#### Abstract

A series of closo icosahedral rhodacarboranes bearing substituents at carbon has been synthesized by the reaction of $\left[\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ with the correspondingly C -substituted nido-carborane anions: [closo-1-R-2-R'-3,3- $\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2-$ $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] from [nido-7-R-8- $\left.\mathrm{R}^{\prime}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]^{-}$where $\mathrm{R}=\mathrm{R}^{\prime}=\mathrm{H} ; \mathrm{R}=\mathrm{R}^{\prime}=\mathrm{D} ; \mathrm{R}=\mathrm{H}$ and $\mathrm{R}^{\prime}=\mathrm{Ph}$, Me , and $n-\mathrm{Bu}$; [closo-1-R-2,2- $\left(\mathrm{PPh}_{3}\right)_{2}-2-\mathrm{H}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] from [nido-7-R-7,9- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$where $\mathrm{R}=\mathrm{H}, \mathrm{Ph}$, and Me; and [closo-2,2-$\left(\mathrm{PPh}_{3}\right)_{2}-2-\mathrm{H}-2,1,12-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] from [nido-2,9-C2 $\left.\mathrm{C}_{9} \mathrm{H}_{12}\right]^{\circ}$. These closo icosahedral rhodacarboranes are catalytically active in alkene isomerization and hydrogenation reactions, among others. The $\mathrm{B}-\mathrm{D}-\mathrm{B}$ bridge deuterated $\left[\text { nido- } 7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11} \mathrm{D}\right]^{-}$ gave [closo-3,3-( $\left.\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{D}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] when reacted with [ $\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}$ ], establishing the regiospecific transfer of BHB hydrogen to $\mathrm{Rh}-\mathrm{H}$ in the synthesis reaction. The complex [closo-1-n- $\mathrm{Bu}-3,3-\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] is apparently transformed to [closo-8-n-Bu-2,2-( $\left.\mathrm{PPh}_{3}\right)_{2}-2-\mathrm{H}-2,1,8-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] by a polytopal rearrangement under mild conditions. The optically active catalyst [ $d$-closo-1-Me-3,3-( $\left.\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] was employed to hydrogenate ethyl $\alpha$-phenylacrylate to give ethyl $\alpha$-phenylpropionate in $3 \%$ enantiomeric excess. In the absence of hydrogen this chiral catalyst reacted with certain esters of the acrylic type to yield alkyl chelates in which the alkene function of the ester had undergone migratory insertion into the $\mathrm{Rh}-\mathrm{H}$ and the ester carbonyi oxygen became bound to Rh . One of these chelates, derived from the $d$-catalyst and $n$-butyl acrylate, was characterized crystallographically. The compound crystallizes in the space group $P 2_{1} 2_{1} 2_{1}$ with unit cell parameters $a=24.578$ (5) $\AA, b=12.543$ (2) $\AA$, and $c=10.377$ (2) $\AA$, four molecules per unit cell. The structure was solved by conventional heavy-atom methods and refined to a final value of $R=0.069, R_{\mathrm{w}}=0.080$ (3159 reflections). The absolute configuration of the $d$-catalyst and the $\left[1-n i d o-7-\mathrm{Me}-7,8-\mathrm{B}_{9} \mathrm{C}_{2} \mathrm{H}_{11}\right]^{-}$, from which it was derived, was thus established. Reaction of the unsubstituted compounds [closo-3,3- $\mathrm{L}_{2}-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] and [closo-2,2- $\mathrm{L}_{2}-2-\mathrm{H}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] ( $\mathrm{L}=\mathrm{PPh}_{3}$ ) with more basic phosphines gave the corresponding $\mathrm{L}_{2}$ compounds with $\mathrm{L}=\mathrm{PEt}_{3}, \mathrm{PMe}_{2} \mathrm{Ph}$, and for the $3,1,2$-isomer, $\mathrm{L}_{2}=$ $\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2} \mathrm{PPh}_{2}$. Reaction of the unsubstituted $3,1,2$-isomer ( $\mathrm{L}=\mathrm{PPh}_{3}$ ) with HCl in $\mathrm{CHCl}_{3}$ gave [closo-3,3- $\left(\mathrm{PPh}_{3}\right)_{2}-3-$ $\left.\mathrm{Cl}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$. The analogous chloro compound in which $\mathrm{L}=\mathrm{PMe}_{2} \mathrm{Ph}$ was prepared by the reaction of the $\mathrm{Rh}-\mathrm{H}$ species with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Reaction of [closo-2,2-( $\left.\mathrm{PPh}_{3}\right)_{2}-2-\mathrm{H}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] with $\mathrm{HCl} / \mathrm{CHCl}_{3}$ produced the coordinatively unsaturated 16 -electron species [closo-2- $\mathrm{PPh}_{3}-2-\mathrm{Cl}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ]. This complex reacted with CO and other ligands to produce coordinatively saturated adducts. A crystallographic study of the 16 -electron 2,1,7-chloride was carried out. This compound crystallizes in the monoclinic system $P 2_{1} / n, a=13.840$ (5) $\AA, b=17.000$ (7) $\AA, c=13.771$ (6) $\AA$, and $\beta=118.98$ (2) ${ }^{\circ}$, four molecules of complex and four molecules of benzene per unit cell. The structure was determined by conventional heavy-atom methods and refined to a final value of $R=0.039$ (4173 reflections), $R_{w}=0.055$. Although the electron deficiency seems to be metal centered, the molecule suffers little polyhedral distortion. The orientation of the $\mathrm{Cl}-\mathrm{Rh}^{2}-\mathrm{PPh}_{3}$ plane is in strict agreement with the stereochemical predictions based upon the HOMO-LUMO treatment of Mingos. Reaction of $\left[7-\mathrm{R}-8-\mathrm{R}^{\prime}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]^{-}\left(\mathrm{R}=\mathrm{R}^{\prime}=\mathrm{Me} ; \mathrm{R}=\mathrm{H}, \mathrm{R}^{\prime}=\mathrm{Ph} ; \mathrm{R}=\mathrm{H}, \mathrm{R}^{\prime}=\mathrm{Me}\right)$ with $\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}^{2}, \mathrm{PPh}_{3}$, and aqueous $\mathrm{HBF}_{4}$ produced the previously reported, but incorrectly formulated, species [closo-1-R-2-R'-3-PPh $-8-\mathrm{PPh}_{3}-3-\mathrm{Cl}-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] in which one $\mathrm{PPh}_{3}$ at Rh had formally interchanged with the terminal H at $\mathrm{B}(8)$ in a hypothetical [closo-1-R-2-R'-3,3-$\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{Cl}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] intermediate.

In 1974 we became intrigued by the possibility of discovering suitably constituted metallacarboranes that would activate small molecules and serve as homogeneous catalysts. The well-known structural diversity of metallacarboranes coupled with their normally high kinetic stabilities suggested that catalysts based upon this relatively new chemistry might find utility. Shortly after embarking upon this endeavor we developed a general synthesis route to metallacarboranes having dissociable phosphine ligands, namely the reaction of low-valent, coordinatively unsaturated transition-metal phosphine complexes with nido- or arachnocarboranes containing acidic hydrogen atoms. ${ }^{3,4}$ We had previously reported ${ }^{4}$ the synthesis of two catalytically active isomers

[^0]of the complex [closo- $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}(\mathrm{H}) \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (Ia and IIa) by this means utilizing the reaction of [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ with [nido-$\left.7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$or [nido-7,9- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$, respectively. These complexes may be formally considered to arise by oxidative addition of the $\mathrm{B}-\mathrm{H}-\mathrm{B}$ bridge system of the respective [nido $\left.-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$ anions to an unsaturated $\mathrm{Rh}(\mathrm{I})$ atom accompanied by $\eta^{5}$ bonding of the resulting $\mathrm{Rh}($ III ) moiety to the open carborane cage face. The structure of the $3,1,2$-isomer, $\left[\right.$ closo-3,3- $\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2$ $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{~B}_{11}$ ] (Ia), is shown in Figure $1 .{ }^{5}$ Complex Ia has been shown to be an active catalyst precursor for the homogeneous hydrogenation and isomerization of alkenes, ${ }^{4}$.6a the hydrosilylation

[^1]

Figure 1. Molecular structure of [closo-3,3- $\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2$ $\left.\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$. Thermal ellipsoids, except for phenyl carbon atoms, are shown at the $50 \%$ probability level. Hydrogen atoms, with the exception of the terminal hydride, have been omitted for clarity.
of ketones, ${ }^{4}$ the hydrogenolysis of alkenyl acetates, ${ }^{6 \mathrm{~b}}$ and the exchange of terminal B-H bonds with deuterium gas. ${ }^{6,4}$, The ease of preparation, the versatility, and the stability of this formally 18 -electron Rh (III) complex make it an extremely attractive homogeneous catalyst precursor and thus prompted us to explore the reactivity of the various isomers of Ia and their derivatives. An analogous complex, [closo- $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}(\mathrm{H})\left(\mathrm{SB}_{10} \mathrm{H}_{10}\right)$ ], has also been described. ${ }^{6 e}$ We have reported ${ }^{7 \mathrm{am}, \mathrm{b}}$ the preparation and catalytic activity of a polymer-bound analogue of Ia, [closo-$3,3-\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-4$-(polystyrylmethyl)-3,1,2- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ], which can be recovered from catalytic hdyrogenation experiments by filtration. A similar polymer-bound catalyst was subsequently prepared by Rudolph et al. ${ }^{8}$ In conjunction with our catalytic studies, we have examined the reactivity of the metal hydride present in Ia with strong acids. Reaction of Ia with $\mathrm{H}_{2} \mathrm{SO}_{4}$ or $\mathrm{HNO}_{3}$ affords the versatile metallacarborane reagents [closo$\left.\left(\mathrm{PPh}_{3}\right)_{2}\left(\mathrm{HSO}_{4}\right) \mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{9}$ and [closo- $\left(\mathrm{PPh}_{3}\right)\left(\mathrm{NO}_{3}\right)$ $\left.\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]{ }^{10}$ respectively.

In order to further explore this unique chemistry, we have prepared a variety of complexes analogous to Ia using C-substituted carborane cages, various phosphine ligands, and the 2,9 -isomer of [nido- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$to generate the previously unreported $2,1,12$-isomer of Ia, namely III. In the case of a mono-C-substituted or asymmetrically $\mathrm{C}, \mathrm{C}^{\prime}$-disubstituted 1,2 $\mathrm{CRC}^{\prime} \mathrm{R}^{\prime} \mathrm{B}_{10} \mathrm{H}_{10}$ carborane, base degradation removes one of two chemically equivalent boron atoms ${ }^{11}$ to generate a racemic mixture of chiral [nido-7,8-CRC'R $\left.{ }^{\prime} \mathrm{B}_{9} \mathrm{H}_{10}\right]^{-}$anions which can be resolved by the use of optically active cations. ${ }^{12}$ It has thus proved possible to synthesize and study the optically active rhodacarborane catalyst precursor [d-closo- $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}(\mathrm{H}) \mathrm{CMeC}^{\prime} \mathrm{HB}_{9} \mathrm{H}_{9}$ ] derived from optically pure (l-nido-7-Me-7,8-C $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$. Although preliminary results of the attempted asymmetry hydrogenation of prochiral

alkenes with this catalyst precursor gave alkane products in relatively low optical yields, these studies resulted in the isolation of several chelated alkyl rhodacarborane complexes, one of which has been characterized by an X-ray diffraction study described here.

