A Radical-Chain Mechanism for Dinuclear C-H Bond Formation

Robin T. Edidin and Jack R. Norton*

Contribution from the Department of Chemistry, Colorado State University, Fort Collins, Colorado 80523. Received July 8, 1985

Abstract: Both the formation of (Ph₃PAu)₂Os(CO)₄ from Ph₃PAuCH₃ and H₂Os(CO)₄ and the formation of (Ph₃PAu)Mn(CO)₅ from Ph₁PAuCH₃ and HMn(CO)₅ occur by radical-chain mechanisms. The chain carriers are Mn(CO)₅ and Os(H)(CO)₄, respectively, arising from hydrogen atom abstraction from the initial hydrides. Photolysis of a small amount of the appropriate dimer $(Mn_2(CO)_{10} \text{ or } H_2Os_2(CO)_8)$ generates the chain carrier and thus initiates the reaction. No such reaction occurs between Ph₃PAuCH₃ and HRe(CO)₅, even in the presence of substantial amounts of Re(CO)₅. The formation of H₂Os(CO)₃PPh₃ from Ph₃P and H₂Os(CO)₄ also occurs by a radical-chain mechanism with Os(H)(CO)₄ as the chain carrier, and the reactions of Ph_3PAuCH_3 and Ph_3P with $H_2Os(CO)_4$ can be simultaneously initiated.

After concluding that the reaction of Cp2ZrMe2 with HM- $(CO)_{3}Cp$ (M = Cr, Mo, W) (reaction 1) proceeded by a proton-transfer mechanism,¹ our attention was attracted by the briefly

$$Cp_2ZrMe_2 + HM(CO)_3Cp \xrightarrow{CH_3CN or}_{THF}CH_4 + Cp_2Zr M(CO)_2Cp (1)$$

reported (without specification of solvent or reaction conditions)² reaction of (Ph₃P)AuMe with HMn(CO)₅ (reaction 2). Although $(Ph_3P)AuMe + HMn(CO)_5 \rightarrow (Ph_3P)AuMn(CO)_5$ (2)

Stone and co-workers used HMn(CO)₅ in the course of a study of the reaction of (Ph₃P)AuCH₃ with strong acids, they noted that HMn(CO)₅ contained "only weakly protonic hydrogen",² and we considered a proton-transfer mechanism unlikely for reaction 2 for a variety of reasons. While HMn(CO)₅ is in fact an organometallic acid of moderate strength (its pK_a in acetonitrile is 15.2, in between that of HMo(CO)₃Cp and that of HW-(CO)₃Cp³), the Au-CH₃ bond is much less polar than the Zr-CH₃ bond in reaction 1; the Pauling electronegativity of Au (2.4) is approximately equal to that of C (2.5), while that of Zr is much less (1.4).⁴ We have therefore investigated the mechanism of the reaction of (Ph₃P)AuCH₃ with HMn(CO)₅ and with other carbonyl hydrides. We now report that these reactions proceed (if they proceed at all) by radical-chain mechanisms and are the first example of the operation of such mechanisms in intermolecular C-H bond-forming reactions.5-7

Results

Preliminary investigation confirmed that (Ph₃P)AuMe and $HMn(CO)_5$, in C₆D₆ at room temperature, gave the known (from the reaction of Mn(CO)5⁻ and Ph₃PAuCl)⁸ dinuclear mixed-metal

(5) A radical mechanism has been demonstrated for the elimination of p-CH₃OC₆H₄CH₃ from cis-p-CH₃OC₆H₄CH₂Mn(CO)₄L and cis-HMn-(CO)₄L in nondonor solvents, but the mechanism involves Mn-C bond homolysis rather than a chain process.⁶ Similarly, Bergman and Jones' have

proposed that the formation of toluene from $CpM_0(CO)_3CH_2C_6H_3$ and $HM_0(CO)_3Cp$ occurs by Mo-C bond homolysis. Homolysis is doubtless more

likely when, as in these two cases, benzyl radicals are formed.

complex $(Ph_3P)AuMn(CO)_5$ (1). Use of $H_2Os(CO)_4$ in place of $HMn(CO)_5$, in toluene at 35 °C, gave (reaction 3) methane and the trinuclear mixed-metal complex 2, also previously prepared by an alternate route $([Os(CO)_4]^2$ and 2 equiv of Ph₃PAuCl).⁹

The recently reported¹⁰ X-ray structure of 2 shows an unmistakable Au-Au interaction, with an Au-Au distance of 2.929 (1) Å; similar structures, with somewhat longer Au-Au distances, have been reported for the iron analogues of 2, (Ph₃PAu)₂Fe- $(CO)_4^{11}$ and $[(Ph_2PCH_2CH_2PPh_2)Au_2Fe(CO)_4]_2^{12}$

No toluene was found when reaction 3 was carried out in benzene (which would have formed some toluene if attacked by methyl radicals¹³), suggesting that the reaction either did not proceed by Au-C bond homolysis or that the resulting methyl radicals abstracted hydrogen atoms from H2Os(CO)4 more rapidly than they attacked benzene. In any case, the known¹⁴ mechanism of decomposition of Ph₃PAuCH₃ in decalin at 100 °C (rate-limiting loss of Ph₃P followed by rapid reaction with another molecule of Ph₃PAuCH₃) made facile Au-C bond homolysis at 35 °C extremely unlikely.

