Received July 15, 1982

#### Abstract

The stereoselectivities of the Diels-Alder reactions of six methyl-substituted norbornyl- and norbornenyl-fused cyclopentadiene systems (3-5) with various dienophiles have been examined. Whereas $\mathbf{3 a}$ enters into cycloaddition from the above-plane direction for steric reasons, the responses of $\mathbf{3 b}, \mathbf{4 c}$, and $\mathbf{5}$ are attributed to electronic influences. Molecular orbital calculations have also been carried out in support of this conclusion. The rates of dimethyl acetylenedicarboxylate cycloaddition to $\mathbf{3 a}, \mathbf{3 b}, 5$, and six related compounds provide further indication that steric factors are not the primary determinant of $\pi$-facial stereoselectivity. The use of ${ }^{13} \mathrm{C}$ NMR spectroscopy as a diagnostic for the elucidation of syn- and anti-sesquinorbornene stereochemistry is also detailed, as are the intimate intimate structural features of four adducts which have been subjected to X-ray crystal structure analysis. Particular attention is given to the extent of deformation about the central double bond.

The effect of substituents on the stereoselectivity of Diels-Alder additions to norbornyl- and norbornenyl-fused diene systems has recently received detailed attention in these laboratories. ${ }^{1,4,5}$ The remarkable contrast in the behavior of $\mathbf{1}$ (below-plane attack) and

$\stackrel{1}{\sim}$

$\underset{\sim}{2}$

2 (above-plane attack) served to raise a number of questions pertaining to the possible perturbing role of steric influences. Thus, the presence of alkyl groups in certain dienes and not others could exert a rate-retarding effect to an extent sufficient to permit a stereochemically different pathway to become dominant. The 2 -fold purpose of the present study was to extend the range of substituents to include methyl groups both directly on the cyclopentadiene ring and the apical norbornyl carbon atom, and to perform kinetic studies which would reveal in quantitative terms the impact made by these appendages on cycloaddition rate.

The monomethyl-substituted hydrocarbons $\mathbf{3 a}, \mathbf{4 a}$, and $\mathbf{4 b}$ were

$3 \mathrm{a}, \mathrm{R}_{1}=\mathrm{H}, \mathrm{R}_{2}=\mathrm{CH}_{3}$
$\underset{\sim}{\mathrm{~b}}, \mathrm{R}_{1}=\mathrm{R}_{2}=\mathrm{CH}_{3}$

available from an earlier study, ${ }^{6}$ as was the camphor-derived substrate 5. ${ }^{7}$ Synthetic approaches to 3b and $\mathbf{4 c}$ are described

[^0]below. These systems provide various types of steric encumbrance which must be superimposed upon those existing factors which normally contribute to stereoselective [ $4+2$ ] cycloaddition. Thus, the lone methyl group which is projected below the $\pi$ surface of the cyclopentadiene ring in 3 a and $\mathbf{4 a}$ can be expected to alter dienophile accessibility to the usually preferred endo face. At issue is whether this steric imbalance is adequate to modulate $\pi$-facial stereoselectivity and, if so, at what kinetic expense, if any. As concerns $\mathbf{3 b}$ and $\mathbf{4 c}$, the geminal methyl pair restores more equitable steric balance to approach from above and below the cyclopentadiene unit, but with added steric restrictions to both bonding schemes. Also to be considered if below-plane attack occurs is the extent to which nonbonded steric interactions between apical bridges (see 6) might become an issue of some consequence.

$\underset{\sim}{6}$

$\geq$

Diene 5 was studied in order to examine the complementary state of affairs depicted in transition state 7.

## Results

Synthesis. The starting material for the preparation of $\mathbf{3 b}$ and 4 c was 2,2 -dimethyl-4-cyclopentene-1,3-dione (10). Although Agosta and Smith have reported a preparation of 10 from its dihydro derivative by N -bromosucciminide oxidation, ${ }^{8}$ this procedure proved problematic in our hands. However, the alternative route later devised by Jefferson, McDonald, and Smith ${ }^{9}$ which involves the bromination of open-chain diketone 8 followed by cyclizative 2 -fold dehydrobromination of 9 delivered 10 reproducibly. Following Diels-Alder addition of $\mathbf{1 0}$ to cyclopentadiene and catalytic hydrogenation, ${ }^{8}$ endo/exo mixtures of 11 and 12 (slightly richer in the depicted endo isomers) were obtained. This stereochemical inhomogeneity presented no difficulty, and the unpurified mixtures were directly reduced with lithium trimethoxyaluminum hydride and dehydrated with phosphorus oxychloride in pyridine. ${ }^{10}$ Both resulting hydrocarbons displayed eight-line ${ }^{13} \mathrm{C}$ NMR spectra in accord with their symmetry.

Cycloadditions to 3a. Maleic anhydride added to diene 3a at room temperature in benzene solution and gave adduct 13 as the

13

14

$\stackrel{15}{\sim}$
sole observable product ( $\geq 97 \%$ ). The endo configuration of the anhydride moiety was immediately apparent from its ${ }^{1} \mathrm{H}$ NMR spectrum which shows the vicinal coupling constant between the tertiary $\alpha$-carbonyl and neighboring bridgehead protons to be $\sim 1.5$ $\mathrm{Hz} .{ }^{11}$ Its characterization as an anti-sesquinorbornene derivative rests upon ample ${ }^{13} \mathrm{C}$ analogy with adducts of established structure (Table I). The striking similarity of the chemical shifts among the four anti-endo anhydrides requires no additional comment. Although the number of known syn-endo isomers is more limited it is clear that the data for $\mathbf{1 3}$ are incompatible with this particular stereochemical assignment. Finally, as has been pointed out elsewhere, ${ }^{1}$ the apical carbon atoms of syn-exo adducts generally experience rather marked shielding relative to their stereoisomers and are usually distinguishable on this basis.

Stirring 3a with the less reactive phenyl vinyl sulfone reagent in dichloromethane for 18 days at room temperature furnished 14 as the only symmetrical adduct. ${ }^{12}$ Although the configuration of the phenylsulfonyl group was deduced to be endo from ${ }^{1} \mathrm{H}$ NMR data (vicinal bridgehead proton appears as a doublet with $J=3 \mathrm{~Hz}$ ), the molecule's topology was convincingly established only after sodium amalgam reduction ${ }^{13}$ to 15 . In this hydrocarbon, the chemical shift of the apical carbons (see formula) are downfield of those in syn-sesquinorbornene ( 50.26 ppm ), ${ }^{14}$ but compare closely with those of the anti isomer ( 54.51 ppm ). ${ }^{15}$

[^1]Methyl acrylate reacted inefficiently with 3a to give 16a and $\mathbf{1 6 b}$ in equal amounts, along with a lesser quantity of an unsym-

metrical adduct. ${ }^{16}$ The stereodisposition of the carbomethoxy groups was assigned on the basis of the relative polarity of the epimers on silica gel. The anti-sesquinorbornene character of the esters was ascertained by their mutual unreactivity toward diimide ( $97 \%$ recovery in both instances). In contrast, 17 has been shown to be readily reduced by this reagent. ${ }^{14,17}$ Consequently, dienophile capture has again proceeded stereoselectively from above the diene $\pi$ system.
$N$-Methyltriazolinedione added rapidly to 3a at $-78^{\circ} \mathrm{C}$ to produce a 93:7 mixture of urazoles 18 and 19. Although only

$\stackrel{18}{\sim}$

$\stackrel{19}{\sim}$
18 was isolated in analytically pure form, the ${ }^{13} \mathrm{C}$ NMR spectra of both isomers were recorded. As can be seen from the compilation in Table II, there exists a dichotomy in apical carbon shifts between syn and anti stereoisomers which parallels that made evident in Table I. Nonetheless, to place our assignments beyond reproach, a confirmatory X-ray crystal structure analysis was carried out on 18 (Figure 1). Of interest in connection with this highly reactive dienophile is the finding that a small percentage of below-plane attack is able to operate despite the sterically disadvantaged status of that $\pi$ surface.

Dimethyl acetylenedicarboxylate (DMAD) added to 3a at 20 ${ }^{\circ} \mathrm{C}$ with still higher below-plane stereoselectivity to give a $70: 30$ mixture of $\mathbf{2 0}$ and 21. From the compilation provided in Table

20

21

22

III, it is clear that syn/anti stereodifferentiation can be accomplished with reasonable confidence from ${ }^{13} \mathrm{C}$ data alone. Nonetheless, further confirmation was achieved by subjecting both substances to peracid epoxidation. As expected for 20, conversion to 22 was complete in less than 30 min at room temperature. For 21, only $11 \%$ conversion to epoxide was achieved after 3 days in refluxing dichloromethane. Thus, DMAD once again has exerted somewhat of a maverick role by engaging in preferential [ $4+2$ ] $\pi$-facial stereoselection opposite that observed with olefinic (as opposed to acetylenic) dienophiles. ${ }^{1}$
4a/4b-Maleic Anhydride Reaction Profile. Because of the availability of $\mathbf{4 a}$ and $\mathbf{4 b}$ only as an inseparable isomeric mixture, ${ }^{6}$ studies involving these dienes were confined to maleic anhydride. Were indiscriminate stereoselection to prevail, a total of eight cycloadducts would be formed. As matters turned out, only four

${ }^{a}$ Paquette, L. A.; Carr, R. V. C.; Böhm, M. C.; Gleiter, R. J. Am. Chem. Soc. 1980, 102, 1186, 7218. b Paquette, L. A.; Charumilind, P.; Böhm, M. C.; Gleiter, R., Bass, L. S.; Clardy, J. Ibid. 1983, 105 (second paper of this series in this issue).
products could be detected by various chromatographic techniques. It proved possible to separate these isomers by medium-pressure liquid chromatography. Their order of elution from silica gel (isolated yields given in parenthesis) was 23 ( $27 \%$ ), 24 ( $9 \%$ ), 25 (5\%), and 26 ( $25 \%$ ). The pure anhydrides were subsequently subjected to catalytic hydrogenation under controlled conditions. The dihydro compounds proved useful in facilitating structural assignments. By use of ${ }^{1} \mathrm{H}$ NMR criteria analogous to those described earlier, it was clear that the succinic anhydride moieties in 25 and 26 were oriented endo, while 23 and 24 were exo isomers. The remaining important distinctions, those concerned with the

23

25

24

$\stackrel{26}{\sim}$
syn or anti disposition of the methano bridges, were deduced primarily from ${ }^{13} \mathrm{C}$ NMR data. In Table IV, we have compiled the chemical shifts of the key carbon signals in 23-26 and their hydrogenation products.
Since $\mathbf{2 6}$ was transformed into 13 on reduction, its identification as the endo-anti isomer is considered secure. The downfield position of apical carbon $b$, a phenomenon particularly characteristic of endo anhydrides (Table I), finds added parallel in $\mathbf{2 5}$ and 29 in agreement with the proton-based assignments. In accordance with those trends noted previously, the chemical shifts of the apical carbons in syn isomers $\mathbf{2 5}$ and $\mathbf{2 9}$ are appropriately upfield on their counterparts in the anti-sesquinorbornenes. This correlation applies as well to $\mathbf{2 3 / 2 7}$ and 24/28 (Table IV). In added substantiation of these structural formalisms, we note the effect of anhydride geometry on methyl proton shielding. With adoption of an exo orientation as in $23(\delta 0.98), 24(0.82)$ and their respective dihydro derivatives $27(0.93)$ and $28(0.82)$, the chemical shifts appear relatively normal. However, an endo anhydride configuration induces a nontrivial shielding effect which displaces the methyl signals to higher field. The data for 25 (0.68), $26(0.60), 29(0.68)$, and $13(0.67)$ are exemplary.

