Revised Manuscript Received April 9, 1984

The cytochalasans are molecules of unique biological activity and structural complexity.1 Here we report the first total synthesis of representative carbocyclic cytochalasans,² structures 18 and 19, which are closely related to cytochalasin D (1) and zygosporin $G(2)^{3}$

1, X=Z=OH, $Y=CH_3$; C_{21} -(S) 18, X = Z = Y = H, C_{21} (R) 21, X=H, Z=OH, Y=CH3; C21 (S)

2, Z = OH, $Y = CH_3 : C_{21}$ -(S) 19. Z=Y=H: C₂₁-(R)

In 1978, we described the advantages of using N-acylpyrrolinones for Diels-Alder reactions in the cytochalasin area and a means to control five of the isoindolone asymmetric centers via the least hindered endo transition state.⁴ This same selectivity is maintained with doubly activated dienophiles⁵ and is especially high in the optimized system of Scheme I. The unstable dienophile 4, obtained by a conventional sequence from succinimide (via 3)^{5,6} reacts with triene 5^5 at room temperature to give a >15:1 mixture of the desired adduct 6 and a minor isomer with the same regiochemistry but unknown stereochemistry. Since 4 is too sensitive for purification, we can only estimate the yield of 4 + $5 \rightarrow 6$ as >90%, but the overall yield of 6 from 3 is 77% on 2-g scale.

The last four carbons of the 11-membered carbocycle must now be introduced, and they must be incorporated into a sulfur-containing ring in order to use the ring expansion strategy that we had developed earlier.⁷ After a long search, this problem has been solved by using thioaldehyde technology.⁸ Reaction of 6 with phenacyl thiol/ K_2CO_3 -THF affords the phenacyl sulfide 7 (88%) and sunlamp irradiation generates the reactive thioaldehyde 8. When this experiment is performed in the presence of 2-(tert-butyldimethylsiloxy)butadiene, a 3:2 diastereomer mixture of thio-Diels-Alder adducts 9 can be isolated. Treatment with

DBU/THF (0 °C) improves the isomer ratio to 10:1, and chromatographic separation affords the major isomer in 60% yield based on 8. After ketone reduction and N-benzovl cleavage with LiBH₄/ether followed by silvl ether cleavage (Et₃NH⁺ F^- , CH₃OH, 6 h), 50-60% overall to 10, the stage is set for 11membered ring construction.

The key reaction involves the 2,3-sigmatropic rearrangement of a bicyclic ylide $13.^7$ This ylide can be generated by heating iodide 12 in acetonitrile/ K_2CO_3 . In practice the more stable chloride 11 is made from $10 + Bu_3P/CCl_4$ (100%) and is stirred with NaI, K₂CO₃, and CH₃CN, 4 h at 70 °C. A 1.3:1 mixture of two diastereomers 14 is formed in 60% yield based on 11. Both isomers have the crucial E-double-bond geometry, and must differ at the new asymmetric (bridgehead) carbon.

The last stages of synthesis require removal of sulfur and silicon, transformations that (in retrospect) are quite simple. Sulfur methylation of the major ring-expansion product 14 (+O- $(CH_3)_3BF_4$, DME) followed by Zn/CH_3CO_2H affords the sulfide 15, 92%. Pyrolysis of the derived sulfoxide 16 (MCPBA, 90%)

in xylene, CaCO₃, 140 °C, forms a single olefin 17 (E,E geometry) in 91% yield. After desilylation with BF₃·AcOH/CH₂Cl₂, O °C, 17 is converted into the cytochalasin D derivative 18 (80%).

For synthesis of the zygosporin G substitution pattern, a similar sequence can be used. Desilylation of 16 without allylic inversion is accomplished with CsF/Me₂SO, 1.5 h at 20 °C, followed by sulfoxide pyrolysis as before. The product 19 is obtained in a 10:1 ratio with 18, 63%.