Our initial measurements of the kinetics of reaction 3, however, gave inconsistent results. Under pseudo-first-order conditions, with $[Ph_3PAuCH_3] = 0.074$ M, the rate of disappearance of $H_2Os(CO)_4$ varied from 1.3×10^{-4} to $<6.0 \times 10^{-6} s^{-1}$. Slower rates were observed when the reaction was carried out under argon than when it was carried out under nitrogen, an observation which suggested that the rate of the reaction was quite sensitive to small amounts of oxygen (argon, being heavier than nitrogen, is presumably more effective at excluding oxygen).

These results suggested that reaction 3 was occurring by a radical-chain mechanism induced by traces of oxygen.¹⁵⁻¹⁸ Indeed,

⁽⁹⁾ George, R. D.; Knox, S. A. R.; Stone, F. G. A. J. Chem. Soc., Dalton Trans. 1973, 972.

Figure 1. Absorbance (in 0.1-mm cells) at 2049 cm⁻¹ due to H₂Os(CO)₄ (about 1.5×10^{-3} M) in the presence of 0.074 M Ph₃PAuCH₃. In toluene under nitrogen (--), in benzene under nitrogen (---), and in toluene under argon ($-\bullet-\bullet$). AIBN was added when shown by **E**.

when a solution of Ph_3PAuCH_3 and $H_2Os(CO)_4$ in toluene was repeatedly frozen and degassed on a high vacuum line, and when the solution was sampled under argon with careful exclusion of air, no detectable reaction occurred at 35 °C. Addition of AIBN (10%-15% mole fraction of $H_2Os(CO)_4$) to carefully deoxygenated reaction mixtures resulted in a noticeable increase in the rate of the reaction, even at 35 °C (as shown in Figure 1). As AIBN is not a very efficient initiator at 35 °C,¹⁹ these reaction profiles suggested that reaction 3 was not only a radical-chain reaction but a very efficient one.

The most plausible chain carrier was the osmium-centered radical $HOs(CO)_4$ (3). Facile radical-chain substitution involving initial hydrogen atom abstraction and substitution on the resulting 17-electron species had already been established for other osmium hydrides, e.g., H(CH₃)Os(CO)₄¹⁷ and HOs(CO)₄Os(CO)₄CH₃²⁰ and such processes were familiar from the pioneering work of Brown and his research group on $HRe(CO)_5^{16,21}$ and $CpM(CO)_3H$ $(M = Mo \text{ and } W).^{21,22}$ We therefore examined Ph₃P substitution on $H_2Os(CO)_4$ (reaction 4), which seemed likely, by analogy with the mechanism established^{16,21} for Ph₃P substitution on HRe(CO)₅, to proceed by a radical-chain mechanism involving 3 as the chain carrier.

> $H_{2}Os(CO)_{4}$ + Ph₃P $\frac{C_{6}H_{6}}{H_{2}Os(CO)_{3}PPh_{3}}$ + CO (4)

There had been an early report²³ that reaction 4 gave 4 in 4 h at 80 °C in heptane; NMR and IR evidence unambiguously showed that 4 had the structure shown. The relatively mild conditions reported offered additional evidence against the only plausible nonradical mechanism, carbonyl dissociation; at 125.8 °C in mesitylene, the rate constant for carbonyl dissociation was known²⁴ to be 6.1×10^{-5} s⁻¹.

Addition of a small amount of AIBN to a benzene solution of 10:1 Ph₃P/H₂Os(CO)₄ permitted reaction 4 to occur at a rea-

(24) Evans, J.; Norton, J. R. J. Am. Chem. Soc. 1974, 96, 7577.

Figure 2. Absorbance (in 0.1-mm cells) at 2071 cm⁻¹ due to H₂Os(CO)₄ (---), and absorbance at 2081 cm⁻¹ due to $H_2Os(CO)_3PPh_3$ (4) (arising from a 10:1 Ph₃P/H₂Os(CO)₄ solution in benzene at 35 °C.

sonable rate even at 35 °C. Furthermore, the induction period observed when AIBN was not initially present, and the sudden acceleration of rate observed when it was added (Figure 2), provided clear evidence that a radical-chain mechanism was operating.

Reaction 4 thus occurred under conditions similar to those for reaction 3, an observation which suggested that they shared similar radical-chain mechanisms. We therefore carried out the experiment shown as reaction 5. Both NMR and IR showed that the

$$\begin{array}{c|c} Ph_{3}PAuCH_{3} \\ + \\ Ph_{3}P \end{array} + \begin{array}{c} H_{2}Os(CO)_{4} \\ \hline C_{6}H_{6}, 35 \ ^{\circ}C. \ AIBN \\ H_{2}Os(CO)_{3}PPh_{3} \end{array} + \begin{array}{c} (Ph_{3}PAu)_{2}Os(CO)_{4} \ (2) \\ + \\ H_{2}Os(CO)_{3}PPh_{3} \ (4) \end{array}$$

formation of 2 paralleled the formation of 4 and, therefore, that reactions 3 and 4 proceeded via a common chain carrier.