We have recently reported ${ }^{13}$ dynamic multinuclear FTNMR studies of hindered rotation of the metal vertex present in icosahedral metallacarboranes with respect to the pentagonal bonding face of the carborane ligand. In addition, we have discussed ${ }^{14}$ the facile carborane cage exchange reaction which has provided a means of transferring the [ $\left.\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}\right]$ fragment from one carborane cage to another in a single, clean reaction. Both of these studies involved complexes described in this contribution. We have also shown that subtle modifications of these compounds can result in drastic changes in their gross structures and reactivities. ${ }^{15,16}$

[^3]We now wish to report a detailed study of the synthesis of a series of icosahedral closo-bis(phosphine)hydridorhodacarboranes and to discuss their varied reactivity with esters of alkyl- and arylacrylic acids and chlorinating agents. The synthesis and reactivity of the iridium analogues of several of the complexes described will be reported in a subsequent paper. ${ }^{17}$

## Results and Discussion

Synthesis of Icosahedral Hydridobis(phosphine)rhodacarboranes. Complexes Ia-f, IIa-c, and III [see Figures 2-4] were prepared by heating the corresponding [nido-CRC' $\left.\mathrm{R}^{\prime} \mathrm{B}_{9} \mathrm{H}_{10}\right]^{-}$anions with [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ in absolute ethanol at the reflux temperature. The yellow to orange [closo- $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}(\mathrm{H}) \mathrm{CRC}^{\prime} \mathrm{R}^{\prime} \mathrm{B}_{9} \mathrm{H}_{9}$ ] products precipitated from these reactions after several hours. These compounds were stable to air in the solid state but decomposed to a significant extent in solutions exposed to the atmosphere. Several of these compounds were prepared by stirring the two reactants in anhydrous methanol at room temperature for ca. 24 $h$. This procedure minimized the formation of undesired side products (e.g., $\left[\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{RhCl}\right]_{2}$ and trans- $\left.\left[\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}(\mathrm{CO}) \mathrm{Cl}\right]\right)$ which were obtained from prolonged heating of $\left[\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ in ethanol. We have also prepared optically active Ie, henceforth referred to as $\mathrm{Ie}^{*}$, from the corresponding enantiomerically pure carborane anion [l-nido-7- $\left.\mathrm{CH}_{3}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$(vide infra). ${ }^{18}$

The carbon-deuterated analogue of Ia, namely Ib , has proven useful as a means of monitoring cage exchange reactions. ${ }^{14}$ The carbon-deuterated carborane anion was reacted with [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ in ethanol at the reflux temperature to give Ib , which had no detectable carborane $\mathrm{C}-\mathrm{H}$ resonance in the ${ }^{1} \mathrm{H}$ NMR spectrum. No loss of carborane C-D was observed after heating in ethanol for 1 week. We have also synthesized ${ }^{19}$ the Rh-D analogue of Ia, namely Ic, by briefly heating the bridgedeuterated carborane anion ${ }^{20}$ with $\left[\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ in ethanol at the reflux temperature. Thus, the source of the rhodium hydride ligand of Ia and related species is indeed the bridging $\mathrm{B}-\mathrm{H}-\mathrm{B}$ of the incoming carborane monoanion.

Complexes Ig and Ih, [closo-3,3-( $\mathrm{L}_{2}$ )-3-H-3,1,2- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] ( $\mathrm{L}=\mathrm{PEt}_{3}$ and $\mathrm{PMe}_{2} \mathrm{Ph}$, respectively), can be prepared by the reaction of the corresponding $\left\{\mathrm{L}_{3} \mathrm{Rh}^{+} \mathrm{BF}_{4}\right\}$ salt ${ }^{21}$ and [nido-7,8$\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-}$in methanol. A more convenient route, which has also been used to prepare the isomeric complexes [closo-2,2-( $\mathrm{L}_{2}$ )-2-$\left.\mathrm{H}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ ( $\mathrm{L}=\mathrm{PEt}_{3}, \mathrm{PMe}_{2} \mathrm{Ph}$ ) (IId and IIe, respectively), as well as the chelated complex [closo-3,3$\left(\mathrm{PPh}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{PPh}_{2}\right)$-3-H-3,1,2- $\left.\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ (Ii), involved the reaction of the corresponding triphenylphosphine complexes with an excess of the appropriate phosphine in tetrahydrofuran (THF). The 3,1,2-complexes (Id, Ie, Ih, and Ii) were very sensitive to air in solution, darkening rapidly. NMR studies $\left({ }^{1} \mathrm{H},{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}\right.$, and ${ }^{11} \mathrm{~B}$ ) ${ }^{22}$ suggest that complexes Id-h decompose to dimeric phosphinerhodacarboranes similar in nature to the purple complex prepared from Ia and characterized by NMR and X-ray crystallography. ${ }^{23}$ Complex [closo-1-n-Bu-3,3- $\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2-$ $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (If), when heated to reflux in THF for 3 days in the presence of excess $\mathrm{PPh}_{3}$, appeared to undergo a polytopal rearrangement. NMR spectroscopy ( ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right)$, and $\left.{ }^{11} \mathrm{~B}\right)$ suggested

[^4]

Figure 5. Polytopal rearrangement proposed for thermal conversion of If to $\mathrm{lf}^{\prime}$.
the structure of the rearranged complex If' to be analogous to that of [closo-1-Me-2,2-( $\left.\mathrm{PEt}_{3}\right)_{2}-2 \cdot \mathrm{H}-8-\mathrm{Ph}-2,1,8-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] whose structure has been determined by X-ray crystallography. ${ }^{16}$ Complex If would then be formulated as [closo-8-n-Bu-2,2-$\left.\left(\mathrm{PPh}_{3}\right)_{2}-2-\mathrm{H}-2,1,8-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ as shown in Figure 5.
Preparation of Optically Active [d-closo-1-Me-3,3- $\left(\mathrm{PPh}_{3}\right)_{2}-3-$ $\left.\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]\left(\mathrm{Ie}^{*}\right)$ and Chelated Alkyl Complexes. Resolution of racemic [nido-7-Me-7,8- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] was achieved by use of the $l-N, N, N$-trimethyl ( $\alpha$-phenylethyl)ammonium cation as the resolving agent in ethanol solvent. After 18 recrystallizations, optically pure $\left[l-\mathrm{Me}_{3} \mathrm{NCH}(\mathrm{Me})(\mathrm{Ph})\right]^{+}\left(l \text {-nido- } 7-\mathrm{Me}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$ was obtained ( $[\alpha]^{25}{ }_{579}-16.8^{\circ}$ ). The trimethylammonium salt was then prepared by ion exchange chromatography $\left([\alpha]^{25}{ }_{579}-5.9^{\circ}\right)$. Reaction of this salt with [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ in ethanol at room temperature produced optically active $\left[d\right.$-closo- $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}-$ $\left.(\mathrm{H})\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \mathrm{Me}\right)\right]$ ( $\mathrm{Ie}^{*}$ ) after recrystallization from THF/ethanol $\left([\alpha]^{25}{ }_{579}+5.3^{\circ}\right)$.
In order to explore the potential of $\mathrm{Ie}^{*}$ as a catalyst precursor for the asymmetric hydrogenation of prochiral alkenes, ethyl $\alpha$-phenylacrylate was selected for study. Ethyl $\alpha$-phenylacrylate appeared to be a favorable choice because (a) isomerization could not compete with hydrogenation and (b) Ia was an effective catalyst for the hydrogenation of acrylate esters. ${ }^{6 a}$ When a THF solution of $\mathrm{Ie}^{*}$ containing ethyl $\alpha$-phenylacrylate $(6.45 \mathrm{mM}$ in catalyst, 0.10 M in alkene) was stirred at $25^{\circ} \mathrm{C}$ under 1 atm of $\mathrm{H}_{2}$, no $\mathrm{H}_{2}$ uptake was observed over 21 h . The experiment was repeated in an autoclave under 100 atm of $\mathrm{H}_{2}$ at $25^{\circ} \mathrm{C}$. Although this resulted in complete reduction of the alkene to ethyl $\alpha$-phenylpropionate, the measured optical rotation indicated an enantiomeric excess of only $3 \%\left([\alpha]^{25}{ }_{\mathrm{D}}+1.9^{\circ}\right.$ (lit. $\left.{ }^{24} 59.6^{\circ}\right)$ ). It was not possible to recover the catalyst precursor since it had been converted to a blue rhodacarborane species (vide infra). Although Ie did not catalyze the reduction of ethyl $\alpha$-phenylacrylate under ambient conditions, it was found to be an active catalyst for the hydrogenation of $n$-butyl acrylate ( $25^{\circ} \mathrm{C}, 1 \mathrm{~atm} \mathrm{H}_{2}$ ) with an initial rate of ca. $5.8 \times 10^{-2} \mathrm{~mol} \mathrm{H}_{2} \mathrm{~mol}^{-1} \mathrm{Rh} \mathrm{s}^{-1}$. This result suggests that once the acrylate is coordinated to the rhodium, the sterically demanding $\alpha$-phenyl group of the prochiral substrate, compared with the H atom of the unsubstituted acrylate, renders $\mathrm{H}_{2}$ coordination unfavorable, and thus no hydrogenation is observed under mild conditions. However, it was noticed that upon injection of ethyl $\alpha$-phenylacrylate into the orange solution of the catalyst precursor the color rapidly turned a deeper red-orange. The addition of ethanol formed red-orange crystals of IVa which were isolated. The same behavior was also observed in the absence of $\mathrm{H}_{2}$. Complexes IVb and IVc were similarly prepared by reaction of Ie with $n$-butyl acrylate and methyl methacrylate, respectively. Furthermore, when [exo-nido- $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \mathrm{Me}_{2}\right)$ ] ${ }^{15}$ was reacted with methyl methacrylate in THF at room temperature, a red-orange product (IVd) was isolated which appeared to be a nalogous to IVa-c on the basis of analytical and spectroscopic data.
Elemental analyses of compounds IVa-c were consistent with products formed by the insertion of the acrylate or substituted acrylate ester $\mathrm{C}=\mathrm{C}$ into the $\mathrm{Rh}-\mathrm{H}$ bond of Ie accompanied by loss of a $\mathrm{PPh}_{3}$ molecule. The product (IVd) derived from [exo-

[^5]

Figure 6. Molecular structure of [closo-1-Me-3,3- $\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{C}(\mathrm{O}) \mathrm{OBu}-\right.$ $3-\mathrm{PPh}_{3}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (IVb). Thermal ellipsoids are shown at the $50 \%$ probability level. Hydrogen atoms have been omitted for clarity.
nido- $\left.\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \mathrm{Me}_{2}\right)\right]^{15}$ was formulated in an identical manner. Furthermore, IR spectra contained no evidence for the presence of $\mathrm{Rh}-\mathrm{H}$ or $\mathrm{B}-\mathrm{H}-\mathrm{B}$ (bridge) bonds, but each compound exhibited an intense band in the region of $1615 \mathrm{~cm}^{-1}$, attributed to $\nu_{\mathrm{C}=0}$, fully $100 \mathrm{~cm}^{-1}$ lower in frequency than the carbonyl stretching frequency in the free acrylate ester. This result suggested that the ester carbonyl oxygen atom present in the substituted alkyl group attached to rhodium was chelated to rhodium, as well. This coordination of the ester carbonyl moiety to rhodium with weakening of the $\mathrm{C}=\mathrm{O}$ bond should lower the stretching frequency of the ester carbonyl group with respect to free ester, as observed. A similar shift in $\nu_{\mathrm{C}}=0$ has been reported ${ }^{25}$ for a series of chelated alkenyl carboxylic esters derived from the reaction of $\left[\mathrm{H}_{2} \mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{4}\right]$ with a variety of acrylate esters ( $\mathrm{RuCH}=$ CHCOOR). The formation of a closo $\sigma$-bonded alkyl complex from [exo-nido- $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \mathrm{Me}_{2}\right)$ ] is explained ${ }^{15}$ by a facile exo-nido-closo equilibrium that has been demonstrated to exist in solution.