The findings just described indicate that $\mathbf{4 a}$ and $\mathbf{4 b}$ enter into Diels-Alder addition with maleic anhydride stereospecifically from the $\pi$ surface opposite that occupied by the methyl substituent for obvious steric reasons. It is of some interest that above-plane approach to 4 a is partitioned $64 \%$ exo and $36 \%$ endo while bonding from below in $\mathbf{4 b}$ favors the exo orientation to the extent of $85 \%$. These ratios are thought simply to reflect the relative steric bulks of the etheno and methano bridges which are made apparent to the approaching maleic anhydride in the endo transition states.

Consequences of Geminal Dimethyl Substitution as in 3b and 4c. With the placement of geminal methyl substituents on the cyclopentadiene ring as in $\mathbf{3 b}$ and $\mathbf{4 c}$, a return to a more closely balanced steric situation is achieved. What then will be the effect of a methyl substituent? Will below-plane stereospecificity be observed as in the parent hydrocarbon, ${ }^{14,17}$ or will these alkyl groups perturb the diene $\pi$ orbital shapes and energies adequately to promote preferential capture from the above-plane direction? The pivotal role played in particular by $\mathbf{3 b}$ is perhaps best gauged by the diametrically opposite stereoselectivity response given by 1 and $2 .{ }^{1}$
To resolve these questions, diene $\mathbf{3 b}$ was allowed to react with maleic anhydride, $N$-phenylmaleimide, and $N$-methyltriazolinedione. In each instance, cycloaddition proceeded smoothly and efficiently to provide a single adduct (each $\geq 97 \%$ purity within our detectability limits). The structure of anhydride 30 was suggested by its spectral data and confirmed by threedimensional X-ray crystal structure analysis (Figure 2). The parallelisms between the spectra of $\mathbf{3 0}$ and $\mathbf{3 1}$ are particularly

33

34

35
${ }^{13} \mathrm{C}$ NMR spectrum (Table III) and resistance to epoxidation. Once again, therefore, the acetylenic diester has distinguished itself by engaging in kinetically controlled stereoselection predominately opposite that followed by the trio of olefinic dienophiles.

Much like the triene corresponding to $2,{ }^{1} \mathbf{4 c}$ entered only with reluctance into Diels-Alder reactions. When heated with $N$ phenylmaleimide in refluxing benzene for 6 days, a two-component cycloadduct mixture was produced in low yield. The majority of $\mathbf{4 c}$ was left unchanged. During the chromatographic process required to separate the unreacted $\mathbf{4 c}$, the major adduct was destroyed almost totally. Following catalytic hydrogenation, it proved possible to isolate 36 whose spectral features, especially

36

37
its unsubstituted apical carbon absorption at 50.73 ppm and closely spaced methyl proton signals at $\delta 1.16$ and 1.14 , identify it as the previously unknown exo-syn isomer.

In a somewhat parallel situation, $N$-methyltriazolinedione added to $\mathbf{4 c}$ at room temperature to give a $56: 44$ mixture of adducts. Medium-pressure liquid chromatographjy on silica gel served to decompose the major component. Because the remaining isomer was slowly transformed in air to a red oil, its characterization was deferred until after partial hydrogenation. The resulting stable colorless solid was shown to be 37 by a combination of ${ }^{13} \mathrm{C}$ (Table II) and ${ }^{1} \mathrm{H}$ NMR data ( $\delta_{\mathrm{CH}_{3}}=1.30$ and 1.08). Therefore, the presence of a third double bond in $\mathbf{4 c}$ serves to promote reasonable levels of competitive below-plane attack. Partial loss of stereoselectivity of comparable magnitude has been observed previously. ${ }^{1,4 a}$
$\pi$-Facial Stereoselective Behavior of 5. Maleic anhydride reacted smoothly with 5 in benzene solution at room temperature to deliver the dissymmetric adduct $\mathbf{3 8} \mathbf{( 9 8 \% )}$ ). The exo orientation

38

40

41
of the anhydride moiety as well as the syn disposition of the methano bridges were confirmed by X-ray analysis (Figure 4). The ${ }^{13} \mathrm{C}$ NMR data for 38 proved to be important adjuncts to our correlation chart (Table I). Under identical conditions, $N$-phenylmaleimide and DMAD added efficiently to 5 to give 39 and 40 as the only isolable adducts. In typical fashion, 40 underwent oxidation to 41. This demonstration of the proclivity of dienophiles of varying reactivity to add to 5 from below the $\pi$ plane conforms to the pattern originally established by isodicyclopentadiene and, more recently, the spirocyclopropane 1 . On the other hand, this preferred direction of attack is opposite that exhibited by 2 and 3 b .

Table IV. Selected ${ }^{13} \mathrm{C}$ Chemical Shifts in the Maleic Anhydride Adducts of $4 \mathrm{a} / 4 \mathrm{~b}$ and Their Dihydro Derivatives (ppm, $\mathrm{CDCl}_{3}$ Solution)

Intramolecular $\pi$-Bond Distortions in the Adducts. It is now well established that syn-sesquinorbornenes and closely allied molecules are structurally deformed in that manner which spreads the methylene bridges apart. ${ }^{1,4,15,18-21}$ The dihedral angles between the planes which flank the central double bond in the various frameworks have been determined to be $4.5-10^{\circ}$ in 42, 11.8-18.0 ${ }^{\circ}$

42

43

44
in 43, and $11.8^{\circ}$ in the one example of 44. Indeed, there appears to be a direct correlation between the number of syn-oriented norbornene rings and the level of distortion. In this connection, anhydride 38 is no exception (Table V). As its final atomic parameters, bond lengths, and bond angles denote (Tables VI-IX), the two planes of interest intersect at a $15.5^{\circ}$ angle in a downward (endo) direction (Figure 4).

[^5]

Figure 1. X-ray stereoview of $\mathbf{1 8}$ showing within molecular conformation in the crystal.

Figure 2. X-ray stereoview of 30 showing the molecular conformation in the crystal.

Figure 3. X-ray stereoview of 32 showing the molecular conformation in the crystal.

By way of comparison, anti-sesquinorbornenes show only lowlevel distortion, if any, the maximum dihedral angle deviation observed to date being $2.0^{\circ} .^{1,15}$ This is also true for 18 (Tables X-XIII, Figure 1), 30 (Tables XIV-XVIII, Figure 2), and 32 (Tables XIX-XXII, Figure 3). However, this triad of molecules provides insight into a phenomenon not previously given attention. Since their methano bridges are dissimilarly substituted, the resulting tilt will either be toward the substituted bridge or away from it in the direction of the methano bridge. In all three examples, our findings are that the respective angular distortions of $0.44^{\circ}, 0.48^{\circ}$, and $1.8^{\circ}$, small as they may be, are discretely away from the geminal methyl groups. We assign no significance to this fact at the moment except to point out that the large
intramolecular contacts suggest that nonbonded steric factors are quite likely unimportant.

Comparative Analysis of the Diels-Alder Reactivity of Tricyclo[5.2.1. $0^{2.6}$ ]decadienes toward DMAD. The $\pi$-facial stereoselectivity shown by tricyclo[5.2.1.0 2, ${ }^{2}$ ] decadienes in Diels-Alder reactions can clearly be modified by substitution of the tetrahedral carbon of the cyclopentadiene ring. These striking chemical phenomena may have their origin in (a) steric hindrance changes which selectively restrict dienophile approach from above or below the diene $\pi$ plane, (b) modifications in the energies and shapes of frontier and subjacent MO's as a consequence of through-bond and through-space orbital interactions, (c) variations in the timing of the respective transition states with a corresponding crossover

from reactant-like (when early) to product-like characteristics (when late), and (d) a combination of these influences. In an effort to acquire background kinetic information, we have also measured the rates of addition of DMAD to $1-3$ and 5, as well as to the four structurally related systems 45-48. The selection of DMAD

45

$\stackrel{47}{\sim}$

46

48
followed from the consideration of several practical matters including its heightened reactivity which enabled measurements to be made at reasonable temperatures under pseudo-first-order conditions, its lack of olefinic protons which enabled quantitative analysis of diene (or triene) disappearance in that region of the ${ }^{1} \mathrm{H}$ NMR spectrum, and its formation with certain substrates of syn- and anti-sesquinorbornadiene adduct pairs, thus enabling comparison of attack from two directions.