In order to determine whether or not the chain carrier was indeed $HOs(CO)_4$, we decided to generate the latter by photolysis of $H_2Os_2(CO)_8$. The primary photoprocess upon visible irradiation (300-500 nm) of such metal-metal-bonded dimers is metal-metal bond homolysis, yielding two metal-centered radicals.²⁵ For example, $\text{Re}_2(\text{CO})_{10}$ has a UV absorption at 313 nm ($\epsilon = 1.55$ × 10⁴ M⁻¹ cm⁻¹) which arises from a $\sigma \rightarrow \sigma^*$ transition;^{26,27} photolysis at 313 or 366 nm generates Re(CO)₅.²⁷ Time-resolved IR spectroscopy has recently allowed direct observation of .Mn-(CO)₅ (along with some $Mn_2(CO)_9$) after flash photolysis of $Mn_2(CO)_{10}$.²⁸ Irradiation of $H_2Os_2(CO)_8$, which shows a UV absorption at 286 nm with $\epsilon = 4.37 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$,²⁹ must therefore generate $HOs(CO)_4$ according to eq 6.

$$\begin{array}{c|c} H & H \\ \hline & \\ Os & \\ OC)_4 & Oc \end{array} \xrightarrow{h\nu} 2HOs(CO)_4 \tag{6}$$

Irradiation of solutions containing such metal-metal-bonded dimers (e.g., $\text{Re}_2(\text{CO})_{10}$,¹⁶ $[\text{CpW}(\text{CO})_3]_2^{22}$) was known to initiate a number of radical-chain reactions (e.g., $\text{Ph}_3\text{P} + \text{HRe}(\text{CO})_5 \rightarrow$ $HRe(CO)_4PPh_{3,1}^{16}Ph_3P + CpW(CO)_3H \rightarrow CpW(CO)_2$ $(PPh_3)H^{22}$). We therefore irradiated with Pyrex-filtered light a benzene solution of $H_2Os(CO)_4$, $H_2Os_2(CO)_8$ (10% of H_2Os_2 (CO)₄), and excess Ph₃PAuCH₃. (No reaction occurred under

⁽²⁹⁾ H₂Os(CO)₄, which lacks the Os–Os bond, shows λ_{max} at 225 nm and no significant absorption above 280 nm.

Figure 3. Absorbance (in 0.1-mm cells) at 2049 cm⁻¹ due to $H_2Os(CO)_4$ -), and absorbance at 2035 cm⁻¹ due to (Ph₃PAu)₂Os(CO)₄ (2) (---) arising from a solution originally 0.032 M in Ph₃PAuCH₃, 1.4×10^{-3} M in H₂Os(CO)₄, and 1.1×10^{-4} M in H₂Os₂(CO)₈. The solution was briefly (3 min) irradiated after 1 h as shown.

the same conditions without $H_2Os_2(CO)_8$.) As illustrated in Figure 3, 3 min of irradiation converted 80% of the starting material to product, although the same solution had shown virtually no reaction during an hour prior to irradiation. This dramatic increase

$$2(Ph_{3}P)AuMe + H_{2}Os(CO)_{4} \xrightarrow[10\% H_{2}Os_{2}(CO)_{8}]{} CH_{4} + (Ph_{3}PAu)_{2}Os(CO)_{4} (7)$$

in rate (the rate of the $H_2Os_2(CO)_8/h\nu$ reaction was at least 100 times faster than the maximum rate observed for reaction 3 under any other conditions) confirmed that HOs(CO)₄, or some species derived from it,^{30,31} was the chain carrier for reaction 3, and therefore for reaction 4 as well.

Radical-Chain Reactions of Ph₃PAuCH₃ with Other Hydrides. In the absence of initiator and with careful exclusion of air, reaction 2 (Ph₃PAuCH₃/HMn(CO)₅) occurred very slowly at ambient temperature (<5% in 22 h). However, photolysis for 3 min in the presence of 10% $Mn_2(CO)_{10}$ (known²⁵⁻²⁸ to give rise to \cdot Mn(CO)₅ radicals) caused the reaction to go to 53% completion. Photolysis of a 1:1:1 mixture of HMn(CO)₅, Ph₃PAuCH₃, and PPh₃ containing 10% Mn₂(CO)₁₀ (an experiment similar to

$$(Ph_{3}P)AuCH_{3} + HMn(CO)_{5} \xrightarrow[10\%]{n_{P}(CO)_{10}} CH_{4} + (Ph_{3}P)AuMn(CO)_{5} (8)$$

reaction 5, but with photochemical rather than thermal initiation) showed the simultaneous formation of 1 and HMn(CO)₄PPh₃.

