complexation/fusion behavior of these same carboranes. $6,7,11,12$ Thus, the more sterically hindered species, which exhibit slow deprotonation, similarly are the most sluggish toward formation of ( $\left.\mathrm{RR}^{\prime} \mathrm{C}_{2} \mathrm{~B}_{4} \mathrm{H}_{4}\right)_{2} \mathrm{FeH}_{2}$ complexes and conversion of the latter to $\mathrm{R}_{2} \mathrm{R}^{\prime} \mathrm{C}_{4} \mathrm{~B}_{8} \mathrm{H}_{8}$. Indeed, when R and $\mathrm{R}^{\prime}$ are both very large (e.g., indenylmethyl, fluorenylmethyl, or ( CO$)_{3} \mathrm{CrPhCH}_{2}$ ), fusion fails to occur at all. ${ }^{12}$ This correlation further strengthens the rationale of a mainly steric role for the substituents in the deprotonation process.

Other aspects of the deprotonation reaction, including the consequences of $B$ substitution on the basal ring and the kinetics of the homogeneous reactions with alkyllithium reagents, have
not been addressed in this study but are worthy of investigation and may be examined in future work.

#### Abstract

A fusion temperature versus composition curve has been obtained for the system $\mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$. X -ray single-crystal and powder diffraction methods have been used in combination with Raman spectroscopy to characterize the various phases that are formed. The fusion temperature/composition curve indicates compound formation at $\mathrm{XeF}_{2}$ to $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ ratios (fusion temperature in parentheses): $1: 2\left(89.5^{\circ} \mathrm{C}\right), 2: 1\left(59.5^{\circ} \mathrm{C}\right)$, and $3: 1\left(74.0^{\circ} \mathrm{C}\right)$. Other simple integer combinations are also suggested at the ratios $1: 1\left(56.5^{\circ} \mathrm{C}\right)$ and $3: 2\left(56.0^{\circ} \mathrm{C}\right)$. The high viscosity of the $1: 2$ melt, at its melting point, suggests that the polymeric fluorine-bridged structure of the solid largely persists in the early liquid phase. In contrast the melts of the 1:1 and $2: 1$ are distinctly more mobile and probably consist of the monomeric formula unit species, which are characteristic of the crystalline phases. The deepest eutectic occurs at $49^{\circ} \mathrm{C}$, with $57 \mathrm{~mol} \% \mathrm{XeF}_{2}$. This easily supercools to ambient temperatures. Another well-defined eutectic occurs at $56{ }^{\circ} \mathrm{C}$ with $71.0 \mathrm{~mol} \% \mathrm{XeF}_{2}, \mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5} \mathrm{AsF}_{6}\right)$ is monoclinic, $P 2_{1} / n$, with $a=12.033$ (6) $\AA, b=7.024$ (4) $\AA, c=10.940(5) \AA, \beta=95.43(5)^{\circ}, Z=2$, and $D_{x}=3.61 \mathrm{~g} \mathrm{~cm}^{-3}$. The linear symmetrical XeF $\mathrm{F}_{2}$ species $\left[\mathrm{Xe}-\mathrm{F}=2.0\right.$ (1) $\AA$ ] are coordinated via their F ligands to two equivalent $\mathrm{XeF}_{5}^{+}$ions $[\mathrm{F} \cdots \mathrm{Xe}(\mathrm{VI})=2.76$ (2) $\AA$ and angle $\left.