The reactions were conducted in $\mathrm{CDCl}_{3}$ solution with toluene as internal standard in the probe of a Bruker HX-90 FT NMR spectrometer. Close attention was paid to standardization of the experimental conditions, care being taken to set such variables as spinning rate, solution volume, tube length, etc. as rigorously
identical as possible in all runs. The cycloadditions, which were found to adhere nicely to first-order kinetics when 15 -fold excess of DMAD was used, were followed for more than 3 half-lives in all cases. For each kinetic determination, at least 25 concentration measurements of the reacting diene were taken. The pseudo-first-order rate constants ( $k_{1}$ ), which were measured at different temperatures and extrapolated to $25^{\circ} \mathrm{C}$ by standard least-squares procedures using the $\Delta H^{*}$ and $\Delta S^{*}$ values obtained from slopes of Arrhenius plots, are collected in Table XXIII. The errors reported for $E_{\mathrm{a}}$ and $\Delta H^{*}$ were calculated on the basis of the standard deviations of these slopes and the maximum uncertainty in the temperature during measurement $\left( \pm 0.5^{\circ} \mathrm{C}\right)$. The errors in $\Delta S^{*}$ were calculated from the standard deviations of the $y$ intercept values in the Arrhenius plots and may be a bit low (although systematically so). When two stereoisomers were produced, the $k_{1}\left(25^{\circ} \mathrm{C}\right)$ was factored by the product composition to give the respective rate for above- and below-plane attack.

When the rate constants for below-plane attack on 45, 3a, and 3 b are compared. a reactivity order of $950: 300: 1$ is seen at $25^{\circ} \mathrm{C}$. Thus, the presence of an endo-methyl substituent on the cyclopentadiene ring causes an approximate 3 -fold dropoff in cycloaddition rate. On the other hand, placement of a pair of methyl groups at this position causes an additional 300 -fold dropoff in reactivity. Whereas the rate retardation observed for $\mathbf{3 a}$ is attributable to the added primary steric encumbrance, this argument must be inordinately stretched for $\mathbf{3 b}$ unless methyl-methyl buttressing effects on secondary nonbonded steric interactions such as pictured in 6 gain importance in the transition state. However, our measurements indicate the kinetic behavior of 5 , whose reactivity might be attenuated to a comparable extent as indicated

${ }^{a}$ Only the rate of disappearance of the starting materials could be conveniently followed. Therefore, the activation parameters necessarily apply to combined above- and below-plane attack where this is operative.
in transition state 7, to be slightly faster than that of unsubstituted 45! As a consequence, we do not view the secondary influences delineated in 6 and 7 to be the primary factor behind the low reactivity of 3b. This conclusion is supported by the X-ray data on 38 which show the "inside" apical methyl group to be well beyond the van der Waals range of the opposed apical hydrogen. Can an electronic effect lie behind the kinetic phenomenon? The photoelectron spectroscopy studies and theoretical calculations to be described in the next section address this question.

It is of interest in this connection that $\mathbf{1}$ and 2 are 200 and 150 times, respectively, more reactive than $\mathbf{3 b}$. We see, therefore, that spiroannulation does not have as deleterious a kinetic effect as simpler geminal dimethyl substitution. Perhaps relevantly, the dimethylfulvene 46, which is known to experience appreciable electronic perturbation, ${ }^{4 \mathrm{~b}}$ also exhibits low-order reactivity (only 18 times faster than 3b). In fact, its reaction rate happens to be identical with that of triene 48 where through-space and through-bond interactions with the isolated $\pi$ orbital perturb the diene orbitals in a disadvantageous way. The $\mathbf{4 5} / 48$ reactivity difference of 5 is significantly less than that reported for the 49/50 pair ( $k_{\text {rel }}=56: 1$ ). ${ }^{22}$

49

50

As an added point, the relative rate constant for 2,3 -diethylidenenorbornane 47 is interesting. This open-chain analogue is only 2.2 times less reactive than $\mathbf{4 5}$, despite the strong likelihood that its double bonds do not enjoy a 1,4 -distance as conducive to $[4+2]$ bonding as does a cyclopentadiene ring. ${ }^{4.23}$ However, added methyl groups are positioned at the reaction centers, a feature which frequently results in modest rate acceleration. ${ }^{24}$ The influence of these opposed effects on rate appear to be rather closely balanced.
Although the systems that exhibit a propensity for above-plane attack are less numerous, certain intriguing features are already apparent. For example, while the reactivity order $\mathbf{3 a}>2>3$ b persists for both bonding schemes, the spread for above-plane stereoselectivity is appreciably smaller (33.3:12.7:1) than that for below-plane dienophile capture ( $300: 150: 1$ ). This pattern is hardly what one would expect on the basis of steric factors alone, viz.,

${ }^{a}$ Ratio variable and somewhat dependent on solvent. ${ }^{b}$ Dienophile proved insufficiently reactive for this dione. ${ }^{c}$ Ene product formation was kinetically favored.

Figure 5. Schematic representation of the deformation of the $\pi$ lobes in the lowest symmetric canonical $\pi$ orbital of 3 a .
a steric effect nonlinear in the number of methyl groups is required. The most reactive diene (3a) projects a hydrogen in the exo direction while both $\mathbf{2}$ and $\mathbf{3 b}$ have alkyl appendages protruding above the surface. Yet the reactivity differences are small in absolute terms. On the other hand, all three dienes project alkyl groups in the endo direction, a steric phenomenon which should cause kinetic leveling if steric accessibility were the principal issue and buttressing contributions were insignificant. The reactivity differences from the below-plane direction are more highly magnified by a factor of 10 . The collective results appear most cohesively interpreted in terms of the molecular orbital analysis which follows.

We interject a cautionary note here. Because DMAD is not a sterically demanding reagent, one should not extend the kinetic profile just discussed to other dienophiles. It may well be that $2 \pi$ components having greater transition-state steric requirements will generate reactivity scales differing somewhat in the diene sequence.

Theoretical Assessment of $\mathbf{3 a}, \mathbf{3 b}$, and $\mathbf{4 c}$. On the basis of earlier calculations dealing with $\mathbf{1}$ and $\mathbf{2}$, it was anticipated that $\mathbf{3 b}$ and 4b would exhibit entirely comparable interactions between their $\pi$ and $\sigma$ networks. As before, the relevant orbital energies and wave functions were derived through use of an improved INDO model. ${ }^{25}$ By means of this technique, the predicted orbital sequences for $\mathbf{3 a}, \mathbf{3 b}$, and $\mathbf{4 b}$ ( $\pi$ on top of $\sigma$ orbitals) were determined to be in agreement with the assignment of the photoelectron spectra of these hydrocarbons, ${ }^{26}$ given the usual assumption that Koopmans' theorem ${ }^{27}$ is valid for such systems. Once again, the MO calculations predict a deformation of the lowest occupied $\pi$ orbital or the diene unit, the phenomenon resulting from allowed coupling of the pure $\pi$ orbitals with delocalized $\sigma$ orbitals in the corresponding canonical MO's. The magnitude of this $\pi / \sigma$ interaction can be quantitatively estimated by means of those theoretical procedures suggested by Heilbronner and Schmelzer. ${ }^{28}$ Herein, we present an exemplary analysis of the nature of $\pi / \sigma$ interaction in 3a; the results for the other isodicyclopentadienes dealt with in this paper are entirely similar.

The lowest symmetric canonical $\pi$ orbital within 3 a shows a strong rotation of its $\pi$ lobes with respect to the plane of symmetry ( $x, z$ plane in Figure 5) in that sense wherein the p lobes at centers 1 and 4 of the diene are bent away from the methano bridge. At the same time, the p lobes at positions 2 and 3 are tilted toward this $\mathrm{CH}_{2}$ group. The relevant one-electron functions that are coupled within this linear combination are summarized in Table XXV and Figure 6. Of particular note is the finding that the symmetrical canonical $\pi$ MO contains only $62.4 \%$ pure $\pi$ con-

[^7]Table XXV. Fragmentation of the Lowest Canonical " $\pi$-orbital" of 3 a into Pure $\pi$ Functions and Precanonical $\sigma$ Linear Combinations

| MO | $\%$ |
| :--- | :--- | :--- |
| $\pi_{1}$ | 31.2 |
| $\pi_{2}$ | 31.2 |
| $\psi_{20}$ | 11.3 |
| $\psi_{29}$ | 10.0 |
| $\psi_{15}$ | 6.8 |
| $\psi_{22}$ | 2.8 |
| $\psi_{18}$ | 2.8 |

Figure 6. One-electron functions that are coupled wtihin the linear combination that generates the orbital shown in Figure 5.
tribution. The remaining contributions are given in terms of so-called precanonical orbitals, ${ }^{28}$ the largest $\sigma$ admixtures arising from the MO's $\psi_{20}$ and $\psi_{29}$. The precanonical MO $\psi_{20}$ is localized predominantly at the methano bridge of the norbornyl fragment and the $\mathrm{CHCH}_{3}$ unit of the pentadienyl ring. On the other hand, orbital $\psi_{29}$ is a typical $\sigma$-ribbon orbital with significant coefficients at the four carbon centers from the $\pi$ system. It is precisely this combination that leads to the strong deformation of the $\pi$ lobes in the corresponding canonical MO. Precanonical MO's $\psi_{15}$ and $\psi_{22}$ contain large contributions at the $\mathrm{CH}_{2}$ bridge while $\psi_{18}$ is localized at the $\mathrm{CHCH}_{3}$ unit of the pentadiene ring. This analysis reveals the deformation of the lowest occupied $\pi$ orbital of 3a (Figure 5) to be influenced by the norbornyl moiety as well as by those other substituents bonded to the cyclopentadiene ring.

The above-plane stereoselectivity (anti to the $\mathrm{CH}_{3}$ group) observed in cycloaddition reactions to 3 a is thus due not only to steric effects $\left(\mathrm{CH}_{3}\right.$ group) but also to electronic factors. The antibonding four-center four-electron interaction between the symmetrical $\pi$ MO of $\mathbf{3 a}$ and the $\pi$ orbital of the dienophile is smaller if the dienophile approaches from the side anti to the methyl group. Perturbational calculations have shown that the energy difference

Figure 7. Lowest occupied $\pi$ orbital in $\mathbf{3 b}$ as determined by the INDO procedure.
for the approach from above and below the pentadienyl plane amounts to $5-20 \mathrm{~kJ} / \mathrm{mol}$. ${ }^{14}$

The deformation of the lowest occupied $\pi$ orbital in $\mathbf{3 b}$ within the INDO framework is shown schematically in Figure 7. A rotation identical with that in $3 a$ is predicted with respect to the $x, z$ plane. That is, the $\pi$ lobes at the terminal carbon atoms of the diene are again rotated away from the methylene group. Interestingly, there is seen to be superimposed on this rotation a second one in which the terminal $p$ lobes are further bent toward the $\mathrm{CH}_{3}$ groups, while those at centers 2 and 3 of the diene unit are turned toward the $\mathrm{CH}_{2}$ bridge (Figure 7).

