(\mathrm{O}-t-\mathrm{Bu})\left(\mathrm{OCMe}_{2} \mathrm{CMe}_{2} \mathrm{O}\right)$ reacts with an excess of 3-hexyne to give colorless $\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Et}_{5}\right)(\mathrm{O}-t-\mathrm{Bu}) \mathrm{O}_{2}{ }^{18}$ and tetramethylethylene quantitatively, possibly via intermediate, unstable $\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Et}_{5}\right)\left(\mathrm{OCMe}_{2} \mathrm{CMe}_{2} \mathrm{O}\right)(\mathrm{O}-t$ - Bu$) .{ }^{19}$

The question that remained was why alkyne metathesis using $\mathrm{W}(\mathrm{CR})(\mathrm{O}-t-\mathrm{Bu})_{3}$ catalysts eventually ceases? We know that $\mathrm{W}_{2}(\mathrm{O}-t-\mathrm{Bu})_{6}$ cannot be formed since it reacts with dialkylacetylenes to give $\mathrm{W}(\mathrm{CR})(\mathrm{O}-t-\mathrm{Bu})_{3}{ }^{21}$ A simpler "active" system consisting of a mixture of $\mathrm{W}(\mathrm{CEt})(\mathrm{O}-t-\mathrm{Bu})_{3}$ and excess 3 -hexyne was allowed to "decompose" to give an as yet unidentified diamagnetic red complex with the empirical composition W-$(\mathrm{CEt})_{5}(\mathrm{O}-t-\mathrm{Bu})_{3}$ (by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C} \mathrm{NMR}$ ). This red species slowly (days) also decomposed to give colorless $\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Et}_{5}\right)(\mathrm{O}-t-\mathrm{Bu}) \mathrm{O}_{2}$, the only significant diamagnetic product.

We conclude from these results that tungstenacyclobutadiene complexes are the intermediates in the alkyne metathesis reaction and that they can react with additional alkyne to yield cyclopentadienyl complexes. We can also now expect that cleavage

[^1]of a tungstenacyclobutadiene ring or further reaction to give (ultimately) cyclopentadienyl complexes will likely prove to be very sensitive to the structure of the complex and (especially) the steric and electronic properties of the ligands.

## Protiodesilylation Reactions of Simple $\beta$-Hydroxysilanes (and $\alpha$-Hydroxysilanes). Homo-Brook Rearrangements ${ }^{1}$

Paul F. Hudrlik,* Anne M. Hudrlik, and Ashok K. Kulkarni
Department of Chemistry, Howard University Washington, DC 20059
Received July 1, 1982
$\beta$-Hydroxysilanes have been of considerable interest as precursors to geometrically defined olefins and heteroatom-substituted olefins because of their stereospecific olefin-forming $\beta$-elimination reactions, and therefore a number of methods to prepare diastereomerically pure $\beta$-hydroxysilanes have been developed. ${ }^{2}$ We have recently become interested in the possibility that the $\mathrm{R}_{3} \mathrm{Si}$ group in a $\beta$-hydroxysilane could be replaced by H (protiodesilylation) or by another substituent, thus enabling $\beta$-hydroxysilanes to serve as precursors to saturated organic systems. Here we report that simple unactivated $\beta$-hydroxysilanes can undergo protiodesilylation when treated with base in aqueous dimethyl sulfoxide ( $\mathrm{Me}_{2} \mathrm{SO}$ ), that unactivated $\alpha$-hydroxysilanes also undergo protiodesilylation (essentially a Brook rearrangement followed by hydrolysis) under these conditions, and that both reactions take place with complete retention of stereochemistry at carbon.