In order to confirm the structural hypothesis presented above, an X-ray diffraction study of IVb was undertaken. The molecular structure is shown in Figure 6, and selected distances and angles are given in Table I. As predicted, the organic ligand is coordinated to the rhodium atom both through the oxygen atom of the ester carbonyl group and through an alkyl linkage. This results in distorted octahedral geometry about the 18 -electron Rh (III) atom in which the cage is assumed to occupy three coordination sites. The $C(4)-C(5)$ and $C(5)-C(6)$ distances within the puckered 5 -membered metallacycle are both $1.54 \AA$, typical of $\mathrm{C}-\mathrm{C}$ single bonds. The $\mathrm{Rh}-\mathrm{C}$ distance ( 2.10 (1) $\AA$ ) is very similar to other $\mathrm{Rh}(\mathrm{III})-\mathrm{C}$ bond lengths; for example, in $\left[R h_{2} I_{2}\right.$ $\left.\left(\mathrm{SMe}_{2}\right)_{3} \mathrm{Me}_{4}\right]$ and in $\left[\mathrm{RhCl}_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)_{2}\left\{\mathrm{P}\left(o-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}\right)_{2}(o-\right.\right.$ $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2}$ ) \}] these distances are $2.08{ }^{26}$ and 2.083 (16) $\AA$, ${ }^{27}$ respectively. Rhodium-oxygen bond lengths vary widely, and the distance found here ( 2.185 (8) $\AA$ ) is only slightly longer than $\mathrm{Rh}-\mathrm{O}$ distances in various Rh(III) complexes, for example 2.098 (4) $\AA$ in $\left[\mathrm{RhCl}(\mathrm{PhCONCS})_{2}\left(\mathrm{PPh}_{3}\right)_{2} \cdot \mathrm{Et}_{2} \mathrm{O}\right]^{28}$ and in two recently characterized $\mathrm{Rh}(\mathrm{I})$ chelated cinnamate complexes (2.113 (5) and $2.185(5) \AA) .{ }^{29,30}$ The C(6)-O(1) distance of 1.24 (2) $\AA$ is not

[^7]significantly shorter than $\mathrm{C}-\mathrm{O}$ distances (1.254 (12) and 1.248 (8) $\AA)^{25,29}$ in analogous chelated complexes.

In addition to the mode of bonding seen in complex IVb the X-ray diffraction study of this complex establishes the absolute configuration of [l-nido-7-Me-7,8- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$as well as the $d$ - $\mathrm{Ie} *$ and IVb species derived from it. The fact that IVb contains a chiral carborane cage and a chiral rhodium center provides the possibility of obtaining IVb from $d$ - Ie * in two diastereomerically related configurations. That IVb was apparently present as a pure diastereomer proves that the configuration of the rhodium center in crystalline IVb is rigorously controlled by the steric requirements of the carborane ligand. It is interesting to note that in none of the complexes IVa-d are diastereomers observed by variabletemperature ${ }^{1} \mathrm{H}$ or ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy (vide infra). Thus, either the two sets of resonances are very close together in all cases or the barrier to interconversion of the diastereomers is quite low or both. It seems likely that interconversion might easily occur at the rhodium center by either dissociation of $\mathrm{PPh}_{3}$ or cleavage of the rhodium-oxygen bond. However, the free energy difference between the two possible diastereomeric species may truly be large and subject to the stereochemical control fo the carborane ligand.

Although the complexes IVa-d are stable indefinitely in air in the solid state, they rapidly decompose under argon in solution at room temperature, presumably due to dissociation of the organic ligand via $\beta$-elimination to form $\mathrm{Rh}-\mathrm{H}$ in the absence of $\mathrm{PPh}_{3}$.

Figure 7. Schematic representation of chelate complexes $1 \mathrm{Va}-\mathrm{d}$ and labeling of protons for ${ }^{1} \mathrm{H}$ NMR assignment.

Recrystallization of the chelates could only be carried out in the presence of a large excess of acrylate ester in order to avoid total decomposition of these complexes.

The ${ }^{1} \mathrm{H}$ NMR spectra of the chelates (see Figure 7 and Experimental Section) were complex, but were assigned by means of a series of homonuclear and phosphorus decoupling experiments carried out at $-33^{\circ} \mathrm{C}$ to avoid decomposition. Spectra acquired rapidly at room temperature had shown there to be no observable dependence on temperature. In addition, the spectra indicated that the structure of the complexes in solution must be very similar to that found for IVb in the solid state.

In all four complexes the resonance due to $\mathrm{H}_{\mathrm{a}}$ appears as a triplet ( ${ }^{2} J_{\mathrm{H}_{\mathrm{a}}-\mathrm{H}_{b}}={ }^{3} J_{\mathrm{H}_{a}-\mathrm{H}_{c}}$ ) whereas $\mathrm{H}_{\mathrm{b}}$ appears as a multiplet. The additional splitting is due to coupling to phosphorus, although the magnitude of the coupling could not be determined due to the complex nature of the resonances observed. $\mathrm{H}_{\mathrm{b}}$ resonates ca. 2 ppm upfield from $\mathrm{H}_{a}$, in keeping with observed chemical shift differences between methylenic protons in a variety of cyclic complexes. ${ }^{31}$ Coupling of either $\mathrm{H}_{\mathrm{a}}$ or $\mathrm{H}_{\mathrm{b}}$ to Rh was not resolved and must presumably be less than $2 \mathrm{~Hz} . \mathrm{H}_{\mathrm{c}}$ also appears as a multiplet in complexes $\mathrm{IVb}-\mathrm{d}$, coupled to $\mathrm{H}_{\mathrm{a}}, \mathrm{H}_{\mathrm{b}}$, and $\mathrm{H}_{\mathrm{d}}$. In complex IVa the resonance is significantly shifted to low field due to the neighboring Ph group. The resonance of the Me protons of the ester group in IVc and IVd is a sharp singlet as expected, but in IVa and IVb the methylene protons are magnetically nonequivalent since no symmetry element exists between them. In IVa each proton gives rise to two overlapping quartets and in IVb two sets of overlapping triplets result ( ${ }^{2} J_{\mathrm{H}_{\mathrm{t}}-\mathrm{H}_{f}}=11,{ }^{3} J_{\mathrm{H}_{\mathrm{e} \cdot} \cdot \mathrm{H}_{\mathrm{g}}}$ $=6 \mathrm{~Hz}$ in both cases).

An interesting feature of the spectra is the fact that in IVa-c the carborane $\mathrm{C}-\mathrm{Me}$ protons appear as a doublet which collapses to a singlet upon phosphorus decoupling ( ${ }^{4} J_{\mathrm{P}-\mathrm{H}}=2 \mathrm{~Hz}$ ). Examination of the structure of IVb indicates that $\mathrm{C}(1)-\mathrm{Me}$ group to be approximately trans to the P atom bonded to Rh whereas the $C(2)$ atom is cis to the $P$ atom. In the case of IVd only one of the carborane $\mathrm{C}-\mathrm{Me}$ groups shows coupling of its protons to phosphorus, which suggests that $\mathrm{P}-\mathrm{H}$ coupling is only observed when the Me group is bonded to the trans C -atom, in agreement

[^8]

Figure 8. Schematic representation of structures of chloro complexes $V$, Vla-f, and Vlla-c.

Figure 9. Molecular structure of [closo-2-Cl-2,1,7-RhC2 $\left.\mathrm{B}_{9} \mathrm{H}_{11}\right] \cdot \mathrm{C}_{6} \mathrm{H}_{6}$ (V). Thermal ellipsoids are shown at the $50 \%$ probability level. Hydrogen atoms have been omitted for clarity.
with the well-documented observation that trans coupling to phosphorus is significantly greater than cis coupling. ${ }^{32}$ The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of the complexes exhibited one doublet ( $J_{\mathrm{Rh}-\mathrm{P}}=$ 139 Hz ) in all cases and were temperature independent. The ${ }^{11} \mathrm{~B}$ NMR spectra were generally broad and uninformative.

Synthesis and Reactions of $\mathbf{R h}-\mathbf{C l}$ Derivatives: Structure of [closo-2- $\mathrm{PPh}_{3}-\mathbf{2 - C l}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11} \cdot \mathrm{C}_{6} \mathrm{H}_{6}$ ] (V). Attempted recrystallization of the $\mathrm{PMe}_{2} \mathrm{Ph}$ complex Ih from dichloromethane gave the chloro complex [closo-3,3-( $\left.\mathrm{PMe}_{2} \mathrm{Ph}\right)_{2}-3-\mathrm{Cl}-3,1,2-$ $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (Ik) in quantitative yield. We have been able to prepare the previously reported ${ }^{33} \mathrm{PPh}_{3}$ analogue [closo-3,3-$\left.\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{Cl}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ ( Ij ) in $73 \%$ yield by heating Ia in $\mathrm{CHCl}_{3}$ /aqueous HCl . An attempt to prepare the isomeric [closo-2,2-( $\left.\mathrm{PPh}_{3}\right)_{2}-2-\mathrm{Cl}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] complex by a similar procedure yielded instead the 16 -electron closo-mono(triphenylphosphine) chloro complex (V) (see Figure 8). Skeletal electron counting formalisms ${ }^{34}$ suggest that $V$ contains 12 electron pairs for skeletal bonding and should exhibit a hyper-closo ${ }^{35}$ geometry. Recent modifications of these rules by Nishimura ${ }^{36}$ suggest that the effective atomic number of the metal center must

[^9]

Figure 10. View of the RhPCl moiety and the $\mathrm{C}_{2} \mathrm{~B}_{3}$ face coordinated to rhodium in V.
be considered in order to determine the geometry of the polyhedron. This approach suggested that $V$ with formally 16 -electron Rh (III) might possess 13 skeletal electron pairs available for cage bonding and thus exhibit closo geometry. In order to resolve the question of polyhedral geometry an X-ray diffraction study of V was undertaken.

Selected interatomic distances and angles in V are listed in Table II.

The structure of $V$, shown in Figure 9 together with the numbering system employed, unambiguously shows no distortion of the 12 -vertex polyhedron. A different perspective illustrated in Figure 10 shows negligible movement of the metal center from the center of the bonding face of the cage.

The rotational conformation assumed by the $\mathrm{P}-\mathrm{Rh}-\mathrm{Cl}$ plane with respect to the bonding face of the carborane cage is the same as that predicted by Mingos ${ }^{37}$ for an isoelectronic osmium complex (vide infra). For the hypothetical model compound [closo-2,2-( $\left.\mathrm{PH}_{3}\right)_{2}-2,1,7-\mathrm{PtC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ], the HOMO-LUMO interaction between the hybrid $(x z)-5 \mathrm{e}_{1}(x)$ orbitals favors conformer B and

the filled antibonding $5 \mathrm{e}_{1}(y)-(y z)^{*}$ orbital in B is lower in energy than the corresponding $5 \mathrm{e}_{1}(x)-(y z)^{*}$ orbital present in conformer A. It was also suggested that "compounds such as [closo-2,2-$\left.\left(\mathrm{PR}_{3}\right)_{2}-2,1,7-\mathrm{OsC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ may prove to be thermodynamically more stable than the corresponding platinum compounds" ${ }^{37}$ because the loss of two electrons eliminates the antibonding interaction described above. It was inferred that the loss of two electrons should give rise to conformer A based on an examination of the HOMO-LUMO interaction diagram. Indeed, complex V , which is isoelectronic with [closo- $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{OsC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ], exists as conformer A in the solid state. Consequently, it can be concluded that the electron deficiency of V is metal centered and that the molecule suffers little polyhedral distortion. This contrasts with the recently published X-ray crystallographic study of [hyper-closo-2,3-( $\left.\mathrm{CH}_{3}\right)_{2}$-6-( $\left.\mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}\right)-6,2,3-$ $\left.\mathrm{RuC}_{2} \mathrm{~B}_{7} \mathrm{H}_{7}\right]^{35}$ in which the electronic unsaturation is delocalized over the polyhedral framework, resulting in a distorted triangulated closed polyhedral structure. At this point, the factors that determine whether electronic unsaturation will remain metal centered or be delocalized over the polyhedral framework are not clearly understood.