Rotation of the lowest occupied $\pi$ orbital of $\mathbf{3 b}$ in this manner favors attack of a dienophile from above as in 3a. The observed preference of the endo configuration of maleic anhydride or $N$-phenylmaleimide can be interpreted in terms of a secondary orbital interaction between the HOMO of the diene unit and the LUMO of the anhydride group. The situation is more complex if the dienophile has a second occupied MO with a $\pi$ system perpendicular to the first one as in DMAD or the triazolinedione. With dienophiles of this type, possible coupling between additional occupied MO's and the symmetrical $\pi$ combination of a diene unit must be taken into account. This could well give rise to a dynamically induced $\pi / \sigma$ coupling that modifies the orientation of the $\pi$ lobes. In these cases, a detailed investigation of those interactions prevailing in the transition state is necessary since the simple static model fails.

The deformation of the $\pi$ functions in $\mathbf{4 c}$ parallels the results obtained for 3b. The additional double bond does not lead to a topologically different rotation of the $\pi$ orbitals. The $\pi / \sigma$ interactions in 5 are too weak to rationalize the stereochemistry of the cycloadditions observed, at least in terms of our time-dependent static model.

## Discussion

Stepwise analysis of those factors which control the stereochemical outcome of Diels-Alder additions to tricyclo[5.2.1.0 ${ }^{2,6}$ ]decadienes and -trienes requires two assumptions. The advocacy of kinetic control takes its justification largely from the internal consistency of a large number of observations. While reversibility is not discounted, it is required that product stereochemistry not be affected by the existence of an equilibrium. At least two examples of this phenomenon have been clearly delneated. ${ }^{46,20}$ The second salient point deals with transient $\pi$ complex formation which, if involved, is amalgamated for simplicity into the overall product-controlling reaction profile (Curtin-Hammett principle).

If the preceding considerations are as firm as they appear to be, the observed above-plane/below-plane ratios must be dictated by electronic or steric factors, or a combination of these effects. At first glance, the cycloaddition stereoselectivities for alkylsubstituted tricyclo[5.2.1. $0^{2,6}$ ]decadienes summarized in Table XXIV appear somewhat indiscriminate, although almost always heavily biased in one direction or the other. Mere comparison of the cycloaddition stereoselectivities of 3 a and $\mathbf{4 5}$ reveals that the presence of an endo-methyl substituent is adequate to favor above-plane bonding except when DMAD is involved. However, a purely steric analysis does not account for the variability in stereoselection which is observed as one proceeds from 45 and 1 (below-plane) to 3b and 2 (above-plane). All four dienes are equivalently substituted on both faces of the cyclopentadiene ring and share in common the proximity of a fused norbornane ring. Without doubt, dienophiles should engage in bonding to the less sterically encumbered parent diene 45 (and to 5 as well) more readily than to the three alkylated congeners and this is borne
out by the kinetic data (Table XXIII).
Vogel has argued that cycloaddition stereoselectivity in these systems may be governed by the relative stabilities of the isomeric adducts. ${ }^{20}$ In these terms, the closely similar structures of $\mathbf{1 , 2}$, and 3b should lead to entirely comparable product profiles. Our findings demonstrate that the behavior of $\mathbf{1}$ is distinctively different (although comparable to that of 45) and lends no credence to this proposal.

Rather, electronic influences which are modifiable by the type of alkyl substitution provide the most satisfying rationalization of the stereochemical crossovers which are seen. The first key to a solution is found in $\mathbf{4 5}$ where the $\sigma$ orbitals of the norbornane framework have been shown through calculations to mix appreciably with the subjacent diene $\pi_{s}$ orbital. This interaction induces disrotatory tilting toward the methano bridge in the diene orbitals which in turn minimizes the level of antibonding interaction with the approaching dienophile on the endo face. ${ }^{14,29}$ In 1, a superimposition of interactions from the Walsh orbitals of the spiroannulated cyclopropane ring takes place. Importantly, the resulting linear combinations do not deform the orbital tilting originally present in $\mathbf{4 5}$ and, in fact, act to reinforce this effect. ${ }^{1}$ The net result is favored below-plane dienophile capture in both systems. In fulvene $\mathbf{4 8}$, pronounced rotation of the $\pi$ lobes is again seen, but restricted only to the longitudinal axis. ${ }^{4 b}$ Below-plane stereoselectivity continues to be overwhelmingly preferred.
When the special effects of a three-membered ring or external double bond are removed and replaced by more usual alkyl substitution as in 2-4, terminal diene $\pi$ orbital deformation materializes as before. In these situations, however, the lobes are rotated outwardly from the apical $\mathrm{CH}_{2}$ group, a phenomenon which is spectroscopically observable. ${ }^{4 c}$ The level of antibonding interaction between $\pi_{\mathrm{s}}$ of the diene moiety and the dienophile HOMO now becomes considerably smaller for above-plane attack and leads to anti-sesquinorbornene products.
It is quite possible that the orbital distortions to which we refer have kinetic consequences as well. The weight of evidence in Table XXIII is, however, inadequate to serve as the sole basis for distinguishing these subtle effects. This equivocation arises because our kinetic investigations have so far been restricted to DMAD, an acetylenic dienophile; certainly, a broader range of electrondeficient olefins (particularly those that behave with "cleaner" stereoselectivity) must be examined in order to define with confidence any possible interrelationship between eelctronic topology and rate.

## Experimental Section

Melting points were determined with a Thomas-Hoover apparatus and are uncorrected. The ${ }^{1} \mathrm{H}$ NMR spectra were determined with Varian EM-390 and Bruker HX-90 instruments, and apparent splittings are given in all cases. The ${ }^{13} \mathrm{C}$ spectra were obtained with a Bruker WP-80 spectrometer. Mass spectra were measured on an AEI-MS9 spectrometer at an ionizing energy of 70 eV . Microanalytical determinations were performed at the Scandinavian Microanalytical Laboratory, Herlev, Denmark.

(29) Paquette, L. A.; Carr, R. V. C.; Arnold, E.; Clardy, J. J. Org. Chem. 1980, 45, 4907.
evaporated and the residue was subjected to preparative TLC on silica gel (elution with $10 \%$ ethyl acetate in hexane). The more rapidly eluted adduct ( $410 \mathrm{mg}, 38 \%$ ), white needles, $\mathrm{mp} 128-129.5^{\circ} \mathrm{C}$ (from ether) was identified as 14: ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 8.0-7.8(\mathrm{~m}, 2 \mathrm{H}), 7.67-7.40(\mathrm{~m}$, 3 H ), 3.1-2.6 (m, 6 H), 2.4-2.1 (m, 1 H), 1.9-1.03 (m, 7 H ), 0.63 (d, $J=6 \mathrm{~Hz}, 3 \mathrm{H}$ ); ${ }^{13} \mathrm{C}$ NMR ( $\mathrm{ppm}, \mathrm{CDCl}_{3}$ ) $155.65,150.36,140.45,133.32$, $129.24,128.22,66.85,56.46,55.35,49.33,46.75,41.27,40.93,31.61$, $25.49,25.25,11.75$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 314.1340 ; obsd, 314.1349.

Anal. Calcd for $\mathrm{C}_{19} \mathrm{H}_{22} \mathrm{O}_{2} \mathrm{~S}: \mathrm{C}, 72.57 ; \mathrm{H}, 7.05$. Found: $\mathrm{C}, 72.46$; H, 7.08.

Also isolated was a more polar adduct which has been tentatively assigned structure i solely on the basis of its spectra: 300 mg ( $28 \%$ );

colorless crystals, mp $107-108{ }^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ $\delta 7.86-7.43(\mathrm{~m}, 5 \mathrm{H}), 5.16(\mathrm{~s}, 1 \mathrm{H}), 3.56-3.40(\mathrm{~m}, 1 \mathrm{H}), 2.76(\mathrm{br} \mathrm{s}, 1$ H), 2.20 (br s, 1 H ), $1.40(\mathrm{~s}, 3 \mathrm{H}), 1.96-1.26(\mathrm{~m}, 10 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $163.12,141.37,133.12,128.99,128.41,116.95,70.10,60.93$, $58.79,57.63,41.95,39.47,38.74,34.13,31.51,24.61,19.32$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 314.1340 ; obsd, 314.1346.

Reduction Desulfonylation of 14 . Into a stirred mixture of $6 \%$ sodium amalgam ( 2.0 g ) and disodium hydrogen phosphate ( $400 \mathrm{mg}, 0.80 \mathrm{mmol}$ ) in 20 mL of anhydrous methanol was syringed a solution of $14(250 \mathrm{mg}$ 0.80 mmol ). After 4 days, pentane ( 50 mL ) and water ( 50 mL ) were added, and the organic phase was separated after shaking. Following drying and solvent evaporation, the residue was taken up in pentane and eluted through a column of basic alumina. The eluate was evaporated to give 93 mg of a mixture of two hydrocarbons. VPC purification (12 $\mathrm{ft} \times 0.25 \mathrm{in} .5 \% \mathrm{SE} 30,150^{\circ} \mathrm{C}$ ) gave pure $15(31 \mathrm{mg}, 23 \%):{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.77(\mathrm{~m}, 2 \mathrm{H}), 2.47(\mathrm{~m}, 2 \mathrm{H}), 2.05-1.63$ (series of $\left.\mathrm{m}, 5 \mathrm{H}\right)$, $1.40-0.90$ (series of m, 6 H ), $0.63\left(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}\right.$ ); ${ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right) 150.16,58.94,55.39,47.38,40.93,27.62,25.88,12.72$.