(F

$$\begin{array}{c|c} {}^{h_{3}P)AuCH_{3}} \\ + \\ Ph_{3}P \end{array} + \begin{array}{c} {}^{HMn(CO)_{5}} \\ \hline \\ C_{6}D_{6}.10\% Mn_{2}(CO)_{10}, \hbar \nu \end{array} + \begin{array}{c} (Ph_{3}P)AuMn(CO)_{5} (1) \\ + \\ HMn(CO)_{4}PPh_{3} \end{array}$$

In view of the established¹⁶ radical-chain nature (with ·Mn(CO)₅ as the chain carrier) of $Ph_3P + HMn(CO)_5 \rightarrow HMn(CO)_4PPh_3$, this result implied that reaction 2 proceeded by a radical-chain mechanism with $Mn(CO)_5$ as the chain carrier. The fact that the $HMn(CO)_4PPh_3/1$ ratio at the end of experiment 9 (which had contained insufficient $HMn(CO)_5$ to react completely with both substrates) was 9:1 suggested that $\cdot Mn(CO)_5$ was more reactive toward Ph₃P than toward (Ph₃P)AuCH₃.

To our surprise, HRe(CO)₅ proved completely unreactive toward Ph₃PAuCH₃, despite the fact that the expected product 5 had been prepared from $[Re(CO)_5]^-$ and $Ph_3PAuCl.^{32}$ No

amount of added AIBN (even a stoichiometric amount at 90 °C!) would initiate the reaction, and photolysis in the presence of added $Re_2(CO)_{10}$ also had no effect. Photolysis in the presence of $^2/_3$ of an equivalent of Ph₃P gave immediate formation of HRe- $(CO)_4PPh_3$ —demonstrating that $\cdot Re(CO)_5$ radicals had been generated—but left the Ph₃PAuCH₃ unchanged.

Discussion

Radical-chain mechanisms are well-established for phosphine substitution on metal carbonyl hydrides, particularly HRe-(CO)₅,^{16,21} and it is hardly surprising to find one operating for phosphine substitution on the closely related $H_2Os(CO)_4$. Assuming that the chain carrier is HOs(CO)₄ itself,³⁰ reaction 4 must proceed by the mechanism in Scheme I, parallel to the known mechanism for $Ph_3P + HRe(CO)_5 \rightarrow HRe(CO)_4PPh_3$ with •Re(CO)₅ as a chain carrier. In view of the good evidence^{30,31} that the reaction of $Re(CO)_5$ and Ph_3P is associative, it is likely that the reaction of $HOs(CO)_4$ with Ph_3P is associative.

In contrast, there is no known mechanism which immediately suggests a parallel mechanism for reactions 2 and 3. A radical-chain process has, however, been proposed for another reaction of LAuMe (reaction 12).³³ One mechanism suggested, Scheme

$$LAuCH_3 + HSPh \rightarrow LAuSPh + CH_4$$
(12)

$$(L = Me_3P, MePh_2P, and Ph_3P)$$

II, involves displacement of a methyl radical from $LAuCH_3$ by attack of SPh, either by a concerted or a stepwise S_H^2 mechanism. The other mechanism suggested, Scheme III, involves hydrogen atom abstraction by a gold-centered radical after SPh attack on

⁽³⁰⁾ In view of the evidence showing that neither $\cdot Mn(CO)_5^{28}$ nor $\cdot Re-(CO)_5^{31}$ readily dissociates CO, it seems likely that the chain carrier for reactions 3 and 4 is HOs(CO)₄ itself. (31) Fox, A.; Malito, J.; Poč, A. J. Chem. Soc., Chem. Commun. 1981, 1952.

LAuCH₃; the resulting gold(III) hydridomethyl complex then eliminates methane, leaving LAuSPh.

If one replaces HSPh by $H_2Os(CO)_4$ and \cdot SPh by $HOs(CO)_4$, Schemes II and III give rise to Schemes IV and V for reacion 3. As in Scheme II, the second step of Scheme IV may be either a concerted or a stepwise S_H^2 reaction.

Both Schemes IV and V involve the same chain carrier, 3, as Scheme I-as required by the results of the coinitiation experiment. In both Schemes IV and V, the second hydrogen in $H_2O_s(CO)_4$ must react rapidly with a second (Ph₃P)AuCH₃ in order to account for the fact that no spectroscopically observable intermediate builds up. It is reasonable to suppose that this second methane elimination $(Ph_3PAuOs(H)(CO)_4 + Ph_3PAuCH_3 \rightarrow$ CH_4 + $(Ph_3PAu)_2Os(CO)_4$) also occurs by a radical-chain mechanism, but it is not at all clear why it is faster than the first methane elimination. An Au-Au interaction, of the sort seen in the X-ray structure of the product 2, may be involved. In any case, the structural and electronic analogy between H and Ph₃PAu³⁴ makes it reasonable for hydrogen atom abstraction from the presumed intermediate $Ph_3PAuOs(H)(CO)_4$ to be as fast as abstraction from $H_2Os(CO)_4$.