Compound V showed a wide range of reactivity with typical two-electron donors, demonstrating the unsaturation at the rhodium vertex (see Figure $8 ;{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR data are presented in Table III). When a $\mathrm{CDCl}_{3}$ solution of V was treated with CO , an immediate color change from dark red to light yellow occurred, giving the CO adduct VIa. The CO ligand could be easily removed by flushing the yellow solution with argon, thus regenerating V .

$a^{\text {a }}$ limated standard deviations in the least significant figure are given in parentheses. ${ }^{b}$ listimated standard deviations are not given for member of rigid groups. The normal to the plane defined by $\mathrm{P}-\mathrm{Rh}-\mathrm{Cl}$ makes an angle of $79.32^{\circ}$ with the normal to the least-squares plane through the $C_{2} B_{3}$ belt (i.e., the bonding face) of the carborane cage.

Addition of nitrogen donor solvents such as pyridine or acetonitrile to $\mathrm{CDCl}_{3}$ solutions of V gave orange solutions of compounds VIb and VIc, respectively. Addition of $\mathrm{PPh}_{3}$ (2.2 equiv) to $\mathrm{CDCl}_{3}$ solutions of V showed only a slight color change and gave broad resonances in ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR experiments at $27^{\circ} \mathrm{C}$, suggesting a rapid exchange process. Cooling the sample to $-23^{\circ} \mathrm{C}$ gave sharp resonances corresponding to the saturated bis(triphenylphosphine) complex (VId). Smaller and more basic phosphines such as $\mathrm{PEt}_{3}$ or $\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2} \mathrm{PPh}_{2}$ (DPPE) displaced the $\mathrm{PPh}_{3}$ ligand of V , yielding the saturated bis(phosphine) complexes VIe and V1f, respectively. Compound V did not react with unsaturated organic ligands such as ethylene, cycloocta-1,5-diene, or ethynylbenzene under ambient conditions in ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR experiments. A series of ${ }^{31} P\left\{{ }^{1} \mathrm{H}\right\}$ NMR competition experiments demonstrated the order of coordination of the ligands to be DPPE, $\mathrm{PEt}_{3} \gg \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}>\mathrm{CO}$ $>\mathrm{CH}_{3} \mathrm{CN}>\mathrm{PPh}_{3} \gg$ unsaturated organic ligands.

Formation of Rhodium Hydrido Chlorides Accompanied by Migration of Triphenylphosphine from Rh to $B$. When the $C$ phenyl complex (Id) was recrystallized slowly by layering heptane over a dichloromethane solution of the complex, traces of bright orange crystalline material (VIIa) were found mixed with the Id which crystallized as large red-brown blocks. This orange material was mechanically separated from Id and a series of spectra ob-

tained which showed it to be a hydridophosphinerhodacarborane complex distinct from Id. This complex was also observed in sealed NMR samples of Id in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ after a period of several months. The spectra of the orange complex were identical with those of a complex described ${ }^{38}$ as " $3-\mathrm{PPh}_{3}-3^{\prime}$ - $\left(\mathrm{Ph}_{2} \mathrm{P}-1-\mathrm{C}_{6} \mathrm{H}_{4}-\right)-3-\mathrm{H}-3,1,2-$ $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$. It had been suggested ${ }^{38}$ that one of the phosphine ligands was bound to the carborane cage through the carborane $C$-phenyl substituent. Complexes with similar modes of bonding had been proposed ${ }^{38}$ for the $C, C^{\prime}$-dimethyl and $C$-methyl, $C^{\prime}$-ethyl derivatives that had been prepared ${ }^{38}$ by heating a mixture of [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right], \mathrm{PPh}_{3}$, aqueous $\mathrm{HBF}_{4}$, and the appropriate carborane anion in ethanol. We have repeated this synthesis using the nido-7-phenyl-, -7-methyl-, and -7,8-dimethyl-7,8-carborane anions and have isolated the orange complexes VIIa-c. Complex VIIa isolated from this reaction proved to be identical with the orange complex observed when Id was allowed to stand in dichloromethane. Complexes VIIb and VIIc gave spectra similar to that of VIIa and also to those previously described. ${ }^{38}$ The ${ }^{11} \mathrm{~B}$ NMR spectra were broad with the exception of one doublet that remained unchanged upon broad-band proton decoupling. This suggested the possibility of a phosphine ligand attached to a cage boron atom with $J_{\mathrm{B}-\mathrm{p}}$ of approximately 145 Hz . The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}$ spectra confirmed this hypothesis showing a sharp doublet of doublets at ca. $42-44 \mathrm{ppm}\left[J_{\mathrm{Rh}-\mathrm{P}}=136 \mathrm{~Hz}, J_{\mathrm{P}-\mathrm{P}}=5 \mathrm{~Hz}\right]$ and a broad quartet at approximately 6 ppm that had been previously overlooked. The latter resonance is indicative of phosphorus coupling to ${ }^{11} \mathrm{~B}$. The fact that one phosphine is attached directly to a boron atom is in keeping with the very small phosphorusphosphorus coupling constant observed (only resolved for the rhodium-bound phosphorus; see Figure 11 for the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of VIIa). The ${ }^{1} \mathrm{H}$ NMR spectra all exhibited a doublet of doublets of doublets in the metal hydride region. Single-fre-

Figure 11. ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of $\left[\right.$ closo-1- $\mathrm{Ph}-3,8-\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{Cl}-3-$ $\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] Vlla showing (A) representative $\mathrm{P}_{1}$ coupling to Rh and (B) representative $P_{2}$ coupling to boron.
quency ${ }^{31} \mathrm{P}$ decoupling of the metal hydride resonance in complex VIIa allowed the coupling constants to be determined as follows: $J_{\mathrm{Rh}-\mathrm{H}}=15 \mathrm{~Hz} ; J_{\mathrm{P}_{1}-\mathrm{H}}=42 \mathrm{~Hz} ; J_{\mathrm{P}_{2}-\mathrm{H}}=6 \mathrm{~Hz}$ (where $\mathrm{P}_{1}$ is Rh bound and $P_{2}$ is bound to boron). The ${ }^{1} \mathrm{H}$ and $\left.{ }^{1} \mathrm{H}^{31} \mathrm{P}\right\}$ spectra of VIIb are similar and are shown in Figure 12. It seemed likely that a chlorine atom was albo bonded to the rhodium, and this was confirmed in all three cases by elemental analysis of samples (recrystallized from benzene-ethanol) that had not been exposed to chlorinated solvents. The proposed mechanism for the formation of complexes VIIa-c is shown in Figure 13. We believe that the first step of the reaction involves formation of the respective [closo-3,3-( $\left.\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9} \mathrm{RR}^{\prime}$ ] complexes followed by exchange of the hydride ligand for a chloride through the agency of HCl formed in situ. It would appear that these car-bon-substituted complexes then rapidly dissociate $\mathrm{PPh}_{3}$, which subsequently attacks an activated boron atom and allows the terminal hydride attached to the boron atom to migrate to the

Figure 12. ${ }^{1} \mathrm{H}$ and $\left.{ }^{1} \mathrm{H}^{31} \mathrm{P}\right\}$ Spectra of [closo-1-Me-3,8-( $\left.\mathrm{PPh}_{3}\right)_{2}$-3-Cl-3-$\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] (VIlb): (A) no decoupling; (B) $\mathrm{P}_{1}$ decoupled; (C) $\mathrm{P}_{2}$ decoupled.

Figure 13. Proposed mechanism for the formation of complexes V1la-c.
rhodium. This hypothesis is supported by the results of the reaction of complex Ie with aqueous HCl in ethanol at the reflux temperature which yields complex VIIb. It is also consistent with the instability of complexes Id and Ih in dichloromethane. Complex Id gave VIIa whereas complex Ih produced complex Ik. Therefore, 3,1,2-unsubstituted species do not rearrange readily, presumably due to the stability of the bis(phosphine) chlorides with respect to phosphine dissociation. Thus, complex Ia when reacted with $\mathrm{PPh}_{3}, \mathrm{HBF}_{4}$, and $\mathrm{Me}_{4} \mathrm{NCl}$ in ethanol at the reflux temperature produced Ij .

It seemed likely that for complexes VIIa-c a boron atom on the pentagonal face of the carborane cage which bonds to metal also bonds to $\mathrm{PPh}_{3}$ since coupling of both the metal-bound phosphorus and hydride to this phosphorus atom is observed (vide supra). This hypothesis has been confirmed by a recent X-ray diffraction study of complex VIIa ${ }^{39}$ which shows the $\mathrm{PPh}_{3}$ to be bonded to $\mathrm{B}(8)$, the unique boron atom on the $\mathrm{C}_{2} \mathrm{~B}_{3}$ pentagonal face.

Similar metal-to-boron phosphine migrations have been reported for $10-{ }^{-40}$ and $11^{-1}$ vertex ruthena-, $11^{-41}$ vertex platina- and $12-^{42}$
(39) Day, V. W.; Thompson, M. R., private communication.
vertex nickelacarboranes. Further studies are in progress to determine the nature of the unsaturated species formed by phosphine dissociation in nickel-triad, 12-vertex metallacarboranes.

## Conclusion

While we have not specifically discussed the catalytic properties of the set of three isomeric [closo- $\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{H}) \mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] rhodacarborantes and their derivatives, this subject will be treated along with mechanistic details in a later paper in this series. ${ }^{6 a}$ However, at this point we have shown that these closo 18 -electron, formal Rh (III) species are readily available and that they undergo characteristic reactions at the Rh vertex of the icosahedral cluster. The possible intervention of novel nido- $\mathrm{Rh}(\mathrm{I})$ tautomers as intermediates in some of these reactions is quite likely, and this subject will be addressed in the following contributions to this series. ${ }^{15}$

## Experimental Section

Physical Measurements. The ${ }^{1} \mathrm{H}(200.133 \mathrm{MHz})$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}(81.02$ MHz ) NMR spectra ${ }^{43}$ were recorded on a Bruker WP-200 Fourier transform instrument utilizing a deuterium lock and a B-VT-1000 temperature controller for variable-temperature measurements. The ${ }^{11} \mathrm{~B}$ NMR spectra ${ }^{44}$ were recorded at $80.5,118.0$, or 127.0 MHz on a Fourier transform instrument designed by Professor F. A. L. Anet of this department. IR spectra were recorded as Nujol mulls on a Perkin-Elmer 137 spectrophotometer. Optical rotations were measured with a Per-kin-Elmer 24 IMC polarimeter. Elemental analyses were performed by Schwarzkopf Microanalytical Laboratories, Woodside, NY. Glovebox manipulations were performed in a Vacuum Atmosphere HE-43 facility.

