Discrimination between Exo- and Endo-3,2-Methyl Shifts in Substituted 2-Norbornyl Cations on the (+)-Camphenilone Route to (–)-Albene

John E. Baldwin* and Timothy C. Barden

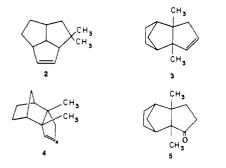

Contribution from the Department of Chemistry, University of Oregon, Eugene, Oregon 97403. Received May 2, 1983

Abstract: One key step in the synthetic route leading from (+)-camphenilone to (-)-albene, a chloro olefin annelation reaction, occurs with concomitant diminution of optical purity. An investigation of this reaction with a ¹³C,²H₂-labeled version of the chloro olefin accords with a recent reassignment of the absolute stereochemistry of (-)-albene as (1S, 2S, 6S, 7R)-2-endo,6endo-dimethyltricyclo[5.2.1.0^{2,6}]dec-3-ene and demonstrates that neither enantiomer of the rearrangement product depends on an endo-3,2-methyl shift in a substituted 2-norbornyl cationic intermediate.

(-)-Albene, a tricyclic olefin first isolated in 1962 from Petasites albus,¹ is now known to be the 1S, 2S, 6S, 7R enantiomer of 2endo,6-endo-dimethyltricyclo[5.2.1.0^{2,6}]dec-3-ene (1).²

Accurate structural, stereochemical, and absolute configurational assignments for this natural product have not been secured without difficulty. The first tentative structural proposal advanced in 1964,³ the dimethyltetrahydrotriquinacene formulation 2, was

abandoned in 1972 as additional evidence, including a chemical correlation between (-)-albene and (+)-camphene, was interpreted in terms of the correct structure (3) but the wrong stereochemistry (4).⁴ Structure 4 was supported in 1973 through independent work providing a synthesis of a degradation product, albanone (5; 2,6-dimethyltricyclo[5.2.1.0^{2,6}]decan-3-one), from camphenilone.⁵ The correct stereochemistry but the wrong absolute configuration were assigned in 1978 in work that included an X-ray crystallographic structure determination⁶ for the 4-phenylthio derivative of (\pm) -isoalbene ((\pm)-4), careful ¹³C NMR comparisons between albene and isoalbene,⁷ and a total synthesis of (-)-albene from (+)-camphenilone.^{8,9}

The correct structural and absolute stereochemical representation of (-)-albene has thus been notably elusive in spite of extensive efforts employing a variety of degradative and synthetic studies relating this comparatively small molecule to natural products of known stereochemistry and absolute configuration. Part of that chemistry, then, must be imperfectly understood and formulated according to invalid mechanistic assumptions.

^{*a*} $\mathbf{R} = CH_2CH_2CH = CCICH_3$, *C = ¹³C.

Consideration of this problem led us to speculate that the rearrangement of the chloro alcohol 6 in formic acid at reflux to the tricyclic ketone 7, a reaction used to secure (\pm) -albanone from

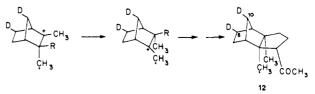

(±)-camphenilone⁵ and (-)-albene from (+)-camphenilone,^{8,9} may have been misconstrued twice and that (-)-albene might be the 1S,2S,6S,7R enantiomer 1. Conformation of the second supposition through a chemical correlation of methyl ketone 8 with β -santalene of known absolute stereochemistry² prompted this detailed investigation of the rearrangement $6 \rightarrow 7.10$

Lansbury and Boden utilized this chloro olefin annelation reaction in their synthesis of albanone (5). They found that only one isomer of product 7 was formed, and recognizing the wellknown preference of exo-3,2-methyl shifts over the corresponding endo shifts in norbornyl cations,¹¹ they concluded that 7 had exo-2,6-methyl groups.⁵ When Kreiser and Janitschke employed this reaction in their total synthesis of (-)-albene,^{8,9} they knew that the 2.6-methyl groups in the product 7 had the endo configuration: hence they formulated the reaction as one involving an endo-3,2-methyl shift.^{8,9} This interpretation, one presupposing the first example of an endo shift of an alkyl group in the Nametkin rearrangement,¹² led to an erroneous assignment of absolute stereochemistry for (-)-albene. Thus, neither simple rationale for the conversion $6 \rightarrow 7$, that is neither the exo-3,2-methyl shift postulate (leading to exo-2,6-methyl groups) nor the endo-3,2methyl shift alternative (leading to the mirror image of the observed product), is in agreement with experimental fact.

During our work that established the absolute stereochemistry of (-)-albene we determined the stereochemical course of the

Scheme III. Minor Stereochemical Path with Endo Shift^a

reaction $6 \rightarrow 7$ and discovered that it occurs with considerable racemization. The chiral precursor (-)-8 was found to give (+)-9 and (-)-9 in a 65:35 ratio.² One must explain, then, both the formation of (+)-9 as the dominant product and (-)-9 as a substantial coproduct.

The additional complications that must be considered are well-known but easily neglected: Wagner-Meerwein rearrangements and 6,2-hydride shifts.¹² A plausible explanation for the predominant stereochemical course of the annelation reaction, (-)-8 \rightarrow (+)-9, can be formulated in terms of an exo-3,2-methyl shift, Wagner-Meerwein rearrangements, and 6,2-hydride shifts. The minor pathway, (-)-8 \rightarrow (-)-9, could be rationalized through postulating an endo-3,2-methyl shift, but an alternative possibility was also considered reasonable. These various mechanistic descriptions of the conversion 8 \rightarrow 9 were tested with the aid of ¹³C- and ¹³C,²H₂-labeled substrates.