\mathrm{Xe}(\mathrm{II})-\mathrm{F} \cdots \mathrm{Xe}(\mathrm{VI})=139.4(6)^{\circ}\right]$. The $\mathrm{XeF}_{5}{ }^{+}$ions are also bridge bonded to two $\mathrm{AsF}_{6}{ }^{-}$ions $[\mathrm{Xe}(\mathrm{VI}) \cdots \mathrm{F}=2.66$ (1) and 2.74 (1) $\AA]$, the anion thus being coordinated to two cations, a three-dimensional polymer being thereby formed. $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ is monoclinic, $P 2_{1} / n$, with $a=9.159$ (4) $\AA, b=10.158$ (5) $\AA, c=12.401$ ( 6 ) $\AA, \beta=106.66(5)^{\circ}, z=4$, and $D_{x}=3.51 \mathrm{~g}$ $\mathrm{cm}^{-3}$. The structural unit is the formula unit $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \mathrm{AsF}_{6}$. These units are not interconnected. The $\mathrm{XeF}_{2} \mathrm{molecule}^{2}$ is approximately linear $\left[\mathrm{F}-\mathrm{Xe}-\mathrm{F}=178.1(5)^{\circ}\right]$, but the F ligand, which makes a bridge bond to the $\mathrm{XeF}_{5}{ }^{+}$, is elongated $[\mathrm{Xe}-\mathrm{F}$ $=2.06$ (1) $\AA]$ and the other XeF bond is appreciably shortened $[\mathrm{Xe}-\mathrm{F}=1.97$ (1) $\AA]$. The bridge bond to the $\mathrm{XeF}_{5}^{+}$from the $\mathrm{XeF}_{2}$ is short $\left[\mathrm{F}(\mathrm{Xe}) \cdots \mathrm{Xe}(\mathrm{VI})=2.47\right.$ (1) $\AA$ ] as is that from the $\mathrm{AsF}_{6}{ }^{-}$ion $[\mathrm{F}(\mathrm{As}) \cdots \mathrm{Xe}(\mathrm{VII})=2.59$ (1) $\AA$ ]. These two bridging F ligands are coplanar with the $\mathrm{Xe}(\mathrm{VI})$ atom and the axial fluorine of the $\mathrm{XeF}_{5}+$. The symmetry of the cation and its bridging ligands is roughly $C_{2 v} \cdot 2 \mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ is monoclinic, $P 2_{1} / a$, with $a=12.295$ (9) $\AA, b=8.275$ (6) $\AA, c=13.455$ (7) $\AA, \beta=95.67(4)^{\circ}, z=4$, and $D_{x}=3.67 \mathrm{~g} \mathrm{~cm}^{-3}$. As in the $1: 1$ compound, the formula unit is the structural unit and these units are not interconnected. The $\mathrm{XeF}_{2}$ molecules are again nearly linear $\left[\mathrm{F}-\mathrm{Xe}-\mathrm{F}=177\right.$ (1) and 179 (1) ${ }^{\circ}$ ] and the $\mathrm{Xe}-\mathrm{F}$ bond involving F bridging to the cation is in each case elongated $[\mathrm{F} \cdots \mathrm{Xe}(\mathrm{VI})=2.05$ (1) $\AA$ for each] and the nonbridging $\mathrm{Xe}-\mathrm{F}$ is shortened slightly [1.99 (1) and 2.01 (1) $\AA$ ]. These $\mathrm{XeF}_{2}$ interactions with $\mathrm{XeF}_{5}{ }^{+}$are evidently weaker than in the 1:1 compound, the $\mathrm{F}(\mathrm{Xe}) \cdots \mathrm{Xe}(\mathrm{VI})$ bridging distances in this case being 2.53 (1) and 2.54 (1) $\AA$. The bridging F ligands from the two attached $\mathrm{XeF}_{2}$ molecules are coplanar with the axial $\mathrm{Xe}-\mathrm{F}$ unit of the cation. This indicates that the closest F ligand of the $\mathrm{AsF}_{6}{ }^{-}$to the $\mathrm{XeF}_{5}{ }^{+}$, at 2.94 (1) $\AA$, is interacting only weakly with the cation. Differences in the coordination number of the $\mathrm{XeF}_{5}{ }^{+}$cation in these complexes account for the polymeric or nonpolymeric nature of the complexes. Such differences are determined by the extent of ionization of the $\mathrm{XeF}_{2}$ species. The observed, essentially linear, distortions of $\mathrm{XeF}_{2}$ are interpreted as points on the ionization pathway $\mathrm{XeF}_{2} \rightarrow \mathrm{XeF}^{+}+\mathrm{F}^{-}$. From the force constants, and associated interatomic distances, the isolated $\mathrm{XeF}^{+}$ion is predicted to have a bond length of $\sim 1.92 \AA$ and a force constant of $\leqslant 4.48 \mathrm{mdyn} / \AA$.