Materials. All solvents were reagent grade (Mallinckrodt) and were distilled from an appropriate drying agent under argon as follows: methanol (magnesium methoxide), diethyl ether (sodium-potassium alloy), benzene and tetrahydrofuran (potassium metal), toluene and heptane (sodium metal). Tetrahydrofuran and diethyl ether were also pretreated with activity 1 alumina (Merck) to remove peroxides. NMR solvents were obtained from commercial sources and dried and degassed prior to use. Triethylphosphine, dimethylphenylphosphine, 1,2-bis(diphenylphosphine)ethane (Strem), fluoboric acid (MCB), tetramethylammonium chloride, triphenylphosphine (Aldrich), hydrogen chloride, carbon monoxide (Liquid Carbonic), and rhodium trichloride trihydrate (Matthey Bishop) were purchased from commercial sources and used as received. Sodium borohydride (Alfa) was dried in vacuo prior to use. lnhibited $n$-butyl acrylate (Eastman) and methyl methacrylate (Aldrich) were passed down a column of alumina and then vacuum distilled from calcium hydride immediately before use. Precursor $\alpha$-phenylacrylic acid was prepared from phenylmalonic acid (Aldrich) according to literature procedures ${ }^{45,46}$ and converted to its ethyl ester by the method of Raber and Gariano. ${ }^{47}$ The product was purified by fractional distillation ( 0.2 $\mathrm{mmHg}, 56^{\circ} \mathrm{C}$ ) and then vacuum distilled from calcium hydride prior to use. Salts of the [nido $\left.-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \mathrm{RR}^{\prime}\right]$ anions, ${ }^{12,48}\left[\mathrm{Rh}_{2}(\mathrm{OAc})_{4} \cdot 2 \mathrm{MeOH}\right]^{21}$ and $\left[\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right],{ }^{49}$ were prepared by literature procedures. The resolving agent $l-N, N, N$-trimethyl( $\alpha$-phenylethyl)ammonium iodide was prepared from $l-\alpha$-phenylethylamine (Aldrich) as previously described. ${ }^{12,50}$ Thin-layer chromatography was performed on Kodak 13181 silica gel with fluorescent indicator. Baker silica gel ( $60-200$ mesh) was employed for column chromatography.

rhodacarboranes. To a solution of [ $\left.\mathrm{Me}_{3} \mathrm{NH}\right]\left[\right.$ nido- $7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}$ ] ( 0.46 $\mathrm{g}, 2.38 \mathrm{mmol})$ in ethanol $(100 \mathrm{~mL})$ was added $\left[\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right](2.0 \mathrm{~g}, 2.16$ mmol ) and the mixture heated at the reflux temperature for ca. 2 h . The reaction mixture was cooled to $40^{\circ} \mathrm{C}$, and the resulting yellow precipitate was separated by filtration and washed with ethanol, yielding la (1.49 $\mathrm{g}, 91 \%)$. In order to remove traces of Rh metal initially present in [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$, the crude product was chromatographed on silica gel, eluting with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The recovered product was recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /ethanol or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /heptane. This preparation has been scaled up to produce as much as 19 g of la in yields of $97 \%$. Complexes $\mathrm{lb}-\mathrm{e}$, lla-c, and 111 were all prepared by analogous routes from the respective carborane anions. Only complexes la, 11a, and 111 were chromatographed as above. An alternative preparation involved reaction of [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ with the carborane anion in methanol at room temperature overnight, followed by heating to the reflux temperature for ca. 1 h . This method was used for the preparation of complexes ld-f. Yields and $\nu_{\mathrm{Rh}-\mathrm{H}}$ are shown in Table IV.

The carbon-deuterated closo-carborane $1,2-\mathrm{D}_{2}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ was prepared by hyrolysis of $1,2-\mathrm{Li}_{2}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}{ }^{51}$ using $\mathrm{D}_{2} \mathrm{O}$ and degraded to the [nido-7,8- $\left.\mathrm{D}_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]^{-}$using excess $\mathrm{NaOC}_{2} \mathrm{H}_{5}$ in $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OD}$ at the reflux temperature. Prior to removal of excess base, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ followed by $\mathrm{H}_{2} \mathrm{O}$ was added to back-exchange the $\mathrm{B}-\mathrm{D}-\mathrm{B}$ bridge deuteron by a proton. The carbon-deuterated anion was reacted with [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ in $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ at the reflux temperature to give lb, which had no detectable carborane $\mathrm{C}-\mathrm{H}$ resonance in the ${ }^{1} \mathrm{H}$ NMR spectrum. No attempt was made to optimize yields of reactions leading to the carbon-deuterated complex. As the precursor closo-1-Me-1,7- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}$ could not be prepared completely free from traces of closo-1, $7-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$, complex lle was always contaminated with lla and hence no elemental analysis was obtained for 1lc. Analytical data for the remaining compounds are shown in Table V , while ${ }^{31} \mathrm{P}\left[{ }^{1} \mathrm{H}\right\}$ and ${ }^{1} \mathrm{H}$ NMR spectra are summarized in Tables 111 and V1, respectively. ${ }^{52} \quad{ }^{11} \mathrm{~B}$ NMR spectra were often broad and uninformative; ${ }^{53}$ however, those spectra that were relatively well resolved are tabulated (Table V11).
(51) Grimes, R, N. "Carboranes"; Academic Press: New York, 1970; and references contained therein.
(52) Proton chemical shifts were referenced to residual protons in the solvent (dichloromethane, $\delta 5.32$, toluene methyl, $\delta 2.09$, tetrahydrofuran $\delta$ 3.58 , with respect to tetramethylsilane). Phosphorus chemical shifts were determined as follows: because the spectrometer was locked on different solvent deuterium resonances (i.e., $\mathrm{CD}_{2} \mathrm{Cl}_{2}, \mathrm{C}_{6} \mathrm{D}_{6}$, or $\mathrm{C}_{6} \mathrm{D}_{5} \mathrm{CD}_{3}$ ), it was necessary to calibrate spectra obtained with the use of each of these lock signals. This was achieved by determining the chemical shift of $\mathrm{PPh}_{3}$ in all the solvent systems used under spectrometer conditions identical with those employed in this study. The ${ }^{31} \mathrm{P}$ chemical shifts are reported with respect to $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ by taking the chemical shift of $\mathrm{PPh}_{3}$ with respect to $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ as -6 ppm as described in: Mann, B. E. J. Chem. Soc., Perkin Trans. 1972, 2, 30.
(53) Very broad ${ }^{11} \mathrm{~B}$ NMR resonances are typical of metallacarboranes containing bulky ligands (e.g., $\mathrm{PPh}_{3}, \mathrm{AsPh}_{3}, \mathrm{P}(p \text {-tolyl })_{3}$ ). ${ }^{\text {af }}$ The analogous complexes with smaller ligands exhibit ${ }^{11}$ B NMR spectra with normal line widths. This effect may be due to the size or molecular volume of the metallacarborane molecule. ${ }^{\text {d }}$ Metallacarboranes with large ligands tumble more slowly and lower rates of molecular reorientation result in more efficient quadrupolar relaxation of the boron nuclei and therefore larger line widths in the "B NMR spectrum. This effect can be duplicated by lowering the temperature or by increasing the viscosity of the solution. (a) Paxson, T. E.; Hawthorne, M. F. J. Am. Chem. Soc. 1974, 96, 4674. (b) Hoel, E. Resolution of [d/-nido-7-Me-7,8- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$and the Preparation of [d-closo-1-Me-3,3- $\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (le ${ }^{*}$ ). Racemic [nido-7,8- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$was resolved by slight modification of the procedure used ${ }^{12}$ to resolve [nido-7-Ph-7,8-C $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}$. Aqueous solutions of $l-N$,$N, N$-trimethyl( $\alpha$-phenylethyl)ammonium iodide ( $81.0 \mathrm{~g}, 0.278 \mathrm{~mol}$ in 350 mL of $\mathrm{H}_{2} \mathrm{O}$ ) and crude K [nido-7-Me-7,8- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] ( $50.0 \mathrm{~g}, 0.268$ mol dissolved in 400 mL of $\mathrm{H}_{2} \mathrm{O}$ ) were mixed. The resulting white precipitate of $\left[l-\mathrm{Me}_{3} \mathrm{NCH}(\mathrm{Me})(\mathrm{Ph})\right]\left[d l\right.$-nido- $\left.7-\mathrm{Me}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ was separated by filtration, washed with $\mathrm{H}_{2} \mathrm{O}$, and dried in vacuo: yield 76.7 $\mathrm{g}, 92 \%,[\alpha]^{25}{ }_{579}-9.0^{\circ}$. All rotations were measured in acetonitrile solvent. The product was recrystallized 18 times from ethanol, after which the total amount recovered was $13.0 \mathrm{~g}(16 \%)$ of $\left[l-\mathrm{Me}_{3} \mathrm{NCH}(\mathrm{Me})-\right.$ $(\mathrm{Ph})]\left[l\right.$-nido-7-Me-7,8- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]: \mathrm{mp} 138.5-140^{\circ} \mathrm{C},[\alpha]^{25}{ }_{579}-16.8^{\circ}$. The $\mathrm{NMe}_{3} \mathrm{H}$ salt was obtained by cation exchange chromatography as previously described. ${ }^{12}$ The crude yield of [ $\mathrm{NMe}_{3} \mathrm{H}$ ][l-nido- 7 - $\mathrm{Me}-7,8$ $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] was 7.64 g ( $86 \%$ ). After recrystallization from hot $\mathrm{H}_{2} \mathrm{O}, 6.68$ g were obtained: $\mathrm{mp} 243-245^{\circ} \mathrm{C} ;[\alpha]^{25}{ }_{579}-5.9^{\circ}$. Complex le* was prepared from [ $\mathrm{NMe}_{3} \mathrm{H}$ ] [l-nido-7-Me-7,8- $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] as described above, giving $[\alpha]^{25}{ }_{579}+5.3^{\circ}$.

Hydrogenation Studies of Ethyl $\alpha$-Phenylacrylate Employing Chiral le* as the Catalyst Precursor. (a) At $25^{\circ} \mathrm{C}$ under 1 atm of $\mathrm{H}_{2}$. The apparatus employed has been previously described. ${ }^{54}$ A $100-\mathrm{mL}$ flask with side arm, containing a solution of le* ( $150 \mathrm{mg}, 0.19 \mathrm{mmol}$ ) in THF ( 30 mL ), was attached to the apparatus and three freeze-pump-thaw cycles were carried out. Hydrogen was then admitted to attain a total pressure of 1 atm and the system allowed to equilibrate at room temperature with vigorous stirring. The alkene ( $0.5 \mathrm{~mL}, 2.98 \mathrm{mmol}$ ) was injected through a septum on the side arm of the flask. The solution at once turned a deeper orange. After 21 h no $\mathrm{H}_{2}$ uptake had been observed. Ethanol was then added to the solution, and when the volume was reduced in vacuo, orange crystals appeared which were identified as complex le* by ${ }^{1} \mathrm{H}$ NMR and IR spectroscopy. When a larger volume of alkene was used ( 1 mL ) orange-red crystals of IVa were isolated from the solution (vide infra).
(b) At $25^{\circ} \mathrm{C}$ and 100 atm of $\mathrm{H}_{2}$. The glass liner of a $100-\mathrm{mL}$ autoclave was charged with a solution of le* ( $120 \mathrm{mg}, 0.155 \mathrm{mmol}$ ) and ethyl $\alpha$-phenylacrylate ( $1 \mathrm{~mL}, 5.96 \mathrm{mmol}$ ) in THF ( 30 mL ) in an argon-filled glove bag. The autoclave was assembled and tightened by hand. After removal from the glove bag, the autoclave was fastened securely and $\mathrm{H}_{2}$ was admitted to a pressure of 1400 psi . After 48 h the autoclave was almost completely vented and then was dismantled in the glove bag. The volatile components were distilled from the green-brown solution on a high-vacuum line and the THF then distilled away from the higher boiling residue to yield 0.5 mL of a viscous, colorless liquid identified as ethyl $\alpha$-phenylpropionate by ${ }^{1} \mathrm{H}$ NMR spectroscopy; $[\alpha]^{25}{ }_{\mathrm{D}} 1.9^{\circ}$. Preparative thick-layer chromatography of the solid, metal-containing residue, eluting with $1: 1 \mathrm{CH}_{2} \mathrm{Cl}_{2} /$ heptane, afforded ca .20 mg of a blue rhodacarborane complex which was not further examined.