The minor unsymmetrical component ( $16.3 \mathrm{mg}, 6 \%$ ) was not identified: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 2.93(\mathrm{~m}, 2 \mathrm{H}), 2.80(\mathrm{~m}, 2 \mathrm{H}), 2.20-1.05$ (series of m, 10 H ), $0.80(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $157.01,150.26,54.76,53.60,50.30,43.40,43.06,42.53,35.10,34.28$, 25.73, 20.24
anti-Methyl $1,2,3,4,5,6,7,8$-Octahydro-10-methyl-1,4:5,8-dimethano-naphthalene-2-carboxylates (16). A solution of 3 a ( $1.60 \mathrm{~g}, 10.9 \mathrm{mmol}$ ) and methyl acrylate ( $1.76 \mathrm{~g}, 20.5 \mathrm{mmol}$ ) in carbon tetrachloride ( 2 mL ) was placed in a stoppered flask and stirred magnetically at $42^{\circ} \mathrm{C}$ for 4 days. TLC and VPC analysis showed that ca. 40\% of 3a remained after this time. The solvent was evaporated and the residue was subjected to preparative TLC on silica gel (triple elution with $2 \%$ ethyl acetate in hexane). There was isolated $147 \mathrm{mg}(10 \%)$ of 16 a as a colorless oil: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.67(\mathrm{~s}, 3 \mathrm{H}), 3.0-2.7(\mathrm{~m}, 3 \mathrm{H}), 2.6-1.2$ (series of m , $11 \mathrm{H}), 0.63(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) 176.91, 153.17 , $150.74,56.85,55.44,51.70,51.56,47.09,46.02,41.17,41.0233 .45$, $25.73,25.59,12.14$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 232.1463 ; obsd, 232.1466.

The next less polar component proved to be 16b: a colorless oil; 141 $\mathrm{mg}(10 \%) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.63(\mathrm{~s}, 3 \mathrm{H}), 3.20-2.50(\mathrm{~m}, 5 \mathrm{H})$, $2.27-1.13$ (series of m, 9 H ), $0.63\left(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}\right.$ ); ${ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $175.31,152.40,147.59,60.10,54.67,51.36,51.27,47.68,45.59$, $41.46,41.02,32.04,25.83,25.68,12.28$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 232.1463; obsd, 232.1458 .

A third colorless oil ( $52 \mathrm{mg}, 4 \%$ ) tentatively formulated as ii was also

$\underset{\sim}{i}$
isolated: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 5.06(\mathrm{~s}, 1 \mathrm{H}), 3.67(\mathrm{~s}, 3 \mathrm{H}), 2.83$ (br s, $1 \mathrm{H}), 2.80-2.63(\mathrm{~m}, 1 \mathrm{H}), 2.27(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 1.43(\mathrm{~s}, 3 \mathrm{H}), 2.20-1.13$ (series of m, 10 H ) ${ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) 175.36, 164.10, 117.20, 61.61, 57.92, 56.56, 51.17, 49.37, 41.95, 39.76, 38.84, 34.23, 31.80, 25.78, $24.86,19.23$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 232.1463; obsd, 232.1469
anti-1,4,5,6,7,8-Hexahydro- $\boldsymbol{N}, 10$-dimethyl-1,4:5,8-dimethano-phthalazine-2,3-dicarboximides ( 18 and 19). A. NMR Tube Experiment. $N$-Methyltriazolinedione ( $147 \mathrm{mg}, 1.30 \mathrm{mmol}$ ) dissolved in $\mathrm{CDCl}_{3}$ (2
mL ) was added to a cold ( $-78^{\circ} \mathrm{C}$ ) solution of $3 \mathrm{a}(190 \mathrm{mg}, 1.30 \mathrm{mmol})$ in 1 mL of the same solvent. After 15 min , the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of this reaction mixture were recorded. The presence of a minor adduct ( $\leq 7 \%$ ) was detected by ${ }^{13} \mathrm{C}$ NMR spectroscopy, and its spectrum (and percentage) was determined by peak subtraction

For 19: ${ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $161.23,151.72,68.02,63.16,54.52$, 41.61, 25.68, 25.34, 14.03
B. Preparative-Scale Experiment. A cold $\left(-40^{\circ} \mathrm{C}\right)$, magnetically stirred solution of 3 a ( $500 \mathrm{mg}, 3.42 \mathrm{mmol}$ ) in ethyl acetate was treated dropwise with a solution of $N$-methyltriazolinedione ( $390 \mathrm{mg}, 3.42 \mathrm{mmol}$ ) in the same solvent ( 5 mL ). The disappearance of the pink color occurred rapidly and a colorless precipitate formed slowly. After 1 h at this temperature, the reaction mixture was concentrated to a volume of 2 mL , cooled to $-78^{\circ} \mathrm{C}$, and filtered to give 400 mg of 18 . The filtrate was evaporated and the residue was recrystallized from ethyl acetate-hexanes to furnish an additional 115 mg (total yield $58 \%$ ) of $\mathbf{1 8}, \mathrm{mp} 151-153^{\circ} \mathrm{C}$ dec (from ether). The minor adduct was not isolated in pure form.

For 18: ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 4.73(\mathrm{~m}, 2 \mathrm{H}), 2.98(\mathrm{~m}, 3 \mathrm{H}), 2.90(\mathrm{~s}$, $3 \mathrm{H}), 1.97-1.78(\mathrm{~m}, 2 \mathrm{H}), 1.48-1.00(\mathrm{~m}, 4 \mathrm{H}), 0.71(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H})$; ${ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $161.28,148.36,69.08,58.74,55.54,40.97$, $25.34,25.05,10.49$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 259.1321 ; obsd, 259.1314.

Anal. Calcd for $\mathrm{C}_{14} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}_{2}$ : $\mathrm{C}, 74.97 ; \mathrm{H}, 7.55$. Found: $\mathrm{C}, 74.86$; H, 74.9.

Dimethyl anti-1,4,5,6,7,8-Hexahydro-10-methyl-1,4:5,8-dimethano-naphthalene-2,3-dicarboxylates ( 20 and 21). A solution of 3a ( 460 mg , 3.17 mmol ) in chloroform ( 30 mL ) was treated with dimethyl acetylenedicarboxylate ( $450 \mathrm{mg}, 3.17 \mathrm{mmol}$ ), stirred at $20^{\circ} \mathrm{C}$ for 3 h , and freed of solvent in vacuo. The residue was purified by MPLC on silica gel (elution with $15 \%$ ethyl acetate in hexane). Two adducts were formed in a 65:35 ratio (recorder integration).

For 20: colorless oil ( $53 \mathrm{mg}, 58 \%$ ); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.70(\mathrm{~s}, 6$ $\mathrm{H}), 3.36(\mathrm{~s}, 2 \mathrm{H}), 2.98(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 1.53-1.26(\mathrm{~m}, 5 \mathrm{H}), 1.06(\mathrm{~d}, J=6$ $\mathrm{Hz}, 3 \mathrm{H}), 0.60-0.43(\mathrm{~m}, 2 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $166.52,159.63$, $147.54,77.05,57.43,51.95,48.11,43.01,22.62,13.30$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 288.1361; obsd, 288.1369.

For 21: colorless oil ( $240 \mathrm{mg}, 26 \%$ ); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.77(\mathrm{~s}, 6$ $\mathrm{H}), 3.53(\mathrm{~s}, 2 \mathrm{H}), 3.10(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 2.00-1.73(\mathrm{~m}, 2 \mathrm{H}), 1.50-1.10(\mathrm{~m}$, 5 H ), $0.70(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) 165.84, 158.71, $155.16,83.70,57.43,55.35,51.85,42.53,25.68,13.93$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 288.1361 ; obsd, 288.1366 .

Epoxidation of 20. A solution of $m$-chloroperbenzoic acid ( 290 mg , 1.67 mmol ) in dichloromethane ( 10 mL ) was added dropwise to a stirred solution of $20(400 \mathrm{mg}, 1.39 \mathrm{mmol})$ in the same solvent $(40 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$. The reaction mixture was stirred at room temperature for 30 min and washed with $10 \%$ sodium thiosulfate and saturated sodium bicarbonate solutions and water prior to drying. Following solvent evaporation, the residual oil was purified by MPLC on silica gel (elution with $15 \%$ ethyl acetate in hexanes). There was isolated 400 mg ( $95 \%$ ) of 22: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.77(\mathrm{~s}, 6 \mathrm{H}), 3.07(\mathrm{~s}, 2 \mathrm{H}), 2.60(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 2.00-1.70(\mathrm{~m}$, $2 \mathrm{H}), 1.53-1.13(\mathrm{~m}, 5 \mathrm{H}), 0.90(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right) 165.65,146.86,65.98,60.10,53.79,52.24,40.15,38.94,25.05$, 11.07; mass spectrum, $m / e\left(\mathrm{M}^{+}-\mathrm{CH}_{3}\right)$ calcd, 289.1076; obsd, 289.1084 .

Epoxidation of 21. A solution of $m$-chloroperbenzoic acid ( 130 mg , 0.75 mmol ) and 21 ( $180 \mathrm{mg}, 0.62 \mathrm{mmol}$ ) in dichloromethane ( 50 mL ) was heated at the reflux temperature for 3 days. Workup in the predescribed manner and MPLC purification as before afforded 20 mg ( $11 \%$ ) of epoxide as a colorless oil; ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.88(\mathrm{~s}, 6 \mathrm{H})$, $3.33(\mathrm{~s}, 2 \mathrm{H}), 2.76(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 2.10-1.95(\mathrm{~m}, 2 \mathrm{H}), 1.77-1.60(\mathrm{~m}, 5 \mathrm{H})$, $1.30(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $164.63,146.71,73.02$, $60.06,52.14,52.00,39.81$ (3C), 26.46; 15.34 ; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$ calcd, 304.1311 ; obsd, 304.1319.

Maleic Anhydride Addition to 4a/4b. A magnetically stirred solution of a $1: 1$ mixture of $\mathbf{4 a}$ and $\mathbf{4 b}(200 \mathrm{mg}, 1.39 \mathrm{mmol})$ and maleic anhydride ( $136 \mathrm{mg}, 1.39 \mathrm{mmol}$ ) in benzene ( 25 mL ) was heated at the reflux temperature overnight. Following the evaporation of solvent, the residue was subjected to MPLC on silica gel (elution with 20\% ethyl acetate in petroleum ether). Four products were isolated (the first two were partially overlapped and required rechromatography to achieve separation).