Scheme V may be regarded as a radical-chain oxidative addition of an H-Os bond of H₂Os(CO)₄ across the Au in Ph₃PAuCH₃. As such, it finds precedent in the well-established³⁵ radical-chain oxidative additions of alkyl halides to complexes containing lowvalent transition metals. However, the result of the H-Os addition in Scheme V, and the H-S addition proposed by Puddephatt³³ in Scheme III, is the formation of an Au-H bond. Such bonds

are generally believed to be weak (no mononuclear gold hydrides are known, although hydride bridges between gold and other metals have recently been reported³⁶), and thus their formation by H. transfer from H-Os and H-S bonds is an unattractive feature of Schemes III and V.

Of course, Schemes II and IV have their own unattractive feature, the formation of methyl radicals from LAuMe and SPh or $HOs(CO)_4$ in an S_H2 reaction; the results given above (no formation of toluene in benzene) offer no evidence in support of the presence of methyl radicals in reaction 3.37,38 Given the present lack of reliable thermochemical information for organometallic systems, it is not possible to make a definitive choice between Schemes IV and V-or between these and any other radical-chain mechanism involving HOs(CO)₄. On balance, we prefer Scheme V-the simplest explanation for our observations, and the one best supported by analogy. Its corollary for reaction 2, Scheme VI, offers a relatively straightforward explanation of the fact that $HRe(CO)_5$ does not react and $HMn(CO)_5$ does. It is generally believed³⁹⁻⁴¹ that the Re-H bond is stronger than the Mn-H one, and it is possible that the Re-H bond is stronger than the Os-H one. (Rhenium shows an exceptional ability to form stable polyhydrides, e.g., $\text{ReH}_9^{2^-,4^2}$ and $\text{HRe}(\text{CO})_5$ is a weaker acid than $\text{H}_2\text{Os}(\text{CO})_4$.^{3c}) An Re-to-Au H· transfer may thus be endothermic when the corresponding Mn-to-Au and Os-to-Au transfers are exothermic.

Overall, it is clear that reactions 2 and 3 proceed by radicalchain mechanisms and that the chain carriers are $Mn(CO)_5$ and HOs(CO)₄, respectively. Such radical-chain mechanisms for intermolecular C-H bond formation, while not previously reported, are likely to prove common, particularly when the alkyl complex can readily undergo oxidative addition. The formation of $M_2Pt(CO)_{12}$ in reaction 13⁴³ is almost certainly another example.

$$Me_{2}Pt(cyclooctadiene) + 2HM(CO)_{5} \xrightarrow{CO} 2CH_{4} + M_{2}Pt(CO)_{12} (13)$$

Experimental Section

General. IR spectra were obtained on a Beckman IR-12 spectrometer. NMR kinetics measurements were made on a JEOL FX-100 FT spectrometer. UV-visible spectra were obtained on either a Cary 17 spectrophotometer or a Varian 620 spectrophotometer. Unless otherwise

specified, all operations were carried out under a nitrogen atmosphere by using standard vacuum-line or inert atmosphere techniques. Nitrogen was purified by passage through BTS catalyst (BASF) and 3-Å molecular sieves.

Toluene was distilled under nitrogen from sodium and benzophenone. Benzene used for kinetics and benzene- d_6 used for NMR studies were dried over P4O10, frozen, and degassed at least 3 times and transferred under vacuum either directly into a kinetics vial or into a storage vessel.

Infrared extinction coefficients for carbonyl bands of H₂Os(CO)₄, $H_2Os(CO)_3PPh_3$ (4), and cis-[PPh_3Au]_2Os(CO)_4 (2), determined from the absorbance of solutions of known concentration, were as follows: $H_2Os(CO)_4$, 6.1 × 10² (2049 cm⁻¹); 4, 2.4 × 10² (2081 cm⁻¹), 2.9 × 10² $(2023 \text{ cm}^{-1}); 2, 2.8 \times 10^2 (2035 \text{ cm}^{-1}) \text{ cm}^{-1} \text{ M}^{-1}$

Compounds. The compounds $H_2Os(CO)_4$,¹⁷ PPh₃AuCH₃,⁴⁴ and $HMn(CO)_5^{45}$ (M = Mn and Re) were prepared by published methods. Triphenylphosphinemethylgold(I) was recrystallized at least twice from CH_2Cl_2 /hexane immediately before each kinetics run. $H_2Os(CO)_4$ was purified on a vacuum line by passage through a U-tube packed with P4O10 interspersed among glass beads and was stored under vacuum at -30 °C.