Preparation of [closo-1-Me-3,3- $\left(\mathrm{CH}_{2} \mathrm{C}(\mathrm{H}) \mathrm{PhC}(\mathrm{O}) \mathrm{OEt}\right.$ )-3- $\mathrm{PPh}_{3}$ -3,1,2- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (IVa). Ethyl $\alpha$-phenylacrylate ( $1 \mathrm{~mL}, 5.96 \mathrm{mmol}$ ) was added to a solution of le ( $144 \mathrm{mg}, 0.186 \mathrm{mmol}$ ) in THF ( 2 mL ), causing an immediate deepening of the color to red-orange. The solution was stirred at room temperature for 12 h and then concentrated in vacuo to 10 mL . On addition of ethanol ( 10 mL ) red-orange crystals of 1 Va formed. These were recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /ethanol containing ethyl $\alpha$-phenylacrylate ( 0.5 mL ) to prevent decomposition of the product to give lVa ( $45 \mathrm{mg}, 35 \%$ ). ${ }^{1} \mathrm{H}$ NMR $7.48(\mathrm{~m}, 15 \mathrm{H}$, phenyl protons of coordinated $\mathrm{PPh}_{3}$ ), $7.13,6.46(\mathrm{~m}, 5 \mathrm{H}, \mathrm{Hd}), 4.44\left(\mathrm{t}, 1 \mathrm{H}, \mathrm{Hc},{ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}\right.$ $\left.=9,{ }^{3} J_{\mathrm{Hb}-\mathrm{Hc}}=9 \mathrm{~Hz}\right), 4.25\left(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ha},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=9,{ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}=9 \mathrm{~Hz}\right)$, 4.09 (overlapping quartet, $1 \mathrm{H}, \mathrm{He},{ }^{2} J_{\mathrm{He}-\mathrm{Hf}}=11, J_{\mathrm{He}-\mathrm{Hg}}=6 \mathrm{~Hz}$ ), 3.8 m (overlapping quartet, $\left.1 \mathrm{H}, \mathrm{Hf},{ }^{2} J_{\mathrm{He}-\mathrm{Hf}}=11,{ }^{3} J_{\mathrm{Hf}-\mathrm{Hg}}=6 \mathrm{~Hz}\right), 2.43(\mathrm{~s}, \mathrm{br}$, 1 H , carborane $\mathrm{C}-\mathrm{H}), 2.24\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Hb},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=9,{ }^{3} J_{\mathrm{Hb}-\mathrm{Hc}}=9 \mathrm{~Hz}\right)$, $1.59\left(\mathrm{~d}, 3 \mathrm{H}\right.$, carborane $\left.\mathrm{C}-\mathrm{Me},{ }^{4} J_{\mathrm{P}-\mathrm{H}}=2 \mathrm{~Hz}\right), 1.00 \mathrm{ppm}(\mathrm{t}, 3 \mathrm{H}, \mathrm{Hg}$, ${ }^{3} J_{\mathrm{He}-\mathrm{Hg}}=6,{ }^{3} J_{\mathrm{Hf}-\mathrm{Hg}}=6 \mathrm{~Hz}$ ).

The other alkyl complexes were similarly prepared as follows:
[closo-1-Me-3,3-( $\left.\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{C}(\mathrm{O}) \mathrm{OBu}\right)-\mathbf{3}-\mathrm{PPh}_{3}-\mathbf{3 , 1 , 2}-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] ( 1 Vb ). By use of le ( $250 \mathrm{mg}, 0.32 \mathrm{mmol}$ ) and $n$-butyl acrylate ( $5.0 \mathrm{~mL}, 34.80$ mmol ) in THF ( 20 mL ) , $70 \mathrm{mg}(34 \%)$ of 1 Vb was obtained after recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /ethanol. The crystal for the X -ray study was also grown from this solvent combination. ${ }^{1} \mathrm{H}$ NMR $7.44(\mathrm{~m}, 15 \mathrm{H}$, phenyl protons of coordinated $\left.\mathrm{PPh}_{3}\right), 4.07\left(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ha},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=10\right.$, ${ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}=10 \mathrm{~Hz}$ ), 3.68 (overlapping triplet, $1 \mathrm{H}, \mathrm{He},{ }^{2} J_{\mathrm{H} \tau-\mathrm{Hf}}=11,{ }^{3} J_{\mathrm{He}-\mathrm{Hg}}$ $=6 \mathrm{~Hz}$ ), 3.25 (overlapping triplet, $1 \mathrm{H}, \mathrm{Hf},{ }^{2} J_{\mathrm{H}-\mathrm{Hf}}=11,{ }^{3} J_{\mathrm{Hf}-\mathrm{Hg}}=6$ $\mathrm{Hz}), 3.01\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Hc},{ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}=10,{ }^{2} J_{\mathrm{Hc}-\mathrm{Hd}}=6 \mathrm{~Hz}\right), 2.42(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Hd}$, $\left.{ }^{2} J_{\mathrm{Hc}-\mathrm{Hd}}=6 \mathrm{~Hz}\right), 2.31\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Hb},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=10 \mathrm{~Hz}\right), 2.23(\mathrm{~s}$, br, 1 H , carborane $\mathrm{C}-\mathrm{H}$ ), $1.49\left(\mathrm{~d}, 3 \mathrm{H}\right.$, carborane $\mathrm{C}-\mathrm{Me},{ }^{4} J_{\mathrm{P}-\mathrm{H}}=2 \mathrm{~Hz}$ ), 1.25 ,
(54) Potential catalysts are screened utilizing a previously reported procedure and apparatus described: Baker, R. T.: King, R. E., III; Knobler, C. B.; O'Con, C. A.; Hawthorne, M. F. J. Am. Chem. Soc. 1978, 100, 8266.

By use of le ( $300 \mathrm{mg}, 0.387 \mathrm{mmol}$ ) and methyl methacrylate ( 3.0 $\mathrm{mL}, 32.10 \mathrm{mmol}$ ) in THF ( 20 mL ), $65 \mathrm{mg}(27 \%)$ of 1 Vc was isolated after recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /ethanol. ${ }^{1} \mathrm{H}$ NMR $7.43(\mathrm{~m}, 15 \mathrm{H}$, phenyl protons of coordinated $\left.\mathrm{PPh}_{3}\right), 4.21\left(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ha},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=9\right.$, $\left.{ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}=9 \mathrm{~Hz}\right), 3.27(\mathrm{~s}, 3 \mathrm{H}, \mathrm{He}), 3.17\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Hc},{ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}=9,{ }^{3} J_{\mathrm{Hc}-\mathrm{Hd}}\right.$ $=7 \mathrm{~Hz}), 2.28\left(\mathrm{~s}\right.$, br, carborane $\mathrm{C}-\mathrm{He}, 2.05\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Hb},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=9\right.$ $\mathrm{Hz}), 1.50\left(\mathrm{~d}, 3 \mathrm{H}\right.$, carborane $\left.\mathrm{C}-\mathrm{Me},{ }^{4} \mathrm{~J}_{\mathrm{P}-\mathrm{H}}=2 \mathrm{~Hz}\right), 0.91 \mathrm{ppm}(\mathrm{d}, 3 \mathrm{H}$, $\left.\mathrm{Hd},{ }^{3} J_{\mathrm{Hc}-\mathrm{Hd}}=7 \mathrm{~Hz}\right)$.
[closo-1,2-(Me) ${ }_{2}$-3,3- $\left(\mathrm{CH}_{2} \mathrm{C}(\mathrm{H}) \mathrm{MeC}(\mathrm{O}) \mathrm{OMe}^{2}-\mathrm{PPh}_{3}-3,1,2-\right.$ $\mathbf{R h C}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] (IVd). By use of [exo-nido- $\left.\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Rh}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10} \mathrm{Me}_{2}\right)\right]^{15}(200$ $\mathrm{mg}, 0.254 \mathrm{mmol}$ ) and methyl methacrylate ( $1.5 \mathrm{~mL}, 16.10 \mathrm{mmol}$ in THF ( 20 mL ) , 28 mg ( $18 \%$ ) of IVd was isolated after recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /ethanol. ${ }^{1} \mathrm{H}$ NMR 7.50, $7.35(\mathrm{~m}, 15 \mathrm{H}$, phenyl protons of coordinated $\mathrm{PPh}_{3}$ ), $3.87\left(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ha},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=10,{ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}=10 \mathrm{~Hz}\right.$ ), 3.75 $(\mathrm{s}, 3 \mathrm{H}, \mathrm{He}), 3.00\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Hc},{ }^{3} J_{\mathrm{Hc}-\mathrm{Hd}}=7,{ }^{3} J_{\mathrm{Ha}-\mathrm{Hc}}=10 \mathrm{~Hz}\right), 1.60(\mathrm{~m}$, $\left.1 \mathrm{H}, \mathrm{Hb},{ }^{2} J_{\mathrm{Ha}-\mathrm{Hb}}=10 \mathrm{~Hz}\right), 1.42\left(\mathrm{~d}, 3 \mathrm{H}\right.$, carborane $\mathrm{C}-\mathrm{Me},{ }^{4} J_{\mathrm{P}-\mathrm{H}}=3$ $\mathrm{Hz}), 1.36\left(\mathrm{~s}, 3 \mathrm{H}\right.$, carborane C-Me), $0.51 \mathrm{ppm}\left(\mathrm{d}, 3 \mathrm{H}, \mathrm{Hd},{ }^{3} J_{\mathrm{Hc}-\mathrm{Hd}}=\right.$ 7 Hz ).

Thermal Rearrangement of [closo-1-n-Bu-3,3-( $\left.\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{H}-3,1,2-$ $\mathbf{R h C} \mathbf{C}_{2} \mathbf{B}_{9} \mathbf{H}_{\mathbf{1}}$ ] (If to If'). A solution containing If ( $0.50 \mathrm{~g}, 0.61 \mathrm{mmol}$ ) and $\mathrm{PPh}_{3}(0.81 \mathrm{~g}, 3.09 \mathrm{mmol})$ in THF ( 50 mL ) was heated at the reflux temperature for 72 h . The solvent was then removed in vacuo and the
resulting solid was recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /heptane, affording offwhite crystals of $1 \mathrm{f}^{\prime}(75 \mathrm{mg}, 15 \%) .{ }^{55} \quad$ The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of $1 \mathrm{f}^{\prime}$ in $20 \% \mathrm{CD}_{2} \mathrm{Cl}_{2} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ displayed the second-order ABM portion of an ABMX spin system centered at $31.6 \mathrm{ppm}\left(\mathrm{A}=\mathrm{B}={ }^{31} \mathrm{P}, I=1 / 2 ; \mathrm{M}=\right.$ ${ }^{103} \mathrm{Rh}, I=1 / 2 ; \mathrm{X}={ }^{1} \mathrm{H}, I=1 / 2$ ).
Preparation of [closo-3,3-( $\left.\left.\mathbf{P E t}_{3}\right)_{2}-\mathbf{3}-\mathrm{H}-\mathbf{3 , 1 , 2}-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ (Ig). Method A. To a solution of $\left[\mathrm{Rh}_{2}(\mathrm{OAc})_{4} \cdot 2 \mathrm{MeOH}\right](275 \mathrm{mg}, 0.54 \mathrm{mmol})$ in methanol ( 30 mL ) was added $48 \%$ aqueous $\mathrm{HBF}_{4}(1 \mathrm{~mL}$ ), and the blue solution was held at $60^{\circ} \mathrm{C}$ for 16 h , yielding a green solution of $\left[\mathrm{Rh}_{2}\right]\left[\mathrm{BF}_{4}\right]_{4}$. The solution was transferred to the glovebox, $\mathrm{PEt}_{3}(400$ $\mathrm{mg}, 3.40 \mathrm{mmol}$ ) added, and the resulting bright yellow solution stirred for 2 h . The solvent was removed and the residue dried on a high-vacuum line to remove water and acetic acid. The residue was then dissolved in methanol ( 50 mL ) and [ $\mathrm{Me}_{3} \mathrm{NH}$ ] [nido-7, $8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}$ ] ( $215 \mathrm{mg}, 1.10$ mmol ) added. The solution turned orange; yellow crystals of 1 g precipitated which were separated by filtration, washed with methanol ( $2 \times 20$ mL ), and dried in vacuo, yielding $420 \mathrm{mg}(82 \%)$ of $\mathrm{Ig}\left(\nu_{\mathrm{Rh}}-\mathrm{H} 2040 \mathrm{~cm}^{-1}\right)$.
Method B. Complex la ( $761 \mathrm{mg}, 1.00 \mathrm{mmol}$ ) was dissolved in THF $(200 \mathrm{~mL})$ and $\mathrm{PEt}_{3}(265 \mathrm{mg}, 3.08 \mathrm{mmol})$ added in the glovebox. The reaction was stirred for 10 h and then heated to reflux for 1 h . Addition

${ }^{a}$ The number of boron atoms represented by each resonance is given in parentheses; chemical shifts are in ppm with respect to external $\mathrm{Bl}_{3}: \mathrm{OE}_{2} . \quad{ }^{b}$ Spectrum recorded at 127.1 MHz in tetrahydrofuran. ${ }^{c}$ Spectrum recorded at 111.7 MHz in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$
${ }^{d}$ Spectrum recorded at 111.7 MHz in $\mathrm{CDCl}_{3}$
of absolute ethanol ( 100 mL ) followed by concentration of the solution to 70 mL in vacuo afforded a light yellow powder which on recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /heptane yielded 430 mg ( $91 \%$ ) of lg.