Experimental Design

With the aid of isotopically labeled but achiral substrates, the mechanistic concerns outlined above were tested as projected in Schemes I–III.

These three schemes predict that a ¹³C label present in starting alcohol in the exo C(3) methyl group will appear in both methyl groups of the product: the relative distribution of the ¹³C-label between C(6) and C(2) CH₃ should parallel the absolute stereochemical course of the reaction. Thus, the ¹³C label serves as surrogate for chirality: it provides an internal standard for the chiral course of the annelation reaction even though racemic substrate, not a chiral substrate, is employed. It was anticipated that the exact extent of racemization during the conversion $8 \rightarrow$ 9 might be quite sensitive to reaction conditions-Kreiser and Janitschke, one may now calculate,¹³ got a 58:42 instead of a 65:35 ratio of the enantiotopic ketones⁹-and thus some internal measure of that potential variable was required. The ¹³C label does *not* discriminate between Schemes II and III, the two alternatives leading to the byproduct which are to be tested.

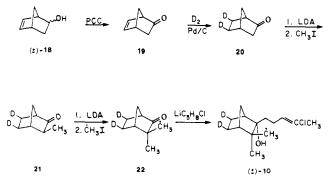

The deuterium labels in Scheme II appear at C(8) and C(10) of the product **12**, while Scheme III has them at C(8) and C(9)

Acta **1983**, 66, 627-632.

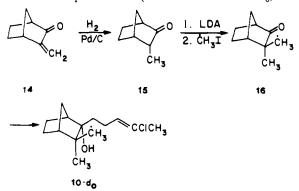

Scheme IV

of 13. That distinction, then, provides the basis for selecting between the two rationales for the reaction (-)-8 \rightarrow (-)-9. The possibility that *both* schemes II and III contribute to the formation of the minor product is also accommodated by the experimental design.

Results

Syntheses. Preliminary work with substrate labeled only with carbon-13 at the exo-3-methyl carbon tested the proposition that the majority of this label should appear at C(6) CH₃ = C(12) of the product and that the proportion of label C(12):C(11) should be about 65:35, the ratio of enantiomers formed from chiral unlabeled substrate (-)-8. The ¹³C-labeled alcohol was prepared from 3-methylene-2-norbornanone through catalytic reduction, alkylation¹⁴ with iodomethane-¹³C by way of the enolate anion prepared with lithium diisopropylamide in tetrahydrofuran and 1,3-dimethyl-3,4,5,6-tetrahydro-2(1H)-pyrimidinone (abbreviated DMPU: N,N'-dimethyl-N,N'-propylene urea)¹⁵ as a cosolvent, and treatment of the ¹³C-labeled camphenilone intermediate with 1-lithio-4-chloropent-3-ene¹⁶ ($14 \rightarrow 15 \rightarrow 16 \rightarrow 10-d_0$).

The literature reports numerous instances in which enolate anions of substituted 2-norbornanones undergo highly stereoselective alkylations from the exo face.¹⁷ High-field ¹H NMR of the camphenilone **16** confirmed that this selectively prevailed in the conversion **15** \rightarrow **16**. No ¹³CH₃ doublet was observed for the endo methyl group.

To secure the deuterium- and ${}^{13}C$ -labeled chloro olefin 10, the route of Scheme IV was employed. Commercial bicyclo-[2.2.1]hept-5-en-2-ol (18), a mixture of endo and exo isomers, was oxidized with pyridinium chlorochromate (PCC) to give bicyclo[2.2.1]hept-5-en-2-one (19).¹⁸ Reduction of the double

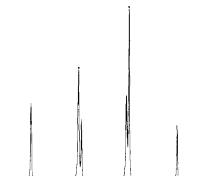

Figure 1. 360-MHz ¹H NMR spectrum of $C(11)H_3$ and $C(12)H_3$ in the product mixture 11 and 12 + 13 from chloro olefin 10. The upfield methyl is C(11); the dominant labeled methyl is $^{13}C(12)$.

bond with deuterium gas over 5% palladium on charcoal gave the 5-exo,6-exo-dideuterio ketone 20.¹⁹ Alkylation with iodomethane gave 5-exo,6-exo-dideuterio-3-exo-methylbicyclo[2.2.1]heptan-2-one (21). Repetition of the alkylation procedure with iodomethane-¹³C gave the desired camphenilone (22) having both deuterium and carbon-13 labels as depicted. From the same reaction mixture there was recovered some 5-exo,6-exo-dideuterio-3-endo-methylnorbornanone; mass spectroscopic analysis showed it to be 92% d_2 and 8% d_1 . The ¹³C incorporation of camphenilone 22 at the exo C(3) CH₃ carbon was estimated to be 96% by 360-MHz ¹H NMR spectroscopy. Again, no endo C(3) *CH₃ was detected. The labeled camphenilone 22 was treated with 1-lithio-4-chloropent-3-ene¹⁶ to give the alcohol (±)-10, the desired starting material (Scheme IV).

Annelation Reactions. The rearrangement $6 \rightarrow 7$ was conducted with the labeled substrates 10- d_0 and 10, making every effort to reproduce the experimental conditions recorded in the literature.^{5,9} Treating 10- d_0 or 10 for 2 h in 97–100% formic acid at reflux gave the tricyclic ¹³C and ¹³C,²H₂ methyl ketone products in 74–75% yield after Kugelrohr distillation. Final purifications before NMR spectroscopic analyses were done through preparative gas chromatography on a Carbowax 20M column.

