modynamics of the return electron transfer. An excellent correlation is observed in the present work presumably because, unlike previous work, the compounds studied are similar in structure and dimensions and do not undergo significant chemical reactions either within or outside the geminate radical pair and because accurate redox parameters were obtained.

## Rhodium $\mu$-Amido and $\mu$-Imido A-Frame Complexes: Tautomeric Equilibria with a Deprotonated Bis(diphenylphosphino)methane Ligand ${ }^{1}$

Paul R. Sharp* and Yuan-Wen Ge

Department of Chemistry University of Missouri-Columbia Columbia, Missouri 65211

Received February 27, 1987
Molecular A-frame complexes ${ }^{2}$ are one of the larger classes of bimetallic late-transition-metal complexes. While a large number of apex ligands have been incorporated, apex oxo, imido, and amido ligands are unknown. 3,4 The majority of A-frame complexes are based on the bis(diphenylphosphino)methane (dppm) ligand and usually contain the metals $\mathrm{Pt}, \mathrm{Pd}, \mathrm{Rh}$, or Ir. ${ }^{3.4 \mathrm{a}}$ Since we are interested in preparing $\mu$-oxo and $\mu$-imido complexes of these metals as models for late-transition-metal surface oxides, we began working on expanding the A-frame class to include complexes with these apex ligands. ${ }^{1}$ During this work we discovered the first examples of A-frame complexes containing a deprotonated dppm (bis(diphenylphosphino)methanide or dppmH) ligand and at least two examples where the dppm ligand is involved in a unique tautomeric equilibrium. Although dppm- H ligands have been previously observed, the complexes have been monomers, ${ }^{5}$ dimers with non-A-frame structures, ${ }^{6}$ or clusters. ${ }^{7}$ Our results show that the dppm-H ligand can support the A-frame structure. In addition, we have the first examples of A-frame complexes with bridging amido and imido ligands.

Figure 1. ORTEP view of $\mathrm{Rh}_{2}(\mu-\mathrm{NHMe})(\mathrm{CO})_{2}(\mu-\mathrm{dppm})(\mu-\mathrm{dppm}-\mathrm{H})$ (1a) $50 \%$ probability ellipsoids. Phenyl rings are omitted for clarity. Selected distances ( $\AA$ ) and angles (deg): P1-C3, 1.738 (8); P2-C3, 1.736 (8); P3-C4, 1.837 (7); P4-C4, 1.851 (7); C3-H1, 0.80 (9); Rh1-N, 2.107 (6); Rh2-N, 2.091 (5); N-HN, 1.09 (9); HN-C3, 2.23; P1-C3-P2, 119.3 (4); P1-C3-H1, 119 (7); P2-C3-H1, 115 (7); Rh1-N-Rh2, 94.4 (2); $\mathrm{Rh}^{2} \mathrm{~N}-\mathrm{CME}, 121.0$ (5); Rh2-N-CME, 127.5 (5); RH1-N-HN, 116 (4); Rh2-N-HN, 103 (4); CME-N-HN, 96 (4); N-HN-C3, 128 (4).

Treating yellow $\mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{CO})_{2}(\mu \text {-dppm })_{2}{ }^{8}$ with 2 equiv of LiNHR in ether gives a single orange product (1a) when $\mathrm{R}=$ Me (eq 1). Spectroscopic ${ }^{9}$ and X-ray ${ }^{11}$ data show 1a to be a

$$
\begin{array}{r}
\mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{CO})_{2}(\mu-\mathrm{dppm})_{2}+2 \mathrm{LiNHR} \xrightarrow{-2 \mathrm{LiCl}} \\
\mathrm{Rh}_{2}(\mu-\mathrm{NHR})(\mathrm{CO})_{2}(\mu-\mathrm{dppm})(\mu-\mathrm{dppm}-\mathrm{H})+ \\
\mathbf{1 a}, \mathrm{R}=\mathrm{Me} \\
\mathbf{1 b}, \mathrm{R}=\mathrm{Ph} \\
\mathbf{1 c}, \mathrm{R}=p-\mathrm{MePh} \\
\mathrm{R} \mathrm{~h}_{2}(\mu-\mathrm{NR})(\mathrm{CO})_{2}(\mu-\mathrm{dppm})_{2}(1) \\
\mathbf{2 b}, \mathrm{R}=\mathrm{Ph} \\
\mathbf{2 c}, \mathrm{R}=p-\mathrm{MePh}
\end{array}
$$

$\mu$-methylamido A-frame complex with a dppm-H ligand. A view of the molecular structure is shown in Figure 1.

When $\mathrm{R}=\mathrm{Ph}$ or $p$-MePh a mixture of two products (eq $1, \mathbf{1 b}$ and $\mathbf{2 b}$ for $\mathrm{R}=\mathrm{Ph}, \mathbf{1} \mathbf{c}$ and $\mathbf{2 c}$ for $\mathrm{R}=\mathrm{p}-\mathrm{MePh}$ ) is obtained as shown by IR. ${ }^{12}$ Experiments on the slower NMR time scale show that the two products are in rapid equilibrium, a slow exchange