Preparation of [closo-3,3-( $\mathbf{P M e}_{2} \mathbf{P h}$ )-3-H-3,1,2- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (Ih). Complex lh could be prepared by method A or B above.

Method A. By use of $\left[\mathrm{Rh}_{2}(\mathrm{OAc})_{4} \cdot 2 \mathrm{MeOH}\right](275 \mathrm{mg}, 0.54 \mathrm{mmol})$, $\mathrm{HBF}_{4}(1 \mathrm{~mL}), \mathrm{PMe}_{2} \mathrm{Ph}(470 \mathrm{mg}, 3.40 \mathrm{mmol})$, and $\left[\mathrm{Me}_{3} \mathrm{NH}\right][$ nido- 7,8 $\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}$ ] ( $215 \mathrm{mg}, 1.10 \mathrm{mmol}$ ), $440 \mathrm{mg}(79 \%)$ of lh was obtained after recrystallization from THF/heptane ( $\nu_{\mathrm{Rb}-\mathrm{H}} 2040,2060 \mathrm{~cm}^{-1}$ ).

Method B. A yield of $470 \mathrm{mg}(92 \%)$ of complex lh was obtained from la ( $761 \mathrm{mg}, 1.00 \mathrm{mmol}$ ) and $\mathrm{PMe}_{2} \mathrm{Ph}(425 \mathrm{mg}, 3.08 \mathrm{mmol})$ after recrystallization from THF/heptane.

Preparation of [closo-3,3-( $\left.\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2} \mathrm{PPh}_{2}\right)-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (li). Complex li was prepared according to method B from la ( 761 mg , 1.00 mmol ) and $\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2} \mathrm{PPh}_{2}$ ( $410 \mathrm{mg}, 1.03 \mathrm{mmol}$ ). Recrystallization of the resulting yellow powder from THF/heptane, yielded 580 $\mathrm{mg}(91 \%)$ of li ( $\nu_{\mathrm{Rh}-\mathrm{H}} 2050 \mathrm{~cm}^{-1}$ ).

Preparation of [closo-3,3-( $\left.\left.\mathrm{PPh}_{3}\right)_{2}-\mathbf{3 - C l}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ (Ij). Complex la ( $102 \mathrm{mg}, 0.134 \mathrm{mmol}$ ) was heated to the reflux temperature for 2 h in $\mathrm{CHCl}_{3}$ solution ( 40 mL ) in the presence of concentrated aqueous $\mathrm{HCl}(10 \mathrm{~mL})$, yielding an orange-red solution. The organic layer was separated, washed with $\mathrm{H}_{2} \mathrm{O}(5 \times 20 \mathrm{~mL})$, and dried over anhydrous $\mathrm{MgSO}_{4}$. Concentration of the filtered $\mathrm{CHCl}_{3}$ solution, followed by addition of ethanol gave 78 mg ( $73 \%$ ) of crystalline 1 j .

Preparation of [closo-3,3-( $\left.\mathrm{PMe}_{2} \mathrm{Ph}\right)_{2}-\mathbf{3 - C l}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (Ik). Complex $1 \mathrm{~h}(256 \mathrm{mg}, 0.50 \mathrm{mmol})$ was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$. The resulting solution was stirred for 12 h and layered with heptane to yield large red-orange blocks of $1 \mathrm{k}(260 \mathrm{mg}, 95 \%)$.

Preparation of [closo-2,2-( $\left.\mathrm{PEt}_{3}\right)_{2}$-2-H-2,1,7-RhC $\mathrm{C}_{9} \mathrm{~B}_{11}$ ] (IId). To a stirred solution of 1la ( $1.52 \mathrm{~g}, 2.00 \mathrm{mmol}$ ) in benzene $(200 \mathrm{~mL})$ was added $\mathrm{PEt}_{3}(0.94 \mathrm{~g}, 4.00 \mathrm{mmol})$. The solution was stirred for 8 h and the solvent then extracted in vacuo. The resulting yellow oil was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, filtered, and layered with heptane, affording light

yellow crystals of Ild ( $709 \mathrm{mg}, 75 \%$ ) ( $\nu_{\mathrm{Rh}-\mathrm{H}} 2040,2080 \mathrm{~cm}^{-1}$ ).
Preparation of [closo-2,2-( $\left.\left.\mathrm{PMe}_{2} \mathrm{Ph}\right)_{2}-\mathbf{2 - H}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ (IIe). To a benzene ( 200 mL ) solution of Ila ( $1.52 \mathrm{~g}, 2.00 \mathrm{mmol}$ ) $\mathrm{PMe}_{2} \mathrm{Ph}(1.10$ $\mathrm{g}, 4.00 \mathrm{mmol}$ ) was added and the solution stirred for 8 h . Addition of ethanol ( 100 mL ) followed by slow evaporation to 100 mL yielded a light yellow microcrystalline solid, which on recrystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ / heptane afforded light yellow crystals of lle ( $0.820 \mathrm{~g}, 80 \%$ ) ( $\nu_{\mathrm{Rh}-\mathrm{H}} 2033$ $\mathrm{cm}^{-1}$ ).

Preparation of [closo-2- $\mathrm{PPh}_{3}-\mathbf{2 - C l}-\mathbf{2}, 1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (V). A solution of $1 \mathrm{Ia}(2.28 \mathrm{~g}, 3.00 \mathrm{mmol})$ in benzene $(200 \mathrm{~mL})$ containing $\mathrm{CCl}_{4}(10 \mathrm{~mL})$ was heated to the reflux temperature for 12 h , during which time the initial yellow solution became dark red. The solution was reduced to dryness on silica gel, applied to a silica gel column, and eluted with 5:1 heptane/benzene to collect the red band (elution with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ gives 1la). On evaporation of the solvent, followed by extraction with benzene, filtration, and addition of heptane, traces of 1 la were obtained after 24 $h$. Filtration, further addition of heptane, and concentration in vacuo yielded V ( $565 \mathrm{mg}, 35 \%$ ).

Preparation of [closo-2- $\left.\mathrm{PPh}_{3}-2-\mathrm{CO}-2-\mathrm{Cl}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ (VIa). When CO was passed through a red solution of $V(500 \mathrm{mg}, 0.938 \mathrm{mmol})$ in benzene ( 25 mL ) the color gradually became light yellow. Addition of heptane precipitated a yellow powder that was recrystallized from

${ }^{a}$ Estimated standard deviations are given in parentheses. ${ }^{b}$ Anisotropic thermal parameters. ${ }^{c}$ The form of the anisotropic thermal ellipsoid is exp $\left[-\left(\beta_{11} h^{2}+\beta_{22} k^{-2}+\beta_{33} l^{2}+2 \beta_{12} h k+2 \beta_{13} h l+2 \beta_{23} k l\right)\right]$ all parameters have been multiplied by $10^{4}$. ${ }^{d} x, v$, and $z$ are the fractional coordinates of the group origin and $\phi, \theta$, and $\rho$, the rotation angles, in radians, as defined by: Scheringer, C. Acta Crystallogr. 1963. 16. 546.

CO-saturated benzene/heptane at ca. $5^{\circ} \mathrm{C}$, affording 244 mg ( $46 \%$ ) of VIa. Attempted recrystallization from argon-saturated solvents regenerated the red color of the starting material ( $\nu_{\mathrm{CO}} 2060 \mathrm{~cm}^{-1}$ ).

Preparation of [closo-2- $\mathrm{PPh}_{3}-2-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}-2-\mathrm{Cl}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] (VIb). The pyridine adduct of V , namely Vlb , could be precipitated as orange plates from benzene/pyridine solution by addition of heptane. A sample thus isolated was recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2} /$ heptane/pyridine and an elemental analysis confirmed the proposed stoichiometry. Attempted recrystallizations from solution not containing pyridine resulted in a darkening of the solution from orange to red ( $\nu_{\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}} 1610 \mathrm{~cm}^{-1}$ ).

Preparation of [closo-1-Ph-3,8-( $\left.\mathrm{PPh}_{3}\right)_{2}$-3-Cl-3-H-3,1,2- $\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] (VIIa). A $250-\mathrm{mL}$ Schlenk flask was charged with [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ ( 2.00 $\mathrm{g}, 2.16 \mathrm{mmol}), \mathrm{PPh}_{3}(0.566 \mathrm{~g}, 2.16 \mathrm{mmol})$, and [ $\mathrm{Me}_{4} \mathrm{~N}$ ][nido-7- $\mathrm{Ph}-7,8-$ $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right](0.625 \mathrm{~g}, 2.18 \mathrm{mmol})$. Ethanol ( 150 mL ) was added, followed by $48 \%$ aqueous $\mathrm{HBF}_{4}(1.75 \mathrm{~mL}, 8.75 \mathrm{mmol})$. The reaction mixture was heated to the reflux temperature for 7 h and allowed to cool to $\mathrm{ca} .40^{\circ} \mathrm{C}$. The light orange precipitate was isolated by filtration and washed with ethanol and diethyl ether to give V1la ( $1.56 \mathrm{~g}, 83 \%$ ). The complex was recrystallized from benzene/ethanol to give bright orange fluffy crystals ( $\nu_{\mathrm{Rh}-\mathrm{H}} 2100 \mathrm{~cm}^{-1}$ ).

Preparation of [closo-1-Me-3,8- $\left(\mathbf{P P h}_{3}\right)_{2}-\mathbf{3 - C l}-3-\mathrm{H}-3,1,2-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{9}$ ] (VIIb). Method A. To a solution containing $\mathrm{PPh}_{3}(87 \mathrm{mg}, 0.33 \mathrm{mmol})$ and concentrated hydrochloric acid ( $0.14 \mathrm{~mL}, 1.65 \mathrm{mmol}$ ) in ethanol ( 40 mL ) was added complex Ie ( $256 \mathrm{mg}, 0.33 \mathrm{mmol}$ ). After the mixture was heated to the reflux temperature for 1 h a deep red solution had formed from which an orange solid rapidly precipitated. The mixture was then stirred at room temperature overnight. The precipitate was isolated by
filtration and recrystallized from benzene/ethanol, affording 125 mg ( $47 \%$ ) of VIlb ( $\nu_{\mathrm{R} h-\mathrm{H}} 2100 \mathrm{~cm}^{-1}$ ). A higher yield of Vllb was obtained ( $185 \mathrm{mg}, 69 \%$ ) employing $48 \%$ aqueous $\mathrm{HBF}_{4}(0.7 \mathrm{~mL}, 3.3 \mathrm{mmol}$ ) and $\mathrm{NMe}_{4} \mathrm{Cl}(72 \mathrm{mg}, 0.67 \mathrm{mmol})$ in place of the HCl .