From theoretical considerations Jortner, Rice, and Wilson in 1963 concluded ${ }^{2}$ that the bond ionicity in xenon difluoride was approximately $\mathrm{F}^{-0.5}-\mathrm{Xe}^{1+}-\mathrm{F}^{-0.5}$ and on this basis they predicted that the enthalpy of sublimation, $\Delta H^{\circ}{ }_{\text {sub }}$, should be $13.3 \mathrm{kcal} \mathrm{mol}^{-1}$.

[^0]This derived largely from the lattice energy contributed by the semi-ionic lattice. Subsequently Schreiner and his co-workers ${ }^{3}$ determined the sublimation enthalpy by experiment and found $\Delta H^{\circ}{ }_{\text {sub }}=13.2 \pm 0.2 \mathrm{kcal} \mathrm{mol}^{-1}$. This gave striking support for the proposed high bond polarity in the molecule. Similar high

[^1]bond ionicities have been indicated from ESCA ${ }^{4}$ and Mössbauer ${ }^{5}$ spectroscopy for other xenon fluorides and oxyfluorides and for the halogen fluorides from ESCA. ${ }^{6}$ The semi-ionic bonding of these molecules provides the lattice energy which stabilizes molecular adducts such as $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{4},{ }^{7} \mathrm{XeF}_{2} \cdot \mathrm{IF}_{5},{ }^{8}$ and $\mathrm{XeF}_{2} \cdot \mathrm{XeOF}_{4} .{ }^{9}$ In these adducts the individual molecular species have essentially the same size and shape as in a crystal of the pure component. In all of them the $F$ ligands of one molecule show maximum avoidance of other $F$ ligands and are directed toward the central atom (positively charged) of the other molecule. This provides the best lattice energy for the semi-ionic assembly.

The isoelectronic relationship and near identity of shape of $\mathrm{XeF}_{5}{ }^{+}$to $\mathrm{IF}_{5}$ and $\mathrm{XeOF}_{4}$ suggested that $\mathrm{XeF}_{2}$ might also make adducts with that ion. It was, however, recognized from the work of Berkowitz and his co-workers ${ }^{10}$ that the enthalpy of ionization, $\Delta H^{\circ}\left(\mathrm{XeF}_{x(\mathrm{~g})} \rightarrow \mathrm{XeF}_{(\mathrm{g}) x-1}+\mathrm{F}_{(\mathrm{g})}^{-}\right.$, of $\mathrm{XeF}_{2}(9.45 \mathrm{eV})$ was only slightly greater than that of $\mathrm{XeF}_{6}(9.24 \mathrm{eV})$. This small difference is offset somewhat by the slightly more favorable lattice enthalpy for a $\mathrm{XeF}^{+}$salt when compared with its $\mathrm{XeF}_{5}^{+}$relative. This is because of the smaller size of the former cation. The possibility therefore existed for the acid-base interactions

$$
\begin{equation*}
\mathrm{XeF}_{2}+\mathrm{XeF}_{5}^{+} \rightarrow \mathrm{XeF}^{+}+\mathrm{XeF}_{6} \tag{1}
\end{equation*}
$$