Preparation of $H_2Os_2(CO)_8$. A 24-cm long vacuum line reaction bulb was charged with $H_2Os(CO)_4$ (132.3 mg, 0.435 mmol) and was placed under 10 mmHg CO pressure. A 1-in. span in the middle of the bulb was heated with nichrome wire, while the lower half of the bulb was immersed in ice water. After 20 min, droplets of a clear viscous liquid (presumably $H_2Os_2(CO)_8$) appeared on the cold portion of the surface directly below the nichrome heating coil. The process was continued for 12 h, after which a copious amount of viscous liquid and yellow solid appeared to be present. Ambient temperature volatiles were removed in vacuo, and under nitrogen, the remaining materials were dissolved in 6 mL of hexane. The resultant solution was transferred to a 25-mL round-bottom flask, the solvent was removed in vacuo, and the H₂Os₂-(CO)8 remaining was purified by bulb-to-bulb evaporative distillation at 40 °C: yield (based on $H_2OS(CO)_4$) 21%. The infrared spectrum was consistent with that reported in the literature.⁴⁶ The UV spectrum in decane showed a peak at 286 nm, $\epsilon = 4.37 \times 10^3$ cm⁻¹ M⁻¹, and one at 231 nm, $\epsilon = 3.45 \times 10^3 \text{ cm}^{-1} \text{ M}^{-1}$.

Kinetics of Ph₃PAuCH₃ + H₂Os(CO)₄. General. All kinetic and other studies of the Ph₃PAuCH₃/H₂Os(CO)₄ system were performed at 35 °C. Calcium fluoride (1 mm) or KBr (0.1 mm) cells used for infrared measurements were purged with nitrogen or argon prior to each measurement. The carbonyl stretches at 2071 and 2049 cm⁻¹ of the reactant cis-H₂Os(CO)₄ were easily monitored, as was that of the product, 2, which falls at 2035 cm⁻¹. All reactions were carried out in a 25-mL vacuum-line reaction bulb equipped with a Teflon stopcock.

In a typical run, a bulb was charged with Ph₃PAuCH₃ (0.074 M) and toluene, the solution was frozen and degassed several times, and H2Os-(CO)₄ (3 × 10⁻³ to 10⁻² M) was transferred in under vacuum. The reaction mixture was sampled by quenching the solution at 0 °C and removing an aliquot by syringe under a heavy flow of nitrogen or argon. The product cis-[PPh₃Au]₂Os(CO)₄, 2, was identified by its IR, reported in the literature.⁹ Apparent rate constants varied from 1.3×10^{-4} to <6.0 \times 10⁻⁶ s⁻¹ (no detectable reaction).

 $Ph_3PAuCH_3 + H_2Os(CO)_4$ with Added Initiator (AIBN). A solution of Ph₃PAuCH₃ (0.074–0.073 M) and H₂Os(CO)₄ (about 1.5×10^{-3} M) was prepared as above, and some initial data points were taken. AIBN (approximately 15 mol % of the $H_2Os(CO)_4$) was then added either as a solid or as an aliquot (i.e., 0.1 mL of a 0.015 M solution in toluene or benzene) under a heavy stream of nitrogen. Monitoring at 2049 cm⁻¹ was then continued as described above. The results are shown in Figure s⁻¹. 1. After initiation, the apparent rate constant was about 7×10^{-5}

PPh₃ Substitution of $H_2Os(CO)_4$. cis-Dihydridotetracarbonyl-osmium(II), (0.88 mg, 2.90×10^{-3} mmol) was transferred in vacuo to a standard vacuum-line reaction bulb containing PPh₃ (7.8 mg, 2.98 \times 10^{-2} mmol), AIBN (1.0 mg, 6.0 × 10^{-3} mmol), and benzene (2 mL) and the resultant solution frozen and degassed several times. The reaction was then sampled at appropriate intervals. Spectroscopic data for the product $H_2Os(CO)_4PPh_3$ (4) agreed with that given in the literature.²³ Infrared carbonyl bands of the disubstituted product $H_2Os(CO)_2(PPh_3)_2$, expected at 2014 (vs) and 1990 cm⁻¹ (vs),⁴⁷ were not observed.

Ph₃PAuCH₃/PPh₃ Simultaneous Reaction with cis-H₂Os(CO)₄ (IR Study). A standard vacuum-line reaction bulb was charged with Ph₃PAuCH₃ (2.3 mg, 4.85 \times 10⁻³ mmol), PPh₃ (1.4 mg, 5.34 \times 10⁻³ mmol), AIBN (0.1 mg, 6.7×10^{-4} mmol), *cis*-H₂Os(CO)₄ (1.46 mg, 4.80 \times 10⁻³ mmol), and benzene (4 mL). The resultant solution was frozen and degassed several times. After 3 days, 4 was identified by the appearance of its infrared bands at 2081 and 2023 cm^{-1,23} The other product, 2, was similarly identified by its infrared carbonyl band at 2035 cm⁻¹.9 The ratio of products, calculated from the relative absorbances of the 2081-cm⁻¹ band of $H_2Os(CO)_3PPh_3$ and the 2035-cm⁻¹ band of cis-[PPh₃Au]₂Os(CO)₄, was found to be 60:40 for 4:2.