¹H and ¹³C NMR Assignments. Although all of the ¹H and ¹³C NMR absorptions for ketone 7 had been assigned by earlier

workers,⁹ we felt obligated to reconsider these assignments afresh, for a proper interpretation of the spectra would obviously be highly sensitive to those assignments. We were substantially aided in this matter by having two labeled versions of 7 available.

The 100-MHz ¹H NMR assignments of 0.84 ppm to the C(12) methyl and 0.65 ppm to the C(11) methyl group⁹ were first verified by examining the effect of increasing portions of the shift reagent $Eu(hfbc)_3^{20}$ to an oxygen-free, C_6D_6 solution of methyl ketone (+)-9 remaining from previous work.² The proton resonance originally at 0.65 ppm moved downfield roughly 3.5 times faster than the 0.84 resonance in the presence of added shift reagent. Since the closer of the two angular methyl groups to the carbonyl moiety is expected to undergo the most rapid downfield shift with added europium shift reagent,²¹ the prior assignments are confirmed.

^a Reference 9. ^b ¹H decoupled. ^c ¹H coupled.

In the ${}^{13}C,{}^{2}H_{2}$ -labeled product from alcohol 10, ${}^{13}C-H$ spin-spin coupling gives absorptions on either side of the two ${}^{12}CH_{3}$ singlets (marked with * in Figure 1) with relative intensities indicative of the distribution of ${}^{13}C$ label at the two angular methyl positions.

The excess ¹³C originally incorporated in the exo methyl group of the precursor appears in the product ketone at both C(12) and C(11) in a 62:38 ratio, according to the ¹H NMR integrations. The ratio of ¹³C at C(12) and C(11) in the ketone derived from monolabeled alcohol **10-d**₀ (66:34) was similar to but not identical with that found for the ketone produced from **10**.

Careful comparisons of the proton-coupled and -decoupled ${}^{13}C$ NMR spectra of product ketones from 10 and 10- d_0 allowed unambiguous assignments to be made for all but two carbon atoms, C(8) and C(9), without recourse to any mechanistic assumptions regarding labels at certain carbons (Table I). Discrimination between C(8) vs. C(9) was made later, through interpretation of the proton-decoupled ${}^{13}C$ NMR spectrum of ${}^{13}C, {}^{2}H_{2}$ product after mechanistic issues had been resolved.

The majority of these assignments could be made quite straightforwardly by considering chemical shift, direct ${}^{13}C-H$ coupling, and in some cases the long-range ${}^{13}C-C-C-H$ coupling constants shown by ketone 11 and 12 + 13 (column 3, Table I). Several features of the spectrum of this mixture of ketones, however, do deserve explicit comment. In particular, the patterns observed for C(11) and C(12), C(1) and C(7), and C(10) in the ¹H-decoupled ¹³C NMR spectrum of the ¹³C,²H₂ ketone mixture require added explanation.

Long-range ${}^{13}C-C-C-H$ coupling, seen in C(10), C(11), and C(12), permitted individual assignments of these carbons as well as of C(5). Inspection of a molecular model indicates that a favorable dihedral angle exists for spin-spin coupling between C(10) and the endo hydrogens on C(8) and C(9), C(12) and both hydrogens on C(5), and C(11) and the single hydrogen on C(3).²² The carbon moxt extensively labeled, assigned as C(12) from ¹H NMR spectral analysis (Figure 2), does show the expected ¹³C-C-C-H₂ couplings (J = 5.9 Hz) to two hydrogens, while C(11) is split by a single ¹³C-C-C-H interaction (J = 4.9 Hz). Further confirmation for the C(12) and C(11) assignments comes from the quantitative agreement between C(12):C(11) peak height ratios in the proton-decoupled ¹³C spectra of ketones 11:12 + 13 (62:38) and of the corresponding mixture of ketones from 10- d_0 (64:36) with the ratio determined by ¹H NMR.

To the extent that in ketones 11 and 12 + 13 C(11) and C(12) are artificially enriched in ¹³C, direct ¹³C-¹³C coupling causes C(2) and C(6), respectively, to appear as doublets, centered around the singlets due to the uncoupled $C(2)^{-12}C(11)$ and $C(6)^{-12}C(12)$ moieties. The unequal intensities of the doublets and singlets must correspond with the established ¹³C distribution between C(11) and C(12); thus, the distinction between C(2) and C(6) can be made with confidence.

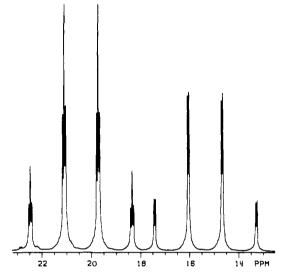

Figure 2. Long-range ${}^{13}C$ -C-C-H spin-spin coupling at C(12) (downfield methyl) and C(11) in the product mixture 11 and 12 + 13 from chloro olefin 10.

Figure 3. ¹H-decoupled ¹³C NMR spectrum of C(7) (downfield) and C(1) in the product mixture from chloro olefin 10. Each carbon has singlet peaks for environments with 0, 1, or 2 deuterium atoms on adjacent carbons.