Method B. To a solution of [ $\left.\mathrm{NMe}_{3} \mathrm{H}\right]\left[\right.$ nido- $\left.7-\mathrm{Me}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right](624$ $\mathrm{mg}, 3.00 \mathrm{mmol})$ in ethanol $(100 \mathrm{~mL})$ was added [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right](2.778$ $\mathrm{g}, 3.00 \mathrm{mmol}), \mathrm{PPh}_{3}(786 \mathrm{mg}, 3.00 \mathrm{mmol})$, and $48 \% \mathrm{HBF}_{4}(2.4 \mathrm{~mL}$, 12.00 mmol ). The mixture was heated to the reflux temperature. After 15 min an orange precipitate began to replace the red suspension of [ $\left.\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right]$ and after 2 h the precipitate was completely orange. Heating was continued for 10 h . The precipitate was then isolated by filtration, washed with ethanol, and recrystallized from benzene/ethanol to yield bright orange crystals of V1lb $(1.65 \mathrm{~g}, 68 \%)$.

Preparation of [closo-1,2-(Me) $\mathbf{2}^{-3,8-\left(\mathrm{PPh}_{3}\right)_{2}-3-\mathrm{Cl}-3-\mathrm{H}-3,1,2-1}$ $\mathbf{R h C}_{2} \mathbf{B}_{9} \mathbf{H}_{8}$ ] (VIIc). Method B, above, was employed with [ $\mathrm{NMe}_{3} \mathrm{H}$ ]-[nido-7,8-Me ${ }_{2}-7,8-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] ( $442 \mathrm{mg}, 2.00 \mathrm{mmol}$ ), $\left[\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{RhCl}\right](1.852$ $\mathrm{g}, 2.00 \mathrm{mmol}), \mathrm{PPh}_{3}(524 \mathrm{mg}, 2.00 \mathrm{mmol})$, and $48 \%$ aqueous $\mathrm{HBF}_{4}(1.6$ $\mathrm{mL}, 8.00 \mathrm{mmol}$ ) in ethanol ( 45 mL ). After the mixture was heated to the reflux temperature for 2 h the resulting orange precipitate was recrystallized from benzene/ethanol to yield $1.06 \mathrm{~g}(64 \%)$ of VIlc ( $\nu_{\mathrm{Rh}-\mathrm{H}}$ $2050 \mathrm{~cm}^{-1}$ ).

Reaction of Ia with $\mathrm{HBF}_{4}, \mathbf{P P h}_{3}$, and $\mathbf{N M e}_{4} \mathbf{C l}$. A mixture of la ( 380 $\mathrm{mg}, 0.50 \mathrm{mmol}), \mathrm{NMe}_{4} \mathrm{Cl}(60 \mathrm{mg}, 0.525 \mathrm{mmol}), \mathrm{PPh}_{3}(131 \mathrm{mg}, 0.50$ mmol ), and $48 \%$ aqueous $\mathrm{HBF}_{4}(1.0 \mathrm{~mL}, 5.0 \mathrm{mmol}$ ) in ethanol ( 40 mL ) was heated at the reflux temperature for 16 h , forming an orange precipitate. This was extracted into benzene ( 100 mL ) and heptane ( 25 mL ) added. On concentration of the solution in vacuo, a mixture of orange

Table X. Positional (in lractional Coordinates) and Thermal Parameters ${ }^{a}$ for the Non-Group Atoms of $\left[\right.$ closo-2-Cl-2- $\left.\mathrm{PPl}_{3}-2,1,7-\mathrm{RhC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11} \cdot \mathrm{C}_{6} \mathrm{H}_{6}\right]$ (V)

${ }^{a}$ Estimated standard deviations in the least significant figures are given in parentheses. ${ }^{b}$ Anisotropic thermal parameters. ${ }^{c}$ The expression for the anisotropic temperature is of the form $\exp \left[-\left(\beta_{11} h^{2}+\beta_{22} k^{2}+\beta_{33} l^{2}+2 \beta_{12} h k+2 \beta_{13} h l+2 \beta_{23} k l\right)\right]$, $d x$, $r$, and $=$ are the fractional coordinates of the origin of the rigid group and $\phi, \theta$, and $\rho$, the rotation angles, in radians, described by: Scheringer, C. Acta Crystallogr. 1963,16, 546.
and yellow crystals formed. When a second recrystallization was attempted, only the orange product redissolved. Addition of heptane afforded $150 \mathrm{mg}(38 \%)$ of lj identified by comparison of its 1 R spectrum and a thin-layer chromatogram with those of an authentic sample of 1 j . The yellow crystals were identified as starting complex la by IR and ${ }^{1} \mathrm{H}$ NMR spectroscopy.

Molecular Structure Determination for Complex IVb. The crystal chosen for data collection was in the shape of an elongated octahedron $(0.30 \mathrm{~mm} \times 0.40 \mathrm{~mm})$ and was bounded by faces of the forms $\{3,0,2\}$, $\{-3,0,2\},[1,1,0\}$, and $\{-1,1,0\}$. The crystal was mounted in a arbitrary direction and transferred to a Picker FACS-1 automated diffractometer. Orientation of the crystal and crystal system followed autoindexing eight accurately centered reflections found photographically. The orthorhombic nature of the unit cell was confirmed by the observation of mirror planes perpendicular to each reciprocal axis. Preliminary data were then collected to identify the intense high-angle data. Accurate cell constants (Table V111) were obtained by a least-squares fit of 19 reflections in the range $5^{\circ} \leq 2 \theta \leq 34^{\circ}$.

Data were collected in the $\theta-2 \theta$ scan mode to a $(\sin \theta) / \lambda$ limit of 0.595 $\AA^{-1}$ with Zr -filtered Mo $\mathrm{K} \alpha$ radiation. Three intense reflections, 290, 526 , and $13,2,-6$ were monitored every 101 reflections as a check on the stability of the experiment. Intensities of these standards fluctuated only slightly during the course of data collection. A constant scan rate of $2^{\circ} / \mathrm{min}$ was used with a scan range of $(2.0+0.692 \tan \theta)^{\circ}$. A $10-\mathrm{s}$ background count was taken at each end of the scan. One quadrant of data ( $+h,+k,+/-l, 5897$ reflections) were collected. Of this total, 3159 reflections were considered observed (i.e., $I>3 \sigma(I)$ ) and were corrected for Lorentz, polarization, and absorption effects. One octant of data ( 3196 reflections) was extracted and of this total, 2161 were considered observed (i.e., $I>3 \sigma(I)$ ) and were corrected for Lorentz, polarization, and absorption effects. The observed systematic absences $h 00, h=2 n$ $+1,0 k 0, k=2 n+1$, and $00 l, l=2 n+1$ indicated the space group to
be $P 2_{1} 2_{1} 2_{1}$. The structure was solved by using one octant $(+h,+k,+l)$ of observed data by standard Patterson-Fourier techniques ${ }^{56}$ and refined in several cycles of full-matrix least-squares. In these and subsequent refinements, the Rh and P atoms were treated as anomalous scatterers, ${ }^{57}$ the positional and isotropic thermal parameters of the cage atoms, the positional and anisotropic thermal parameters of the remaining non-hydrogen non-phenyl carbon atoms, and the scale factor were allowed to vary. The phenyl rings on the phosphorus atoms were treated as rigid groups with $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ set as 1.39 and $1.00 \AA$, respectively. The positional, rotational, and overall thermal parameters of these groups were allowed to vary.

At this point, refinement was continued on the originally chosen isomer with the full data set $(+h,+k, \pm l)$ and also on its enantiomer. Refinement converged to an agreement factor of 0.069 for the former and 0.070 for the latter (the corresponding weighted agreement factors are 0.080 and 0.081 , respectively). This represents a certainty at the $99 \%$ confidence level that the originally chosen molecule is the correct stereoisomer. ${ }^{58}$ Final positional and thermal parameters are given in Table 1X.

Molecular Structure Determination of Complex V. A representative crystal ( $0.35 \mathrm{~mm} \times 0.22 \mathrm{~mm} \times 0.27 \mathrm{~mm}$ ) was chosen for data collection and was mounted in an arbitrary orientation and transferred to a Syntex Pil automated diffractometer. The crystal was maintained at 119 K during the preliminary experiments and data collection. Orientation of
(56) Programs used in this work include locally written data reduction and absorption programs and locally revised versions of ORFLS, ORFFE, ORTEP, and MULTAN.

(58) Hamilton, W. C. Acta Crystallogr. 1965, I8, 502.
the crystal and crystal system determination followed the autoindexing of seven accurately centered reflections found photographically. An axial photograph of the $b$ axis revealed a mirror plane. The orientation matrix obtained from these data was used to index 15 accurately centered high-angle reflections ( $18^{\circ}<2 \theta<27^{\circ}$ ). A least-squares fit of these reflections yielded the cell constants found in Table VIII.

Data were collected in the $\theta-2 \theta$ scan mode to a $(\sin \theta) / \lambda$ limit of 0.60 $\AA^{-1}$ with graphite-monochromatized Mo K $\alpha$ radiation. Three intense reflections, $2,-2,6,1,6,-5$, and $-5,5,-3$, were monitored every 100 reflections as a check on the stability of the experiment. Intensities of these standards fluctuated only slightly during the course of the experiment. A constant scan rate of $3^{\circ} / \mathrm{min}$ was used with a scan range of $1.1^{\circ}$ on either side of $\mathrm{Mo} \mathrm{K} \alpha_{1}$ and $\mathrm{MoK} \alpha_{2}$. The background time to scan ratio was 1. One quadrant of data ( 5298 reflections) were collected and of this total 4389 were considered observed (i.e., $I>3 \sigma(I)$ ) and were corrected for Lorentz and polarization effects. The raw data were also corrected for absorption by an empirical method based on the variation in intensity of three reflections about $\chi=270^{\circ}$. The reflections used and their $2 \theta$ values are $5,-1,1,18.89^{\circ} ; 7,-1,3,30.19^{\circ}$; and $10,-2,3,40.61^{\circ}$. The systematic absences $0 k 0, k=2 n+1$, and $h 0 l, h+l=2 n+1$, indicated the space group to be $P 2_{1} / n$. The $\mathrm{Rh}, \mathrm{P}$, and Cl atoms were located from a Patterson map and Fourier syntheses phased by these and successively added atoms allowed the location of all non-hydrogen atoms, including the benzene of crystallization. At this point the phenyl groups were treated as rigid groups with $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ set at 1.39 and $1.00 \AA$, respectively. In subsequent refinement, the positional parameters and overall temperature factor of each group were allowed to vary. Fullmatrix least-squares varying all positional and isotropic thermal parameters and the scale factor resulted in an agreement factor of 0.066 . The carbon atom positions of the carborane fragment were clearly distinguishable at this point, corresponding to their larger scattering ability. Difference maps at this point revealed the locations of all the carborane hydrogens. Two more cycles of full-matrix least-squares converged to an agreement factor of 0.039 . In these final cycles of refinement all atomic positions and thermal parameters (anisotropic for the $\mathrm{Rh}, \mathrm{P}$, and Cl atoms, isotropic for all other atoms), and the scale factor were allowed to vary. In the final cycle of least-squares the largest shift to standard deviation ratio was 0.13 and most were less than 0.05 . A final difference Fourier synthesis revealed no significant peaks. Final positional and thermal parameters are given in Table X .

Scattering factors were taken from the "International Tables for X-ray Crystallography", and anomalous dispersion terms were included for the $\mathrm{Rh}, \mathrm{P}$, and Cl atoms. ${ }^{57}$

Acknowledgment. We thank Dr. D. C. Busby for providing samples of complex III and for obtaining some of the ${ }^{11} \mathrm{~B}$ NMR spectra and Dr. C. A. O'Con for obtaining some of the ${ }^{11} \mathrm{~B}$ NMR spectra. We also thank Susan Heytens for the illustrations and Matthey Bishop for a generous loan of rhodium. In addition, we gratefully acknowledge National Science Foundation Grant CHE77-05926 for the purchase of the Bruker NMR spectrometer and Grant CHE77-22910 for support of this research. Computing costs were supported by an intramural grant from the UCLA Office of Academic Computing.