Fraction 1, 23 ( $90 \mathrm{mg}, 27 \%$ ): mp $156-158{ }^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \beta 6.53(\mathrm{t}, J=1.5 \mathrm{~Hz}, 2 \mathrm{H}), 3.43(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 3.28$ (s. $2 \mathrm{H}), 2.43(\mathrm{~s}, 2 \mathrm{H}), 2.4-2.0(\mathrm{~m}, 3 \mathrm{H}), 0.98(\mathrm{~d}, J=6 \mathrm{~Hz}, 3 \mathrm{H}),{ }^{3} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $172.35,159.48,139.48,70.83,52.68,50.25,48.65,47.34$, 11.07; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 242.0943; obsd, 242.0950 .

$26 \rightarrow$ 13: mp $108-109^{\circ} \mathrm{C}$; spectral properties identical with those reported earlier.

4,5,6,7-Tetrahydro-2,2-dimethyl-4,7-methano-2H-indene (3b). A cold $\left(0^{\circ} \mathrm{C}\right)$, stirred suspension of lithium aluminum hydride $(6.15 \mathrm{~g}, 0.162$ mmol ) in dry tetrahydrofuran ( 350 mL ) was treated dropwsie under nitrogen with dry methanol ( $19.8 \mathrm{~mL}, 0.487 \mathrm{~mol}$ ). Following 30 min at $0^{\circ} \mathrm{C}$, a solution of $\mathbf{1 2}(5.8 \mathrm{~g}, 0.030 \mathrm{~mol})$ in dry tetrahydrofuran $(60 \mathrm{~mL})$ was added dropwise over 15 min at $0^{\circ} \mathrm{C}$. The reaction mixture was stirred at $25^{\circ} \mathrm{C}$ for 5 h , treated dropwise with water ( 250 mL ) with external cooling, and filtered. The separated solids were leached with dichloromethane ( $2 \times 250 \mathrm{~mL}$ ), and the combined filtrates were washed with $10 \%$ hydrochloric acid ( 200 mL ) and water ( 200 mL ) prior to drying. Solvent evaporation left $5.1 \mathrm{~g}(86 \%)$ of diol isomers obtained as a colorless solid, $\mathrm{mp} 140-141^{\circ} \mathrm{C}$ (from hexanes). For the major component: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.64(\mathrm{~m}, 2 \mathrm{H}), 2.65(\mathrm{~m}, 6 \mathrm{H}), 2.5(\mathrm{~m}, 2$ $\mathrm{H}, \mathrm{OH}), 2.0-0.93(\mathrm{~m}, 4 \mathrm{H}), 1.10(\mathrm{~s}, 3 \mathrm{H}), 0.93(\mathrm{~s}, 3 \mathrm{H})$; mass spectrum, $\mathrm{m} / \mathrm{e}\left(\mathrm{M}^{+}-2\right)$ calcd, 194.1307; obsd, 194.1311.

Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{20} \mathrm{O}_{2}: \mathrm{C}, 73.43 ; \mathrm{H}, 10.27$. Found: $\mathrm{C}, 73.31$; H, 10.28 .

A solution of the diol ( $2.55 \mathrm{~g}, 13 \mathrm{mmol}$ ) in dry pyridine ( 43 mL ) was stirred at room temperature under nitrogen while freshly distilled phosphorus oxychloride ( $2.6 \mathrm{~mL}, 28 \mathrm{mmol}$ ) was added dropwise over 2 min . The reaction mixture was stirred at room temperature for 15 min , boiled for 15 min , cooled, and poured onto ice containing a little hydrochloric acid. The product was extracted into ether $(2 \times 75 \mathrm{~mL})$ and washed with $10 \%$ hydrochloric acid ( $3 \times 100 \mathrm{~mL}$ ), saturated sodium bicarbonate solution, water, and brine prior to drying. Solvent evaporation left a yellow oil, distillation of which afforded diene $\mathbf{3 b}$ as a colorless liquid $(0.70 \mathrm{~g}, 34 \%) ; \mathrm{bp} 60-62^{\circ} \mathrm{C}(3 \mathrm{~mm}){ }^{\mathrm{J}} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 5.40(\mathrm{~s}, 2 \mathrm{H})$, $2.90(\mathrm{~m}, 2 \mathrm{H}), 2.0-1.6(\mathrm{~m}, 4 \mathrm{H}), 1.6-1.3(\mathrm{~m}, 2 \mathrm{H}), 1.20(\mathrm{~s}, 3 \mathrm{H}), 1.17$ $(\mathrm{s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $150.55,128.02,57.77,45.15,38.16$, $28.79,23.55,22.91$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 160.1252 ; obsd, 160.1257.

4,7-Dihydro-2,2-dimethyl-4,7-methano-2H-indene (4c). A 3.0 g ( 15.8 mmol ) sample of 11 was reduced with lithium aluminum hydride ( 3.21 $\mathrm{g}, 85 \mathrm{mmol}$ ) and methanol ( $10.34 \mathrm{~mL}, 0.255 \mathrm{~mol}$ ) in dry tetrahydrofuran ( 180 mL ) as described above. After the same workup, there was isolated $2.8 \mathrm{~g}(91 \%)$ of a pale yellow solid, recrystallization of which from hexanes gave the diol isomers as a colorless crystalline solid, $\mathrm{mp} 149-150^{\circ} \mathrm{C}$. For the major component: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{COCD}_{3}\right) \delta 6.03(\mathrm{t}, J=2 \mathrm{~Hz}, 2$ $\mathrm{H}), 3.55(\mathrm{~m}, 2 \mathrm{H}), 3.2-2.6(\mathrm{~m}, 6 \mathrm{H}), 1.5(\mathrm{~m}, 2 \mathrm{H}), 1.00(\mathrm{~s}, 3 \mathrm{H}), 0.95$ (s, 3 H ).

Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{18} \mathrm{O}_{2}: \mathrm{C}, 74.19 ; \mathrm{H}, 9.34$. Found: $\mathrm{C}, 74.03 ; \mathrm{H}$, 9.35 .

Treatment of the diol mixture ( $2.8 \mathrm{~g}, 14.4 \mathrm{mmol}$ ) in dry pyridine ( 45 $\mathrm{mL})$ with phosphorus oxychloride $(2.88 \mathrm{~mL}, 31 \mathrm{mmol})$ in the predes-
cribed manner gave a yellow oil ( 1.70 g ). Distillation gave $\mathbf{4 c}(370 \mathrm{mg}$, $16 \%$ ) as a faintly yellow oil, bp $48-53^{\circ} \mathrm{C}(1.75 \mathrm{~mm})$. The product was collected at $-78^{\circ} \mathrm{C}$ and stored in a freezer under nitrogen. The hydrocarbon was distilled an additional two times prior to PE analysis: ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ) $\delta 6.20(\mathrm{t}, J=2 \mathrm{~Hz}, 2 \mathrm{H}), 5.38(\mathrm{~s}, 2 \mathrm{H}), 3.28(\mathrm{~m}, 2 \mathrm{H})$, 2.14 (brd, $J=8 \mathrm{~Hz}, 1 \mathrm{H}), 1.88(\mathrm{brd}, J=8 \mathrm{~Hz}, 1 \mathrm{H}), 1.18(\mathrm{~s}, 3 \mathrm{H})$, $1.08(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right)$ 148.61, 137.49, 128.22, 59.96, 57.77, 43.21, 24.13, 22.58; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 158.1095 ; obsd, 158.1100.
endo ,anti $-1,2,3,4,5,6,7,8$-Octahydro-10,10-dimethyl-1,4:5,8-di-methanonaphthalene-2,3-dicarboxylic Anhydride (30). A solution of 3b ( $200 \mathrm{mg}, 1.25 \mathrm{mmol}$ ) and maleic anhydride ( $120 \mathrm{mg}, 1.25 \mathrm{mmol}$ ) in benzene ( 4 mL ) was heated at the reflux temperature under a nitrogen atmosphere for 86 h . Solvent evaporation left 320 mg ( $100 \%$ ) of a single adduct: colorless crystalline solid, mp $114-115^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.77(\mathrm{~m}, 2 \mathrm{H}), 2.92(\mathrm{~m}, 4 \mathrm{H}), 1.85(\mathrm{brd}, 2 \mathrm{H})$, $1.65-1.10(\mathrm{~m}, 4 \mathrm{H}), 1.0(\mathrm{~s}, 3 \mathrm{H}), 0.82(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right)$ $172.23,151.47,69.24,54.56,53.52,48.49,42.12,24.82,22.88,21.00$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 258.1256 ; obsd, 258.1265.

Anal. Calcd for $\mathrm{C}_{16} \mathrm{H}_{18} \mathrm{O}_{3}$ : C, $74.40 ; \mathrm{H}, 7.02$. Found: C, $74.40 ; \mathrm{H}$, 7.08 .
$1,2,3,4,5,6,7,8$-Octahydro- 10,10 -dimethyl- $\boldsymbol{N}$-phenyl-1,4:5,8-di-methanonaphthalene-2,3-dicarboximide (31). A solution of 3b ( 200 mg , 1.25 mmol ) and $N$-phenylmaleimide ( $220 \mathrm{mg}, 1.25 \mathrm{mmol}$ ) in chloroform ( 4 mL ) was heated at the reflux temperature under nitrogen for 5 days. Evaporation of solvent gave a yellowish solid, the ${ }^{1} \mathrm{H}$ NMR spectrum of which indicated it to be homogeneous. MPLC purification on silica gel (elution with $10 \%$ ethyl acetate in hexanes) gave 350 mg ( $83 \%$ ) of 31 as a colorless solid: mp $168.5-169^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ) $\delta 7.45-7.10(\mathrm{~m}, 5 \mathrm{H}), 3.53(\mathrm{~m}, 2 \mathrm{H}), 2.82(\mathrm{~m}, 4 \mathrm{H}), 1.9-1.55(\mathrm{~m}, 2 \mathrm{H})$, $1.32-1.05(\mathrm{~m}, 4 \mathrm{H}), 1.0(\mathrm{~s}, 3 \mathrm{H}), 0.72(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right)$ $177.14,150.62,132.17,128.78,127.80,125.74,69.00,53.65,53.22$, 47.46, 42.06, 24.88, 23.12, 21.42; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 333.1729; obsd, 333.1736 .