Ph₃PAuCH₃/PPh₃ Competition for cis-H₂Os(CO)₄ (NMR Study) An NMR tube was charged with Ph_3PAuCH_3 (23 mg, 4.85 × 10⁻² mmol), PPh₃ (12.5 mg, 4.77×10^{-2} mmol), and AIBN (1.1 mg, $6.55 \times$ 10^{-3} mmol). Benzene-d₆ (0.3 mL) and cis-H₂Os(CO)₄ (15 mg, 4.93 × 10^{-2} mmol) were transferred in under vacuum, and the tube was sealed. The initial spectrum showed a small amount of reaction (<5%) between PPh₃, Ph₃PAuCH₃, and cis-H₂Os(CO)₄. The tube was heated at 35 °C for 2 h after which a decrease in all reactants was observed. A peak at δ 0.18 due to methane was now present, in addition to a doublet at δ -7.51 (J = 24 Hz) due to H₂Os(CO)₃PPh₃ (indicating an all-cis geometry).²³ The ratio of products, calculated from the decrease in the integral of the Ph₃PAuCH₃ methyl peak and the increase in the integral for the H₂Os(CO)₄PPh₃ doublet, was found to be 62:38 for 4:2, in good agreement with that found in the analogous IR experiment (above).

Initiation of $H_2Os(CO)_4 + Ph_3PAuCH_3$ by $H_2Os_2(CO)_8$ Photolysis. A standard vacuum-line reaction bulb was charged with Ph₃PAuCH₃ (30 mg, 6.33×10^{-2} mmol), *cis*-H₂Os(CO)₄ (0.85 mg, 2.80×10^{-3} mmol), $H_2Os_2(CO)_8$ (0.13 mg, 2.16 × 10⁻⁴ mmol), and benzene (2 mL). The resultant solution was shielded from light during the initial reaction and IR sampling period and then irradiated with a 450-W mercury lamp (Pyrex-filtered light) for 3 min, resulting in a golden-yellow solution (as expected for 2). Infrared measurements were resumed immediately after irradiation. The extent of product formation after photolysis (80% conversion to product) was determined from the intensity of the product peak at 2035 cm⁻¹. The concentrations of $H_2Os(CO)_4$ and 2 as a function of time are shown in Figure 3. A similar reaction without $H_2Os_2(CO)_8$ (28 mg of Ph₃PAuCH₃ and 1.88 mg of cis-H₂Os(CO)₄ in 1.9 mL of toluene) showed no reaction when photolyzed for 5 min in the same apparatus.

Attempted Initiation of HRe(CO)₅ + Ph_3PAuCH_3 with AIBN. In a typical experiment, a NMR tube was charged with Ph₃PAuCH₃ (about 0.04 mmol) and AIBN, and under vacuum, solvent and HRe(CO)₅ (about 0.04 mmol) were transferred into the tube. No evidence of reaction was seen after 36 h, nor was it possible to induce thermal initiation by heating a stoichiometric amount of AIBN and reactants to 90 °C.

Reaction of Ph₃PAuCH₃, PPh₃, and HRe(CO)₅ Initiated by Photolysis of $Re_2(CO)_{10}$. An NMR tube containing Ph_3PAuCH_3 (25 mg, 5.27 × 10^{-2} mmol), HRe(CO)₅ (17.4 mg, 5.32 × 10^{-2} mmol), Re₂(CO)₁₀ (3 mg, 4.60×10^{-3} mmol), and benzene- d_6 (0.3 mL) was prepared under vacuum, and the NMR spectrum (δ 10 to -10) before and after photolysis (3 min, 450-W UV broad-band lamp, Pyrex-filtered) showed only starting materials. Triphenylphosphine (9.0 mg, 3.72×10^{-2} mmol) was then added under nitrogen to the contents of the tube. The methyl peak of Ph₃PAuCH₃ now appeared as a singlet at δ 1.10 (due to rapid exchange between free phosphine and the phosphine on Ph₃PAuCH₃). After photolysis, the methyl doublet of Ph₃PAuCH₃ (δ 1.10, $J_{PH} = 8$ Hz)⁴⁴ had now reappeared, the doublet (δ -4.96, $J_{PH} = 22$ Hz) due to $HRe(CO)_4PPh_3^{48}$ was present in addition to the singlet of $HRe(CO)_5$ (δ -5.60).

Reaction of HMn(CO)₅ + Ph₃PAuCH₃. An NMR tube containing Ph_3PAuCH_3 (28 mg, 5.91 × 10⁻² mmol), $HMn(CO)_5$ (15.6 mg, 0.0796 mmol), and benzene- d_6 (0.3 mL) was prepared and sealed under vacuum. The reaction was maintained at ambient temperature and monitored by ¹H NMR over a 22-h period. At this time, very little (CO)₅MnAuPPh₃ (1) had formed (<5% by NMR integration) and a small amount of starting material decomposition had occurred.