[^0]
## Scheme I

( $\mathbf{a}, \mathrm{R}=\mathrm{Me} ; \mathrm{b}, \mathrm{R}=\mathrm{Ph}: \mathrm{c}, \mathrm{R}=\mathrm{p}$-MePh)
spectrum only being obtained at $-80^{\circ} \mathrm{C}\left(\mathrm{R}=p-\mathrm{MePh}, \Delta G^{\ddagger} \sim\right.$ $40 \mathrm{~kJ} / \mathrm{mol}){ }^{12}$ A structure similar to $\mathbf{1 a}$ is assigned to $\mathbf{1 b}, \mathbf{c}$ based on the similarity of the spectroscopic data. The spectroscopic data for $\mathbf{2 b}, \mathbf{c}$ are very similar to the data for $\mathrm{Rh}_{2}(\mu-\mathrm{S})(\mathrm{CO})_{2}(\mu-\mathrm{dppm})_{2}{ }^{2}$ and $\mathrm{Rh}_{2}(\mu-\mathrm{O})(\mathrm{CO})_{2}(\mu-\mathrm{dppm})_{2} \cdot \mathrm{LiBF}_{4} \cdot{ }^{1}$ We therefore formulate these products as the imido complexes $\mathrm{Rh}_{2}(\mu-\mathrm{NR})(\mathrm{CO})_{2}(\mu-$ $\mathrm{dppm})_{2}, \mathbf{2 b}(\mathrm{R}=\mathrm{Ph})$ and $\mathbf{2 c}(\mathrm{R}=p-\mathrm{MePh})$. Thus, $\mathbf{1}$ and $\mathbf{2}$ are tautomers in a tautomeric equilibrium (Scheme I). ${ }^{13}$ Although 1a is apparently not in equilibrium with its tautomer, at least on the NMR time scale (NMR spectra are invariant from -60 to $100^{\circ} \mathrm{C}$ ), the structure of 1 a does show how well the hydrogen (HN) is positioned for the shift needed to interconvert the tautomers (Figure 1). Indeed, HN is within hydrogen bonding distance of the methanide carbon, C3.

A likely reaction pathway for the formation of $\mathbf{1}$ and $\mathbf{2}$ is shown in Scheme I. Protonation of $\mathbf{1 a}$ or the equilibrium mixtures $\mathbf{1 b} / \mathbf{2 b}$ or $\mathbf{1 c} / \mathbf{2 c}$ gives the proposed intermediate, $\mathbf{3 a}, \mathbf{3 b}$, or $\mathbf{3 c}{ }^{14}$ (eq 2). The protonation is reversed upon addition of LiNHR.
$\mathbf{1 a}$ or $\mathbf{1 b} / \mathbf{2 b}$ or $\mathbf{1 c} / \mathbf{2 c} \underset{\underset{\text { LiNHR }}{ }}{\mathrm{H}^{+}}$

$$
\begin{gather*}
{\left[\mathrm{Rh}_{2}(\mu-\mathrm{NHR})(\mathrm{CO})_{2}(\mu-\mathrm{dppm})_{2}\right]^{+}}  \tag{2}\\
3 \mathbf{a}, \mathrm{R}=\mathrm{Me} \\
3 \mathrm{~b}, \mathrm{R}=\mathrm{Ph} \\
3 \mathbf{c}, \mathrm{R}=p-\mathrm{MePh}
\end{gather*}
$$

[^1]In contrast to $3 \mathrm{a}-\mathrm{c}$ the isoelectronic complexes $\left[\mathrm{M}_{2}(\mu-\mathrm{OH})\right.$ $\left.(\mathrm{CO})_{2}(\mu \text {-dppm })_{2}\right]^{+}\left(\mathrm{M}=\mathrm{Rh}^{15}\right.$ and $\left.\mathrm{Ir}^{16}\right)$ are deprotonated solely at the bridging OH ligand and not at a dppm ligand. ${ }^{1}$ While this may be due solely to the difference in acidity of the OH and NHR protons, the incorporation of $\mathrm{Li}^{+}$into the OH deprotonation product, $\mathrm{M}_{2}(\mu-\mathrm{O})(\mathrm{CO})_{2}(\mu \text {-dppm })_{2} \cdot \mathrm{LiBF}_{4}$ (most likely by coordination to the $\mu$-oxo ligand), complicates comparisons. The presence of the imido complex when $\mathrm{R}=\mathrm{Ph}(2 \mathrm{~b})$ or $p-\mathrm{MePh}$ (2c) but not when $\mathrm{R}=$ Me reflects the greater acidity of the amido group in 3b and $\mathbf{3 c}$ on replacing the methyl group in 3a with electron-withdrawing phenyl groups. This effect is further illustrated by the ratio of the tautomers (IR, $22^{\circ} \mathrm{C}$ ) which increases on going from $\mathrm{R}=\mathrm{Ph}(\mathbf{1 b}: \mathbf{2 b} \sim 1: 3)$ to less electron withdrawing $\mathrm{R}=p-\mathrm{MePh}(\mathbf{1 c}: \mathbf{2 c} \sim 1: 1)$.
Preliminary work on the reaction chemistry of $\mathbf{1}$ and $\mathbf{2}$ shows facile insertion of CO into the $\mathrm{Rh}-\mathrm{N}$ bond. Details of this work will be reported in a forthcoming publication.

Acknowledgment. We acknowledge the donors of the Petroleum Research Fund, administered by the American Chemical Society, the Research Corporation, and the UMC Research Council for support of this work and Johnson Matthey for a loan of $\mathrm{RhCl}_{3}$. The National Science Foundation provided a portion of the funds for the purchase of the x-ray (CHE-7820347) and NMR (PCM8115599 ) equipment. We thank G. Wei and Dr. R. Taylor for some of the NMR experiments.