To prove the stereochemistry which has been drawn for these products, a chemical correlation with cytochalasin D has been performed. The details are described in the supplementary material, but the key experiments involve ozonolysis, NaBH₄ reduction, and acylation of 18, the diastereomer pair 20 (derived from 6), and 21 (derived from natural 1). This degradation sequence converts 20 into two isomeric tetraacetates, 22 and 23. Similar degradation of 21 affords 23 while synthetic 18 gives 22. These results prove that isoindolone Diels-Alder stereochemistry is correct and is retained to the end of our synthesis.

In conclusion, we have developed an approach for synthesis of the zygosporin G-cytochalasin D ring systems, 3% overall from succinimide. Subsequent papers will deal with 11-membered ring stereochemistry and functionality.

A Remarkable Alkali-Metal-Centered Zirconium Cluster in Potassium Hexazirconium Tetradecaiodide (Zr₆I₁₄K): Synthesis and Characterization

Jerome D. Smith and John D. Corbett*

Ames Laboratory¹ and Department of Chemistry Iowa State University, Ames, Iowa 20011 Received April 27, 1984

Synthetic efforts to identify important products in the reactions of zircaloy (~98% Zr) cladding with prominent fission products have led to the discovery of two zirconium iodides containing octahedral metal clusters, purportedly Zr_6I_{12} and $CsZr_6I_{14}$.²⁻⁴ The generally low yield of these products led us to attempt syntheses of the ternary phase utilizing other alkali metals. Reaction of KI, ZrI₄, and Zr metal resulted in a product with powder pattern closely resembling that of $CsZr_6I_{14}$ but, surprisingly, with larger lattice parameters. Subsequent studies indicate this compound is the first example of an unprecedented configuration, an octahedral metal cluster the center of which is occupied by an alkali

Figure 1. $Zr_6I_{14}K_{10}$ cluster with all exo iodines (50% thermal ellipsoids). A C_{2h} symmetry results from a 2-fold axis that passes through I5 and K together with a mirror plane that contains atoms K, I4, and Zr2.

^aReference 3. ^bThe structure can be described as layered perpendicular to [001], this direction lying approximately from lower left to upper right in Figure 1. ^cSuperscripts on I refer to bridging functions (i = inner, edge bridging within cluster; a = outer or exo, bridgingbetween clusters).

metal, namely, Zr₆I₁₄K. The single-crystal X-ray diffraction results, electron microprobe analysis, magnetic susceptibility data, photoelectron spectroscopic measurements, and extended Hückel calculations on this novel cluster are reported here.

Sublimed KI, ZrI₄ (K:I, 1:14), and a large excess of reactorgrade Zr strips were sealed in a tantalum container and heated for 4-6 weeks in a 840-860 °C gradient. The air-sensitive product (10-20% yield) grew as clumps of shiny black gems on the zirconium in the hot end of the container. The clumps were visually separated from the remaining reaction products, α -ZrI₂, β -Z ZrI₃, and unreacted KI.

Pertinent X-ray data for two single crystals studied together with those for $CsZr_6I_{14}$ are available as supplementary material. Intensities for two octants were measured by using a four-circle automated diffractometer. The data were corrected for absorption effects by a method previously described.³ With $Zr_6I_{14}K$, a peak $(Z \sim 18)$ was observed in the center of the cluster in an electron density map (R = 14.0%) and a potassium atom was included in the model at that position. The refinement proceeded smoothly $(R = 4.5, R_w = 6.3\%)$ with all atoms refined anisotropically and with a potassium occupancy of 1.05(3). The position of cesium in $CsZr_6I_{14}$ within an iodine polyhedron was empty. Subsequent reactions also formed $Zr_6I_{14}K$ -type phases with somewhat smaller cell parameters, and refinement (R = 5.8, $R_w = 8.1\%$) of occupancy and anisotropic thermal parameters (but with K isotropic)

led to an X-ray stoichiometry of $Zr_6I_{14}K_{0.46(2)}$. The $Zr_6I_{14}K_x$ structure is isostructural with Nb₆Cl₁₄ and $Ta_6 I_{14}^{6,7}$ as well as $CsZr_6 I_{14}$ (excluding the Cs and K positions). A view of the isolated potassium cluster along with iodine atoms