Deuterium substitution at a carbon imparts an upfield shift of about 0.1 ppm to immediately adjacent carbons.^{23,24} The effect is additive: a carbon adjacent to two deuterium-bearing carbons is shifted upfield by about 0.2 ppm. The C(7) and C(1) signals are readily rationalized and assigned on this basis: Scheme I predicts that the most intense component of the C(1) resonance

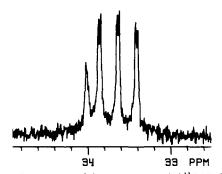

Figure 4. The C(10) region of the proton-decoupled ¹³C NMR spectrum of the product from chloro olefin 10; $J_{13}_{C-D} = 20$ Hz, $J_{13}_{CD-C-C-13}_{C(11,12)} = 2$ Hz.

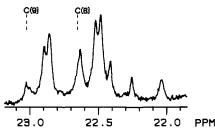

Figure 5. Observed natural abundance C(8) and C(9) proton-decoupled ¹³C NMR spectrum for ketones 11 + 12 from the chloro annelation of 10.

should be shifted upfield through interaction with two adjacent deuterium-bearing carbon atoms, C(9) and C(10), while C(7) is anticipated to have its larger signal component shifted upfield only by deuterium at C(10). This anticipation is independent of the balance between Schemes II and III. From these projections based on Scheme I and either Scheme II or III, the observed spectrum requires one to assign the more downfield of the two patterns shown in Figure 3 as due to C(7).

The proton-decoupled ¹³C lines for C(10)HD at 33.68 ppm show the triplet from $J_{^{13}C-D}$ and long-range coupling to ¹³C label at C(11) and C(12), as expected for structures **11** and **12**. The downfield line at 34.04 ppm from a minor C(10)H₂ component is consistent with expectations whether or not Scheme III contributes to the reaction, for **10** was not completely dideuterated and the intensity of the C(10)H₂ carbon resonance would be magnified by a larger NOE enhancement (Figure 4).

Of the three remaining CH_2 carbons, only C(4) should, according to Schemes I–III, never carry a deuterium label in the product mixture derived from 10; hence, C(4) is the carbon at 24.77 ppm, while C(8) and C(9), carbons that show the complications of partial deuterium substitution and partial deuteration on an adjacent carbon, have chemical shifts of 22.65 and 23.03 ppm (lit.⁹ values 22.49 and 22.88 ppm, respectively).

The ¹³C{¹H} spectrum for C(8) and C(9) in the mixture of ketones derived from **10** makes it clear that C(8) falls at higher field (Figure 5). The apparent doublets at about 22.5 and 22.9 ppm are due to long-range spin-spin coupling of C(8)H₂-C-C- 13 C(12) in product **11** and C(9)H₂-C-C- 13 C(11) in ketone **12** + **13**, while the two sets of triplets that overlap in part with the doublets are associated with C(8)HD centered at δ 22.26 and C(9)HD at δ 22.63. Schemes I and II give C(8) and C(9) coupled either with an attached deuterium or a ¹³C three bonds removed, but not with both. The relatively minor C(9) component near 23.0 ppm from C(9)H₂C(8)H₂, comparable to the downfield absorption in the C(10) ¹³C NMR spectrum (Figure 4), stems from incompletely deuterated substrate; the corresponding C(8) absorption is obscured by one line of the C(9)HD triplet centered at 22.63 ppm.

Spectral Interpretation. Assignments of chemical shifts to all carbons in ketone 7 have been made rigorously without presumption as to the relative importance of Schemes II and III, and the perturbations in the spectra of ketones derived from 10 and $10-d_0$ are in full agreement with the mechanistic schemes pres-

upposed. One must now attempt to discriminate between Schemes II and III.

The degree of upfield shift and relative intensities of the minor components of the ${}^{13}C{}^{1}H{}$ signals ascribed to C(7) and C(1) (Figure 3), the nearly complete monodeuteration of C(10) (Figure 4), and the pattern of absorptions observed for C(8) and C(9) (Figure 5) are all consistent with the presence of a significant amount of 12 in the product mixture. They provide no direct evidence for ketone 13.

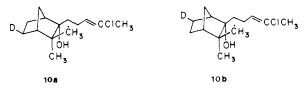

The C(9) ${}^{13}C{}^{1}H{}$ absorptions for ketone 13 would include a triplet of doublets (approximate J = 20, 3 Hz) centered at about 22.52 ppm, and C(8) of ketone 13 would show a triplet ($J \approx 20$ Hz) at 22.13 ppm. While some of the C(9) peaks might be obscured by absorptions of 11 and 12, the entire C(8) triplet of 13 would be clearly observable. No such peaks can be seen (Figure 5).

What error limits may be ascribed to the conclusion that 13 is not a component of the reaction mixture? How large a contribution of the Scheme III mechanism might be present and yet remain undetected? Clearly the signal/noise ratio obtained in the ¹³C NMR experiment itself must be considered limiting if one attempts to use Figure 5 to establish these limits. Even so, as little as 3% should be observable since the relative noise level is low.

Two additional estimates can be obtained by consideration of the relative peak intensities of the ¹³C{¹H} resonances associated with C(7) and C(1). The first assumes the same nuclear Overhauser enhancement (NOE) for both C(7) and C(1) and considers only dideuterio-labeled material. No complications then arise from incomplete deuteration of the starting material or from potential loss of deuterium during the rearrangement. The second method takes monodeuterated product into consideration and assumes that the rearrangement proceeds without loss of deuterium.¹²

In the first approach, the relative intensities of the most upfield ${}^{13}C{}^{1}H{}$ resonances for C(1) and C(7), that is those affected by *two* adjacent CD units, are compared. If only Schemes I and II apply, in the 62:38 ratio as determined by the disposition of the ${}^{13}C{}$ label, the C(1):C(7) intensity ratio should be 62:38 = 1.6. Should Scheme III contribute as little as 3% overall, this ratio is predicted to increase to 1.8. The observed ratio is 1.5 ± 0.1, just less than or equal to the value predicted by theory. Any contribution from Scheme III only makes the ratio larger. The NOE of the two signals would have to differ by a factor of 1.2 in the requisite sense before a 3% contribution would be masked.