Anal. Calcd for $\mathrm{C}_{2 \mathrm{i}} \mathrm{H}_{23} \mathrm{NO}_{2}$ : $\mathrm{C}, 79.25 ; \mathrm{H}, 6.95$. Found: $\mathrm{C}, 79.19$; H, 7.00 .
anti-1,4,5,6,7,8-Hexahydro- $N, 10,10$-trimethyl-1,4:5,8-dimethano-phthalazine-2,3-dicarboximide (32). A solution of 3b ( $200 \mathrm{mg}, 1.25$ mmol ) in ethyl acetate ( 5 mL ) was treated dropwise with a solution of $N$-methyltriazolinedione ( $140 \mathrm{mg}, 1.25 \mathrm{mmol}$ ) in the same solvent ( 5 mL ) at $-78^{\circ} \mathrm{C}$ under a dry nitrogen atmosphere. The reaction mixture was stirred at $-78^{\circ} \mathrm{C}$ for 30 min , allowed to warm to room temperature, and evaporated. Chromatography of the residue on silica gel (elution with $20 \%$ ethyl acetate in hexanes) gave $340 \mathrm{mg}(100 \%)$ of 32 : colorless crystals, $\mathrm{mp} 128-130^{\circ} \mathrm{C}$ dec (from hexanes); ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 4.47$ $(\mathrm{s}, 2 \mathrm{H}), 3.00(\mathrm{~m}, 2 \mathrm{H}), 2.90(\mathrm{~s}, 3 \mathrm{H}), 1.85(\mathrm{~m}, 2 \mathrm{H}), 1.4-0.9(\mathrm{~m}, 4 \mathrm{H})$, $1.3(\mathrm{~s}, 3 \mathrm{H}), 0.8(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) 161.52, 148.95, 72.29, $64.23,55.25,41.36,25.34,24.66,21.89,19.71$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$ calcd, 273.1477; obsd, 273.1485.

Anal. Calcd for $\mathrm{C}_{15} \mathrm{H}_{19} \mathrm{~N}_{3} \mathrm{O}_{2}: \mathrm{C}, 65.91 ; \mathrm{H}, 6.99$. Found: $\mathrm{C}, 65.92$; H, 7.01 .
syn- and anti-Dimethyl $1,4,5,8$-Tetrahydro-10,10-dimethyl-1,4:5,8-dimethanonaphthalene-2,3-dicarboxylates ( 33 and 34). A solution of 3 b ( $100 \mathrm{mg}, 0.625 \mathrm{mmol}$ ) and dimethyl acetylenedicarboxylate ( 160 mg , 1.13 mmol ) in chloroform ( 2 mL ) was stirred under nitrogen at room temperature for 7 h . Solvent evaporation, followed by removal of starting materials at 0.3 mm , gave 180 mg of an oil. MPLC purification on silica gel (elution with $10 \%$ ethyl acetate in hexanes) gave major adduct 33 ( 140 mg ) and minor component $34(40 \mathrm{mg}$ ) (total yield $90 \%$ ).

For 33: oil; ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 3.75(\mathrm{~s}, 6 \mathrm{H}), 3.30(\mathrm{~s}, 2 \mathrm{H}), 2.95$ (br s, 2 H ), $1.7-1.1$ (m, 4 H ), 1.28 (br s, 6 H ), 0.55 (br d, 2 H ); ${ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) 166.57, 157.30, 149.34, 82.63, 61.95, 51.90, 48.16, 42.87, 24.03, 22.72, 22.43; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 302.1518 ; obsd, 302.1525.

For 34: oil; ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 3.75(\mathrm{~s}, 6 \mathrm{H}), 3.32(\mathrm{~s}, 2 \mathrm{H}), 3.05$ (m, 2 H$), 1.9-1.0(\mathrm{~m}, 6 \mathrm{H}), 1.20(\mathrm{~s}, 3 \mathrm{H}), 0.87(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right) 166.28,159.97,153.46,88.02,62.38,55.59,51.85,43.01,25.15$, 23.98, 22.72; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 302.1518 ; obsd, 302.1525 .

Peracid Epoxidation of 33. A solution of $33(270 \mathrm{mg}, 0.894 \mathrm{mmol})$ and $m$-chloroperbenzoic acid ( 172 mg of $85 \%$ purity, 0.994 mmol ) in dichloromethane ( 15 mL ) was heated at the reflux temperature for 20 $h$. The cooled solution was washed with $5 \%$ sodium thiosulfate ( $2 \times 50$ mL ) and saturated sodium bicarbonate solutions ( 50 mL ) and water ( 50 mL ) prior to drying. Solvent evaporation left 220 mg of a viscous oil. MPLC purification on silica gel (elution with $5 \%$ ethyl acetate in hexanes) gave $150 \mathrm{mg}(54 \%)$ of epoxide 35 as a colorless solid: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 3.75(\mathrm{~s}, 6 \mathrm{H}), 3.00(\mathrm{~s}, 2 \mathrm{H}), 2.60(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 1.38(\mathrm{~s}, 3 \mathrm{H})$, $1.08(\mathrm{~s}, 3 \mathrm{H}), 1.9-0.7$ (series of m, 6 H ); ${ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) 165.61, 148.98, 70.82, 66.39, 57.59, 52.25, 40.48, 38.50, 27.91, 26.63, 25.24; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 318.1467 ; obsd 318.1475 .
$\boldsymbol{N}$-Phenylmaleimide Addition to $\mathbf{4 c}$. A solution of $\mathbf{4 c}(\mathbf{2 0 0} \mathrm{mg}, 1.27$ mmol ) and $N$-phenylmaleimide ( $1.10 \mathrm{~g}, 6.35 \mathrm{mmol}$ ) in benzene ( 5 mL ) was heated at reflux under a nitrogen atmosphere for 6 days. Direct MPLC purification of the reaction mixture on silica gel (elution with $10 \%$ ethyl acetate in petroleum ether) gave 50 mg ( $12 \%$ ) of an adduct ( A ) and 1 g of recovered dienophile. For $\mathrm{A}:{ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 7.5-7.2$ $(\mathrm{m}, 5 \mathrm{H}), 6.52(\mathrm{~m}, 2 \mathrm{H}), 3.45(\mathrm{~m}, 2 \mathrm{H}), 3.18(\mathrm{~s}, 2 \mathrm{H}), 2.3-2.1(\mathrm{~m}, 4 \mathrm{H})$, $1.22(\mathrm{~s}, 3 \mathrm{H}), 1.18(\mathrm{~s}, 3 \mathrm{H})$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$331. This material was directly hydrogenated.

Catalytic Hydrogenation of A. A solution of A ( $45 \mathrm{mg}, 0.136 \mathrm{mmol}$ ) in ethyl acetate ( 3 mL ) was hydrogenated over $5 \%$ palladium on charcoal $(5 \mathrm{mg})$ at atmospheric pressure for 20 min . Filtration and evaporation gave $40 \mathrm{mg}(89 \%)$ of a dihydro adduct. MPLC purification on silica gel (elution with $10 \%$ ethyl acetate in hexanes) afforded $36(35 \mathrm{mg})$ as a colorless solid: mp 193-193 ${ }^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right) \delta$ $7.58-7.15(\mathrm{~m}, 5 \mathrm{H}), 3.18(\mathrm{~s}, 2 \mathrm{H}), 3.05(\mathrm{~m}, 2 \mathrm{H}), 2.79(\mathrm{~s}, 2 \mathrm{H}), 1.85-0.85$ (m, 6 H$), 1.16(\mathrm{~s}, 3 \mathrm{H}), 1.141(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, CDCl ${ }_{3}$ ) 177.30, $154.14,132.39,129.19,128.46,125.84,55.69,50.73,49.62,42.96,25.83$, 21.31 ( 2 C ) (quaternary apical carbon not seen); mass spectrum, $m / e$ ( $\mathrm{M}^{+}$) calcd, 333.1729 ; obsd, 333.1736.
$\boldsymbol{N}$-Methyltriazolinedione Addition to $\mathbf{4 c}$. A solution of $\mathbf{4 c}$ ( 200 mg , 1.27 mmol ) in ethyl acetate ( 5 mL ) was treated at $-20^{\circ} \mathrm{C}$ under nitrogen with a solution of $N$-methyltriazolinedione ( $140 \mathrm{mg}, 1.27 \mathrm{mmol}$ ) in 5 mL of the same solvent. The reaction mixture was stirred at room temperature for 30 min and evaporated to give a $56: 44$ mixture ( ${ }^{1} \mathrm{H}$ NMR analysis) of adducts ( $340 \mathrm{mg}, 100 \%$ ). MPLC purification on silica gel (elution with $30 \%$ ethyl acetate in petroleum ether) destroyed one isomer and furnished the other ( $160 \mathrm{mg}, 47 \%$ ) as a substance (B) which slowly decomposes in air to a red oil: ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 6.52(\mathrm{t}, J=1.5 \mathrm{~Hz}$, $2 \mathrm{H}), 4.61$ (s, 2 H$), 3.60(\mathrm{~m}, 2 \mathrm{H}), 2.76(\mathrm{~s}, 3 \mathrm{H}), 2.31(\mathrm{~m}, 2 \mathrm{H}), 1.28$ $(\mathrm{s}, 3 \mathrm{H}), 1.10(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right) 159.58,159.39,142.88$, $74.86,71.08,61.85,48.60,25.15,21.36,21.2$; mass spectrum, $m / e\left(\mathbf{M}^{+}\right)$ calcd, 271.1321; obsd, 271.1330.

Catalytic Hydrogenation of B. A solution of $B(140 \mathrm{mg}, 0.517 \mathrm{mmol})$ in ethyl acetate ( 15 mL ) containing $5 \% \mathrm{Pd} / \mathrm{C}(50 \mathrm{mg})$ was hydrogenated as predescribed. There was obtained $130 \mathrm{mg}(93 \%)$ of 37 as a colorless solid: mp 168-170 ${ }^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 4.5(\mathrm{~s}, 2 \mathrm{H})$, $3.07(\mathrm{~m}, 2 \mathrm{H}), 2.87(\mathrm{~s}, 3 \mathrm{H}), 1.68-1.28(\mathrm{~m}, 4 \mathrm{H}), 1.30(\mathrm{~s}, 3 \mathrm{H}), 1.08(\mathrm{~s}$, $3 \mathrm{H}), 0.68$ (d of $\mathrm{t}, J=7.5$ and $1.5 \mathrm{~Hz}, 2 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $159.34,152.50,71.71,64.23,53.06,42.14,24.95$ (2 C), 21.89, 21.55; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 273.1477; obsd, 273.1485.