Cleavage of unactivated carbon-silicon bonds is ordinarily quite difficult. Our earlier work with $\alpha, \beta$-dihydroxysilanes ${ }^{3}$ suggested to us that base-induced protiodesilylation reactions should be facilitated by the presence of a $\beta$ hydroxyl as shown in the mechanistic rationale in Scheme I. Simple (unactivated) $\beta$-hydroxysilanes normally undergo facile $\beta$-elimination reactions when treated with base under aprotic conditions (e.g., KH/THF). (The reaction is considerably accelerated by the presence of anion-

Calcd for $\mathrm{WC}_{13} \mathrm{H}_{24} \mathrm{Cl}_{2} \mathrm{O}: \mathrm{C}$, 34.61; H, 5.36. Found, C, 34.56; H, 5.41. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right) \delta 3.08$ (s, 3, $\left.\mathrm{CMe}), 2.16(\mathrm{~s}, 3, \mathrm{CMe}), 1.75(\mathrm{~s}, 9, \mathrm{O}-t-\mathrm{Bu}), 1.39(\mathrm{~s}, 9, \mathrm{C}-t-\mathrm{Bu}) ;{ }^{13} \mathrm{C} \mid{ }^{1} \mathrm{H}\right\} \mathrm{NMR}$ $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right) \delta 265.6$ and $259.1\left(J_{\mathrm{CW}}=93,116 \mathrm{~Hz}, \mathrm{C}_{\alpha}\right), 134.2\left(\mathrm{C}_{8}\right), 87.9\left(\mathrm{OCMe}_{3}\right)$, $42.7\left(\mathrm{CCMe}_{3}\right), 31.1$ and $29.6\left(\mathrm{OCMe}_{3}\right.$ and $\left.\mathrm{CCMe} \mathrm{C}_{3}\right), 24.3$ and $12.4(\mathrm{CMe})$.
    (16) $\left.{ }^{13} \mathrm{C}^{[1} \mathrm{H}\right]$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right) \delta 232.1$ and $225.2\left(J_{\mathrm{CW}}=122,134 \mathrm{~Hz}, \mathrm{C}_{\alpha}\right)$, $128.9\left(\mathrm{C}_{8}\right), 88.3\left(\mathrm{O}_{2} \mathrm{C}_{2} \mathrm{Me}_{4}\right), 75.9\left(\mathrm{OCMe}_{3}\right), 40.4\left(\mathrm{CCMe}_{3}\right), 31.9,31.7$ and $27.6\left(\mathrm{OCMe}_{3}, \mathrm{CCMe} e_{3}\right.$ and $\mathrm{O}_{2} \mathrm{C}_{2} \mathrm{Me}_{4}$, not assignable), 22.0 and 13.0 (CMe). Molecular ion found at 496 in mass spectrum.
    (17) $\left.{ }^{13} \mathrm{C} \mid{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{C}_{6} \mathrm{D}_{6}\right) \delta 226.5\left(\mathrm{C}_{\alpha} \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 132.9\left(\mathrm{C}_{\beta} \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 75.6$ $\left(\mathrm{OCMe}_{3}\right), 31.8\left(\mathrm{OCMe}_{3}\right), 29.3\left(\mathrm{CCH}_{2} \mathrm{CH}_{3}\right), 27.6\left(\mathrm{O}_{2} \mathrm{C}_{2} \mathrm{Me}_{4}\right), 23.2\left(\mathrm{CCH}_{2}-\right.$ $\left.\mathrm{CH}_{3}\right), 16.0$ and $12.9\left(\mathrm{CCH}_{2} \mathrm{CH}_{3}\right)$. Molecular ion found at 496 in mass spectrum.
    (18) $\mathrm{W}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Et}_{5}\right)(\mathrm{O}-t-\mathrm{Bu}) \mathrm{O}_{2}$. Anal. Calcd for $\mathrm{WC}_{19} \mathrm{H}_{34} \mathrm{O}_{3}: \mathrm{C}, 46.17$; H, 6.93. Found: C, 45.78; H, 6.80. Mass spectrum molecular ion at 494. $\left.{ }^{13} \mathrm{C}_{[1} \mathrm{H} \mathrm{H}\right]$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right) \delta 123.6\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Et}_{5}\right), 79.7\left(\mathrm{OCMe}_{3}\right), 30.3\left(\mathrm{OCMe}_{3}\right), 19.3$ $\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right), 15.7\left(\mathrm{CH}_{2} \mathrm{CH}_{3}\right)$.
    (19) This type of decomposition of glycolates was proposed as the way in which tungsten(IV) halide complexes converted glycols into olefins. ${ }^{20}$