Alternatively, in the second approach, one could compare the relative intensities of the two ${}^{13}C{}^{11}H{}C(7)$ resonances shifted upfield by one and two adjacent CD moieties. While the C- $(1)(CD)_1:C(1)(CD)_2$ ratio remains constant regardless of the contribution of Scheme III, the corresponding ratio for C(7) is predicted to be extremely sensitive to even small amounts of Scheme III; here, no assumption of relative NOE values is needed since both peaks are, in fact, from the same carbon. One may stipulate that the 8% of d₁ material known to be present in alcohol **10** is represented by a 4% contribution each of alcohols **10a** and **10b**. If there is no contribution from Scheme III, the C(7)(C-

D)₁:C(7)(CD)₂ ratio should be 1.78. The corresponding ratio if 3% and 5% of Scheme III were to contribute is predicted to be 2.02 and 2.20, respectively. The observed ratio of 1.8 ± 0.1 is in quantitative agreement with theory if Scheme III is completely nonparticipatory in the overall rearrangement process.

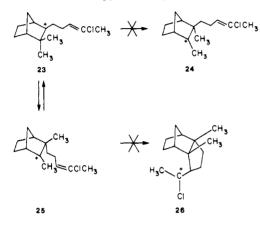

Discussion

The chloro olefin annelation reaction $6 \rightarrow 7$, as followed in detail for the labeled analogues $10 \rightarrow 11 + 12$, occurs without any contribution from the endo-3,2-methyl shift formalized in Scheme III. The labeling results are consistent with Schemes I and II,

Methyl Shifts in Norbornyl Cations

involving Wagner-Meerwein rearrangements, exo-3,2-methyl and -alkyl shifts, and endo-6,2-hydride shifts.

The central findings of this study accord well with results obtained for the rearrangement of longifolene to isolongifolene²⁵ and that proposed for the acid-catalyzed interconversion of copacamphene and sativene.²⁶ The fundamental structural reasons that favor multistep processes in Schemes I and II, pathways that totally eschew endo-3,2-methyl shifts, probably do not involve substantial σ -participation in the 2-norbornyl cations generated. Although the experimental and theoretical evidence favoring the bridged or nonclassical structural formulation for the parent 2-norbornyl cation appears overwhelmingly convincing,27 tertiary 2-norbornyl cations, such as 2-methyl-2-norbornyl and camphenehydro cations, are classical, unbridged intermediates.¹² Nevertheless, the detailed structure of putative intermediate 23 does not allow a kinetically competitive endo-3,2-methyl shift to afford products derived from 24, and intermediate 25 does not permit reaction from the endo approach to give 26.

A likely rationale for these striking stereochemical propensities of classical tertiary 2-norbornyl cations may be found in the suggestions of Schleyer:²⁸ torsional effects in such cations may well be of sufficient magnitude to control stereochemical options so decisively.

Conclusions

The labeling strategy adopted for this mechanistic investigation permitted an efficient resolution of the issue posed by earlier reports: the rearrangement of chloro olefin 6 to both isomers of ketone 7 occurs through well-precedented carbonium ion paths, without intrusion of an endo-3,2-methyl migration in a substituted norbornyl cation. The recent revision of assignment for the absolute stereochemistry of (-)-albene² was confirmed, and the intimate relationships between mechanistic understandings of intermediates and reactions and practical applications were once again exemplified. Only reactions of securely known structural and absolute stereochemical propensities provide sure grounds for deducing structures and absolute stereochemical assignments through chemical correlations between known and unknown compounds.

Experimental Section

Unless noted otherwise, reactions were conducted under a nitrogen atmosphere with magnetic stirring in flame-dried or oven-dried (130 °C, overnight) glassware; organic solutions of crude products were dried over magnesium sulfate, filtered, and concentrated by rotary evaporation. Commercial n-butyllithium in hexanes and tert-butyllithium in pentane (Aldrich) were standardized with diphenylacetic acid.²⁹ Dichloromethane and 1,3-dimethyl-3,4,5,6-tetrahydro-2(1H)-pyrimidinone (DMPU)¹⁵ were dried over activated 4-Å molecular sieves. Diisopropylamine was distilled from KOH pellets and stored over activated 3-Å molecular sieves. Tetrahydrofuran (THF) was dried over sodium and benzophenone, and diethyl ether was dried over lithium aluminum hydride; each was distilled under a positive nitrogen pressure directly into reaction vessels as required. Vapor-phase chromatography (VPC) was performed on a Varian Aerograph A90-P3. Gas chromatography column A was a 6.4 mm × 1.22 m aluminum column packed with 20% Carbowax 20M on 60/80 mesh Chromasorb W-AWDMCS; column B was a 2.5-m long version of column A. Analytical samples of 16, 22, 10, 10-d₀, and 11 + 12 were obtained on these columns before any spectra were recorded. ¹H NMR, ²H NMR, and ¹³C NMR spectra were recorded in CDCl₃ solutions; chemical shift values reported are relative to one of the following internal standards: Me₄Si at 0.0 ppm (¹H), CHCl₃ at 7.27 ppm (¹H), CDCl₃ at 7.27 ppm (²H), CDCl₃ at 77.00 ppm (¹³C). Unless noted ¹H NMR spectra were obtained at 100 MHz on a Varian XL-100 instrument; all other NMR spectra were obtained on a Nicolet NT-360 instrument operating in the Fourier transform mode. Infrared spectra were obtained on a Sargent-Welch 3-200 infrared spectrophotometer with CDCl₁ solutions except where noted. Mass spectra were determined on either a CEC21-110B or a Hewlett-Packard HP5930M mass spectrometer. Melting points were obtained in sealed capillary tubes and are uncorrected. The obvious physical properties of all compounds described below agreed with those reported in the literature for the unlabeled analogues.