Reaction of HMn(CO)₅ + Ph₃PAuCH₃ Initiated by Photolysis of $Mn_2(CO)_{10}$. An NMR tube containing HMn(CO)₅ (12 mg, 6.12 × 10⁻² mmol), Ph₃PAuCH₃ (27 mg, 5.70 × 10⁻² mmol), Mn₂(CO)₁₀ (2 mg, 5.13 \times 10⁻³ mmol), and benzene-d₆ (0.3 mL) was prepared and sealed under vacuum. The ¹H NMR spectrum (δ 10 to -10) before photolysis showed only starting materials. Photolysis for 3 min with a 450-W broad-band UV lamp (Pyrex-filtered) resulted in the formation of (CO)₅MnAuPPh₃ (53%) as determined by the decrease in NMR resonances due to Ph₃PAuCH₃ (δ 1.10, d, J_{PH} = 9 Hz) and HMn(CO)₅ (δ -7.42, s) relative to the phenyl region. A peak at δ 0.18 due to methane was also present. The presence of (CO)₅MnAuPPh₃ (1) was verified by an IR (CCl₄: 1962 (s), 2057 (s) cm⁻¹) in agreement with that reported in the literature.⁸

Photolysis of $HMn(CO)_5 + Ph_3PAuCH_3 + PPh_3$ in the Presence of **10%** $Mn_2(CO)_{10}$. An NMR tube containing HMn(CO)₅ (6 mg, 3.06 × 10⁻² mmol), Ph₃PAuCH₃ (15 mg, 3.16 × 10⁻² mmol), PPh₃ (7.2 mg, 2.75

 \times 10⁻² mmol), Mn₂(CO)₁₀ (2 mg, 5.13 \times 10⁻³ mmol), and 0.2 mL of benzene- d_6 was prepared and sealed under vacuum. The initial NMR prior to photolysis showed that some reaction (about 63%) had occurred between HMn(CO)₅ and PPh₃ to give HMn(CO)₄PPh₃ (δ -6.9, d, J_{PH} = 35 Hz).⁴⁹ The tube, shielded from light during the initial reaction period, was then photolyzed for 2 min (see above for details). A decrease in both Ph₃PAuCH₃ methyl and HMn(CO)₅ hydride integrals relative to the phenyl region integration (which should remain constant) was observed; the 1/HMn(CO)₄PPh₃ ratio thereby indicated was 1:9. A small peak at δ 0.18 due to methane was also now present. The product

Received August 23, 1985

Abstract: The reaction of $(n-Bu_4N)_2Re_2X_8$ (X = Cl or Br) with PMe₃ gives high yields of the triply bonded complexes $Re_2X_4(PMe_3)_4$. These compounds are oxidized by NOPF₆ to give paramagnetic $[Re_2X_4(PMe_3)_4]PF_6$, and the chloro derivative reacts with $Ph_2PCH_2PPh_2$ (dppm) and $Ph_2PNHPPh_2$ (dppa) to give $Re_2Cl_4(PMe_3)_2(dppm)$ and $Re_2Cl_4(PMe_3)_2(dppm)$, respectively. NMR spectroscopy (1H and 31P(1H)) shows that the latter complexes possess fairly symmetrical structures in which the PMe3 ligands are in cis dispositions with respect to the bridging dppm and dppa ligands. The volatility of Re₂Cl₄(PMe₃)₄ has permitted the measurement of its gas-phase photoelectron spectrum which accords with this compound possessing a $\sigma^2 \pi^4 \delta^2 \delta^{*2}$ configuration. The δ^* ionization band is slightly narrower than the δ ionization band and occurs at about 0.9 eV lower binding energy. The π ionization gives evidence of spin-orbit splitting as expected for the heavy-atom rhenium character. An ionization assigned to removal of an electron from the valence σ orbital is observed at a binding energy 1 eV higher than the π ionization. Comparison of these ionizations with those of the corresponding W₂Cl₄(PMe₃)₄ ($\sigma^2 \pi^4 \delta^2$) complex is especially informative. In particular, these observations support a strong interaction between the valence σ density on one metal atom and the core density on the neighboring metal atom in these complexes.

Complexes with close metal-metal interactions offer special opportunities to investigate the factors that influence metal-metal bonding, electronic structure, and reactivity.² Quadruply bonded complexes, which are derived from d⁴-d⁴ metal interactions and have the $\sigma^2 \pi^4 \delta^2$ configuration, are especially interesting because they provide occupied orbitals with each symmetry type of metal-metal interaction— σ , π , and δ . Also interesting are species which are related by either the addition or removal of electrons from the $\sigma^2 \pi^4 \delta^2$ configuration. In particular, "electron-poor" metal-metal triple bonds derived from d^3 - d^3 complexes with $\sigma^2 \pi^4$ configurations, and "electron-rich" metal-metal triple bonds derived from d⁵-d⁵ complexes with $\sigma^2 \pi^4 \delta^2 \delta^{*2}$ configurations,² serve to expand our knowledge of the range of metal-metal interactions.

Valence photoelectron spectroscopy (PES) has proven to be extremely valuable in providing insight into the electronic in-teractions in metal-metal bonds, particularly for the quadruple³⁻⁷

and electron-poor triple^{8,9} metal-metal bonds. Nonetheless, important questions remain concerning the nature of the δ -ionized