Anal. Calcd for $\mathrm{C}_{15} \mathrm{H}_{19} \mathrm{~N}_{3} \mathrm{O}_{2}$ : $\mathrm{C}, 65.91 ; \mathrm{H}, 7.01$. Found: $\mathrm{C}, 65.86$; H, 7.10 .
syn-1,2,3,4,5,6,7,8-Octahydro-5,9,9-trimethyl-1,4:5,8-dimethano-naphthalene-2,3-dicarboxylic Anhydride (38). A solution of 5 (200 mg, 1.15 mmol ) and maleic anhydride ( $113 \mathrm{mg}, 1.15 \mathrm{mmol}$ ) in benzene ( 2 mL ) was stirred under nitrogen at room temperature overnight. Evaporation of solvent left 306 mg ( $98 \%$ ) of a single adduct as a colorless solid: $\operatorname{mp} 188.0-188.5^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 3.48(\mathrm{br} \mathrm{s}, 1$ $\mathrm{H}), 3.42(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 2.89(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 2.59(\mathrm{~d}, J=3 \mathrm{~Hz}, 1 \mathrm{H}), 2.0-1.3$ (series of m, 6 H), $1.15(\mathrm{~s}, 3 \mathrm{H}), 0.82(\mathrm{~s}, 3 \mathrm{H}), 0.78(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $171.81,171.72,155.45,152.01,59.47,54.52,52.53,49.47$ (2 C), 48.21, 46.51, 45.39, 31.65, 24.86, 19.66, 18.30, 12.09; mass spectrum, $m / e\left(\mathrm{M}^{+}\right.$) calcd, 272.1412; obsd, 272.1419.

Anal. Calcd for $\mathrm{C}_{17} \mathrm{H}_{20} \mathrm{O}_{3}$ : $\mathrm{C}, 74.97 ; \mathrm{H}, 7.40$. Found: $\mathrm{C}, 75.11 ; \mathrm{H}$, 7.39 .
syn-1,2,3,4,5,6,7,8-Octahydro-5,9,9-trimethyl- $\boldsymbol{N}$-phenyl- $1,4: 5,8$-di-methanonaphthalene-2,3-dicarboximide (39). A solution of 5 ( 200 mg , 1.15 mmol ) and $N$-phenylmaleimide ( $200 \mathrm{mg}, 1.15 \mathrm{mmol}$ ) in benzene was stirred under nitrogen at room temperature overnight. Solvent evaporation left a single adduct ( $395 \mathrm{mg}, 99 \%$ ) which was purified by MPLC on silica gel (elution with $10 \%$ ethyl acetate in hexanes). There was obtained 340 mg ( $85 \%$ ) of 39 as colorless plates: mp 184.5-185.0 ${ }^{\circ} \mathrm{C}$ (from hexanes); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 7.6-7.15(\mathrm{~m}, 5 \mathrm{H}), 3.45$ (br s,
$1 \mathrm{H}), 3.40(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 2.73$ (br s, 2 H ), 2.58 (d, $J=3 \mathrm{~Hz}, 1 \mathrm{H}$ ), 2.1-1.5 (series of $\mathrm{m}, 6 \mathrm{H}), 1.18(\mathrm{~s}, 3 \mathrm{H}), 0.82(\mathrm{~s}, 3 \mathrm{H}), 0.76(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\mathrm{CDCl}_{3}$ ) $178.00(2 \mathrm{C}), 155.55(2 \mathrm{C}), 152.20,132.00,129.14$, 128.56, 127.78, 126.42, 59.42, 54.52, 52.67, 48.84 (2 C), 47.09, 45.34, $44.28,31.94,25.20,19.81,18.45,12.23$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right)$calcd, 347.1885; obsd, 347.1892 .

Anal. Calcd for $\mathrm{C}_{23} \mathrm{H}_{25} \mathrm{NO}_{2}: \mathrm{C}, 79.51 ; \mathrm{H}, 7.25$. Found: $\mathrm{C}, 79.51$; H, 7.29.
syn-Dimethyl $1,4,5,6,7,8$-Hexahydro-5,9,9-trimethyl-1,4:5,8-di-methanonaphthalene-2,3-dicarboxylate (40). A solution of 5 ( 200 mg , 1.15 mmol ) and freshly distilled dimethyl acetylenedicarboxylate ( 163 $\mathrm{mg}, 1.15 \mathrm{mmol}$ ) in chloroform ( 2 mL ) was stirred at room temperature under nitrogen for 2 h . Evaporation of solvent gave 360 mg of a yellow oil whose ${ }^{1} \mathrm{H}$ NMR spectrum showed one adduct to be present. MPLC purification afforded $220 \mathrm{mg}(61 \%)$ of 40 as a yellowish oil: ${ }^{1} \mathrm{H}$ NMR $(200 \mathrm{MHz})\left(\mathrm{CDCl}_{3}\right) \delta 3.757(\mathrm{~s}, 3 \mathrm{H}), 3.752(\mathrm{~s}, 3 \mathrm{H}), 2.56(\mathrm{br} \mathrm{d}, J=$ $3.7 \mathrm{~Hz}, 1 \mathrm{H}$ ), 2.50 (d of $\mathrm{t}, J=6.8$ and $1.9 \mathrm{~Hz}, 1 \mathrm{H}$ ), 2.22 (d of $\mathrm{t}, J=$ 6.8 and $1.25 \mathrm{~Hz}, 1 \mathrm{H}), 1.66-1.33(\mathrm{~m}, 4 \mathrm{H}), 1.11(\mathrm{~s}, 3 \mathrm{H}), 0.87(\mathrm{~s}, 3 \mathrm{H})$, $0.76(\mathrm{~s}, 3 \mathrm{H}), 0.55-0.41(\mathrm{~m}, 2 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (ppm, $\left.\mathrm{CDCl}_{3}\right)$ 166.18, $165.94,160.02,155.89,150.84,150.60,70.10,58.16,54.67,53.01,52.63$, 51.95 (2C), $50.83,29.32,22.33,19.42,18.01,12.14$; mass spectrum, $m / e$ ( $\mathrm{M}^{+}$) calcd, 316.1674; obsd, 316.1681.

Peracid Oxidation of $\mathbf{4 0}$. A solution of $\mathbf{4 0}(310 \mathrm{mg}, 0.981 \mathrm{mmol})$ and $m$-chloroperbenzoic acid ( 220 mg of $85 \%, 1.28 \mathrm{mmol}$ ) in dichloromethane ( 10 mL ) was heated at the reflux temperature for 22 h and worked up as previously described. The resulting colorless oil ( 400 mg ) was purified by MPLC on silica gel (elution with $10 \%$ ethyl acetate in petroleum ether) to give $160 \mathrm{mg}(48 \%)$ of $41 ;{ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 3.80$ $(\mathrm{s}, 6 \mathrm{H}), 3.37(\mathrm{~m}, 2 \mathrm{H}), 2.17(\mathrm{~m}, 2 \mathrm{H}), 1.9-1.0$ (series of m, 5 H$), 1.18$ $(\mathrm{s}, 3 \mathrm{H}), 1.10(\mathrm{~s}, 3 \mathrm{H}), 0.85(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $\mathrm{ppm}, \mathrm{CDCl}_{3}$ ) 165.26, $165.11,149.72,149.53,68.70,65.40,55.93,53.35,52.24,50.25,49.47$ (2C), $48.31,47.87,32.33,25.63,24.52,22.72,12.14$; mass spectrum, $m / e\left(\mathrm{M}^{+}\right) 332$.

Anal. Calcd for $\mathrm{C}_{19} \mathrm{H}_{24} \mathrm{O}_{5}: \mathrm{C}, 68.65 ; \mathrm{H}, 7.28$. Found: $\mathrm{C}, 68.60 ; \mathrm{H}$, 7.31 .

Acknowledgment. Financial support for the research conudcted at the Ohio State University was provided by the National Cancer Institute (Grant CA-12115). The work in Heidelberg was supported by the Fonds der Chemischen Industrie and BASF Aktiengesellschaft, Ludwigshafen.

    (12) Under these reaction conditions, 14 was isolated in $38 \%$ yield, accompanied by an unsymmetrical product ( $28 \%$ ) which has been tentatively formulated as i (see Experimental Section). Earlier work in this laboratory [Paquette, L. A.; Williams, R. V.; Carr, R. V. C.; Charumilind, P.; Blount, J. J. Org. Chem. 1982, 47, 4566] has shown that dienophiles of low reactivity are prone to add in similar fashion to the 1,5 -hydrogen-shifted isomer in the parent isodicyclopentadiene example. When 3a and phenyl vinyl sulfone were heated in dichloromethane at the reflux temperature for 36 h , the majority of the cycloaddition product was i ( $18 \%$ ); $68 \%$ of unreacted 3 a was also recovered. Under still more forcing conditions (toluene, reflux, 15 h , $50 \%$ consumption of diene occurred and i was formed to the extent of $21 \%$.

    striking. Thus, the apical carbon atoms of the anhydride ( 53.79 and 64.96 ppm ) compare closely to those of the imide ( 53.65 and 69.00 ppm ). Additionally, the methyl signals of 31 ( $\delta 1.0$ and $0.72)$ almost overlap those of $30(1.0$ and 0.82$)$. On this basis, the endo-anti configuration of 31 can be assigned with reasonable confidence. In the case of 32, recourse was again made to X-ray
    analysis (Figure 3) for the substantiation of structure
    In contrast to the above, DMAD reacted with $\mathbf{3 b}$ to give a mixture of two adducts in a 70:30 ratio. Identification of the major adduct as 33 was realized by means of ${ }^{13} \mathrm{C}$ NMR correlations (Table III) and peracid oxidation to give 35. Similarly, 34 clearly belongs to the anti-sesquinorbornadiene class on the basis of its