Bicyclo[2.2.1]hept-5-en-2-one (19). Pyridinium chlorochromate (29.51 g, 0.137 mol) was suspended in 150 mL of CH_2Cl_2 , the suspension was stirred at room temperature for 15 min, and then the flask was cooled in ice; 5-norbornen-2-ol (7:3 mixture of endo and exo alcohols, 9.53 g, 0.086 mol) in CH_2Cl_2 (10 mL) was added quickly. The ice bath was removed and the reaction mixture was stirred for 5 h with occasional water-bath cooling to keep the reaction mixture from boiling. Ether (300 mL) was added, the reaction mixture was stirred another 1 h, and the ethereal mixture was filtered through Florisil. The black gum still in the reaction vessel was washed with more ether (2×100 mL); these extracts were filtered through the same Florisil. Concentration of the filtrate by careful rotary evaporation followed by distillation at 16 torr gave 4.73 g (50%) of **19** as a colorless liquid: bp 54–56 °C (16 torr) [lit.¹⁸ bp 69–70 °C (25 torr)]: NMR δ 6.56 (dd, J = 3, 6 Hz, 1 H), 3.18 (m, 1 H), 3.00 (m, 1 H), 1.82–2.3 (c, 4 H).

5-exo,6-exo-Dideuteriobicyclo[2.2.1]heptan-2-one (20).30 Keto olefin 19 (3.32 g, 30.7 mmol) was dissolved in ether (100 mL) in a 250-mL Morton flask, the system was flushed with nitrogen, and 5% palladium on charcoal (0.30 g) was added. A 50-mL burette was filled with water and inverted into a large beaker partially filled with water such that the lower end was below the surface of the water. The burette was repeatedly charged with deuterium gas from a lecture bottle (Matheson; reported 99.5%), and the liquid was allowed to flow from the top of the burette into the bottom of the vigorously stirred reaction mixture through a long needle until the theoretical amount of deuterium had been used. The catalyst was removed by gravity filtration and the ether was distilled through a Vigreux column. Ketone 20 (2.92 g, 85%) was obtained as a white solid by adding pentane to the distillation residue and slowly cooling the resultant solution to -78 °C: mp 94-96 °C (lit.³⁰ mp 90-93 °C); NMR δ 2.52-2.80 (br m, 2 H), 1.20-2.20 (c, 6 H); IR (CHCl₃) 3005, 2950, 2880, 2200, 2170, 1735, 1405, 960 cm⁻¹

5-exo.6-exo-Dideuterio-exo-3-methylbicyclo[2.2.1]heptan-2-one (21). A solution of diisopropylamine (5.0 mL, 35.3 mmol) in THF (70 mL) and DMPU¹⁵ (35 mL) was cooled to -35 to -40 °C in a dry ice/acetonitrile bath. A solution of *n*-butyllithium (1.4 M, 21.4 mL, 30.0 mmol) was added dropwise in 5 min; the reaction mixture was stirred for 30 min, the cooling bath was replaced with a dry ice/acetone bath at -78 °C, and then ketone **20** (2.82 g, 25.1 mmol) in THF (3 mL) was added in 20 min to the solution of lithium diisopropylamide (LDA). The reaction mixture

⁽³¹⁾ Both C(3) epimers of 3-methylnorbornanone were recover from the reaction mitture. The VPC-purified endo isomer (*endo*-21) was analyzed by mass spectrometry at a low-ionizing voltage; unlabeled ketone 15 served as a reference standard. The deuterium incorporation in *endo*-21 was 92% d_2 and 8% d_1 (at "10 eV").

was stirred at -78 °C for another 1.5 h, and then methyl iodide (2.1 mL, 33.7 mmol) was added dropwise; the solution was allowed to warm to room temperature over 11 h. Ether (200 mL) was added to the orange product mixture; the ethereal solution was washed with water (7 × 150 mL) and brine (100 mL), dried, and carefully concentrated by rotary evaporation at 10 °C. Purification through medium-pressure liquid chromatography on silica gel with ethyl acetate/hexanes (3:17) as eluent followed by careful removal of solvents by distillation gave 1.42 g (45%) of pure ketone **21** as a colorless liquid: NMR δ 2.52 (br s, 1 H), 2.30 (br s, 1 H), 1.20–1.96 (c, 5 H), 1.05 (d, J = 8 Hz, 3 H); IR (CHCl₃) 3005, 2960, 2880, 2205, 2190, 2170, 1735, 1470, 1450, 965, 955, 905 cm⁻¹.

5-exo, 6-exo-Dideuterio-3-endo-methyl-3-exo-(methyl-13C)bicyclo-[2.2.1]heptan-2-one (22). A solution of LDA in THF (10 mL) and DMPU (5 mL) at -45 to -50 °C was prepared as before from diisopropylamine (0.85 mL, 6.0 mmol) and n-butyllithium (1.6 M in hexanes, 3.5 mL, 5.6 mmol). At -78 °C, the neat ketone 21 (0.65 g, 5.1 mmol) was added, and the reaction mixture was stirred at this temperature for 2.3 h. The enolate thus generated was quenched by addition of iodomethane-13C (99 atm % reported, Merck; 0.19 mL, 3.0 mmol) at -78 °C, followed by another 7 h of stirring. Wet ether (50 mL) was added; the reaction mixture was allowed to warm to room temperature and was washed successively with water ($6 \times 20 \text{ mL}$) and brine (30 mL). After being dried and filtered, the ethereal solution was carefully concentrated by rotary evaporation and purified by medium-pressure liquid chromatography on silica gel with ethyl acetate/hexanes (1:9) giving 0.23 g (55%) of the ¹³C-labeled camphenilone 22 as a white solid:³¹ ¹H NMR (360 MHz) δ 2.57 (br s, 1 H), 2.23 (br s, 1 H), 1.98 (br d, 1 H), 1.72 (br d, 1 H), 1.40-1.50 (m, 2 H), 1.06 (s, exo ¹²CH₃, 0.12 H), 1.06 (d, J = 128 Hz, exo ¹³CH₃, 2.88 H), 1.02 (s, endo CH₃, 0.12 H), 1.02 (d, J = 6 Hz, endo CH₃, 2.88 H); ²H NMR (55 MHz) δ 1.82 (br d, 1.0 D), 1.60 (br d, 1.0 D); IR (CHCl₃) 3005, 2960, 2880, 2205, 2180, 1735, 1380, 1360, 905 cm⁻¹

2-[2-Chloroprop-2-en-5-yl]-5-exo,6-exo-dideuterio-3-endo-methyl-3 $exo-(methyl-1^{3}C)$ bicyclo[2.2.1]heptan-2-ol ((±)-10). 1-Iodo-4-chloropent-3-ene¹⁶ (0.75 g, 3.2 mmol) in ether (5 mL) and under an argon atmosphere was cooled to -78 °C. A 1.8 M solution of tert-butyllithium (2.6 mL, 4.7 mmol) was added dropwise and the resultant solution at -78 °C was stirred 20 min. Ketone 22 (0.17 g, 1.2 mmol) in ether (0.5 mL) was added dropwise; the reaction mixture was stirred for 30 min at -78 °C and then for 16 h at room temperature. Brine (5 mL) was added, and the two phases were well mixed and separated. The aqueous phase was extracted with ether (10 mL), acidified with 10% HCl, and extracted with more ether $(2 \times 10 \text{ mL})$. The combined ethereal phases were dried, filtered, and concentrated; Kugelrohr distillation of the residue gave 0.23 g (76%) of alcohol (±)-10 as a viscous, colorless oil, collected from 75 to 85 °C (oven temperature) at 0.03 torr: NMR & 5.38-5.70 (m, 1 H), 2.00-2.20 (c, 2 H), 2.09 (m, 3 H), 0.80-1.90 (c, 8 H), 0.97 (d, J = 128Hz, ~ 3 H), 0.92 (d, J = 5 Hz, ~ 3 H); IR (CHCl₃) 3600, 3450, 3010, 2990, 2950, 2880, 2430, 2390, 2180, 1660, 1470, 1445, 1430, 1380, 1360 cm⁻¹

3-endo -Acety]-2-endo, 6-endo -dimethyltricyclo[5.2.1.02,6]decane- ${}^{2}\text{H}_{2}$, ${}^{13}\text{CH}_{3}$ 11 + 12. Chloro alcohol 10 (0.23 g, 0.92 mmol) was dissolved in 97-100% formic acid (1.3 mL), and the mixture was heated at reflux for 2 h. The dark reaction solution was then cooled in ice, 25% aqueous NaOH (5.5 mL) was added, and the resultant solution was extracted with CH_2Cl_2 (4 × 15 mL). Kugelrohr distillation of the residue from the combined, dried, filtered, and concentrated organic phases gave 0.14 g (75%) of ketone 11 + 12 as a colorless liquid, collected from 65 to 75 °C (oven temperature) at 0.3–0.4 torr. The last traces of impurities were removed by VPC on column A: NMR (360 MHz) δ 2.57 (dd, J = 12,6Hz, 1 H), 2.22 (br s, 1 H), 2.12 (s, 3 H), 1.25-1.85 (c, 9 H), 0.84 (s, 12 CH₃ at C(12), 1.36 H), 0.84 (d, J = 126 Hz, 13 C at C(12), 1.72 H), 0.67 (s, ¹²C at C(11), 1.84 H), 0.67 (d, J = 126 Hz, ¹³CH₃ at C(11), 1.08 H); ²H NMR (55 MHz) δ 1.31 (br s, skewed upfield from deuterium at C(8) and C(9), 1.00 D), 1.00 (br s, symmetric, deuterium at C(10), 1.00 D); ¹³C NMR (90 MHz) see column 1, Table I; IR (CHCl₃) 2990, 2950, 2870, 2430, 2400, 2200, 2170, 1695, 1385, 1370, 1355 cm⁻¹

endo-3-Methylbicyclo[2.2.1]heptan-2-one (15). 3-Methylenebicyclo-[2.2.1]heptan-2-one (7.02 g, 55.7 mmol) was dissolved in absolute ethanol (100 mL) in a 250-mL Parr pressure bottle. A slurry of 5% palladium

on charcoal (0.65 g) in ethanol (10 mL) was added, and the bottle was placed in the shaking apparatus. The bottle was then thrice evacuated (aspirator) and filled with hydrogen. After the final evacuation the hydrogen pressure was adjusted to 4 atm and the bottle was shaken for 1.5 h, until the theoretical amount of hydrogen was consumed. The catalyst was removed by gravity filtration, and the ethanol was distilled at atmospheric pressure. Pure methyl ketone **15** (4.92 g, 71%) was obtained as a colorless liquid by distillation at 16 torr: bo 68 °C; NMR δ 2.42–2.66 (c, 2 H), 1.20–2.20 (c, 7 H), 1.01 (d, J = 7 Hz, 3 H); IR 2970, 2870, 1730, 1450, 1295, 1170, 1095, 1030 cm⁻¹.

3-endo-Methyl-3-exo-(methyl-13C)bicyclo[2.2.1]heptan-2-one (16). A solution of LDA was prepared at -50 °C as previously described from diisopropylamine (0.65 mL, 4.5 mmol) and a 1.3 M solution of n-butyllithium (3.5 mL, 4.5 mmol) in a mixture of THF (10 mL) and DMPU (5 mL). The cooling bath was then replaced with dry ice/acetone at -78 °C, and neat ketone 15 (0.57 g, 4.6 mmol) was added dropwise to the reaction mixture. After the reaction mixture was stirred for another 3 h, jodomethane- ^{13}C (0.27 mL, 4.3 mmol) was added to guench the enolate; stirring was continued for 2.5 h at -78 °C and for 11.5 h at room temperature. The orange solution was diluted with ether (50 mL), washed with water $(6 \times 20 \text{ mL})$ and brine (50 mL), dried, filtered, and carefully concentrated to 2 mL by rotary evaporation. Final purification by medium-pressure liquid chromatography on silica gel was effected with ethyl acetate/hexanes (1:9) giving 0.29 g (48%) of pure ¹³C-labeled ketone **16**: NMR δ 2.50-2.62 (m, 1 H), 2.23 (br s, 1 H), 1.22-2.10 (c, 6 H), 1.06 (d, J = 128 Hz, exo ¹³CH₃, 3 H), 1.03 (d, J = 5 Hz, endo ¹²CH₃, 3 H); IR 2960, 2920, 2870, 1735, 1485, 1465, 1380, 1355, 1290, 1155, 1100, 1055 cm⁻¹

2-[2-Chloroprop-2-en-5-yl]-3-*endo*-methyl-3-exo-(methyl- ${}^{13}C$)bicyclo-[2.2.1]heptan-2-ol (10- d_0). 1-Lithio-4-chloropent-2-ene was generated under argon at -78 °C as before by combination of 1-iodo-4-chloropent-2-ene (0.49 g, 2.1 mmol) and a 1.8 M solution of *tert*-butyllithium (1.9 mL, 3.4 mmol) in ether (5 mL). Camphenilone 16 (0.20 g, 1.4 mmol) was added, and the solution was stirred at -78 °C for 30 min and then at room temperature for 17 h. Brine (5 mL) was added, the two layers were separated, and after acidification the aqueous layer was extracted with additional ether (3 × 10 mL). The combined ethereal phases were dried and concentrated by rotary evaporation. Kugelrohr distillation of the residue at 0.15 torr gave 0.30 g (86%) of pure alcohol 10- d_0 , collected as a viscous liquid from 70 to 90 °C (oven temperature)). NMR δ 5.38-5.70 (m, 1 H), 2.00-2.20 (c, 2 H), 2.09 (m, 3 H)). 0.80-1.90 (c, 10 H), 0.97 (d, J = 26 Hz, exo 13 CH₃, 3 H), 0.93 (d, J =5 Hz, endo 12 CH₃, 3 H); IR 3600, 3465, 2950, 2870, 1660, 1465, 1450, 1430, 1380, 1360, 1355 cm⁻¹.

3-endo-Acetyl-2-endo,6-endo-dimethyltricyclo[5.2.1.0^{2.6}]decane-¹³CH₃. A mixture of chloro alcohol 10- d_0 (0.26 g, 1.1 mmol) and 97-100% formic acid (1.5 mL) was heated at reflux for 2 h and then cooled in ice; the acid was neutralized by addition of 25% aqueous NaOH (6.4 mL). Extraction was performed with CH₂Cl₂ (4 × 10 mL), and the combined organic phases were dried and concentrated by rotary evaporation. Pure ketone 11 + 12- d_0 , a viscous oil, was obtained from the dark residue by Kugelrohr distillation; 0.16 g (74%) was collected between 60 and 80 °C (oven temperature) and at 0.4 torr: NMR δ 2.68 (dd, J = 10, 6 Hz, 1 H), 2.12 (br s, 1 H), 2.14 (s, 3 H), 1.02-1.94 (c, 11 H), 0.86 (s, ¹²CH₃ at C(12), 1.29 H), 0.86 (d, J = 126 Hz, ¹³CH₃ at C(12), 1.97 H), 0.67 (s, ¹²CH₃ at C(11), 1.67 H), 0.67 (d, J = 126 Hz, ¹³CH₃ at C(11), 1.06 H); ¹³C NMR (90 MHz) see column 2, Table I; IR 2940, 2870, 1645, 1470, 1385, 1365, 1355, 1235, 1170 cm⁻¹.