Adducts of $\mathrm{XeF}_{2}$ with $\mathrm{XeF}_{5}$ salts were indeed found ${ }^{9}$ and Raman spectroscopy (and particularly the intense totally symmetric stretching vibration at $496 \mathrm{~cm}^{-1}$ characteristic ${ }^{11}$ of $\mathrm{XeF}_{2}$ ) indicated that in the adduct $\mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5} \mathrm{AsF}_{6}\right)$ the $\mathrm{XeF}_{2}$ molecule was indistinguishable from that in crystalline $\mathrm{XeF}_{2}$ itself and therefore was effectively of $D_{\infty h}$ symmetry. Raman spectroscopy showed that the symmetric stretching vibration of $\mathrm{XeF}_{2}$ was not present in the $1: 1$ adduct, $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \mathrm{AsF}_{6}$. But two bands, at 557 and $429 \mathrm{~cm}^{-1}$ (average $494 \mathrm{~cm}^{-1}$ ), were identified as XeF stretching modes of what was conjectured to be a linearly distorted $\mathrm{XeF}_{2}$ molecule. This suggested that the $\mathrm{XeF}_{2}$ molecule in this instance was interacting strongly with the $\mathrm{XeF}_{5}^{+}$as though on the reaction pathway for eq 1. Other adducts between $\mathrm{XeF}_{2}$ and $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ appeared to be possible but no others were specifically identified at that time.

The low melting point observed for the $1: 1$ adduct $\left(\sim 57^{\circ} \mathrm{C}\right)$ relative to the separate components $\left(\mathrm{XeF}_{2}, 129^{\circ} \mathrm{C} ; \mathrm{XeF}_{5} \mathrm{AsF}_{6}\right.$, $132{ }^{\circ} \mathrm{C}$ ) and the hint of even lower melting materials, taken together with the observation that the Raman spectra at the melting points are similar to those of the crystalline solids, suggested that these and other $\mathrm{XeF}_{2} \cdot n\left(\mathrm{XeF}_{5} \mathrm{MF}_{6}\right)$ salts could provide low-temperature melts, which would be highly resistent to further oxidation. These are of particular interest as potential sources of $\mathrm{MF}_{6}$ via anodic oxidation of the $\mathrm{MF}_{6}{ }^{-}$salts.

In order to obtain a firmer understanding of the factors that determine adduct formation and also to investigate the possibility of lower fusion temperatures, the phase diagram for the $\mathrm{XeF}_{2}$ / $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ system has been broadly surveyed. Representative structures (for the $\mathrm{XeF}_{2}: \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ ratios 1:2, 1:1, and 2:1) have been carried out with X-ray single-crystal diffraction methods. Structural changes and relationships have been otherwise followed by X-ray powder photography and Raman spectroscopy. This paper describes the main findings.

## Experimental Section

Melting Point Measurements in the System $\mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$. Materials. $\mathrm{XeF}_{2}$ and $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ were prepared as previously described. ${ }^{12,13}$

Figure 1. Fusion temperature composition curve for $\mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$.
All handling of the solids was carried out in the dry-nitrogen atmosphere of a Vacuum Atmospheres Corp. Drilab or in another drybox of comparable dryness.

Apparatus. A thin-walled quartz ampule of $\sim 10 \mathrm{~cm}^{3}$ capacity joined to a nickel needle valve via Teflon-gasketed compression fittings was used to contain the samples to be melted. A Teflon-coated stirrer bar was placed in the ampule with the sample.

Sample Preparation. Each compound ( $\mathrm{XeF}_{2}$ and $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ ) was separately weighed into the quartz ampule in the drybox. Each quantity was roughly determined with a balance housed in the drybox and subsequently measured with a balance outside the box with a precision of $\pm 0.1 \mathrm{mg}$. The total quantity of adduct prepared was in each case 12 to 15 mmol . After the more precise weighing (which provided the composition) the entire capsule volume was immersed in hot water, to a point beyond the valve seat, so that the sample melted completely. The melt was then homogenized by stirring and subsequently cooled to solidify the sample. A melting point determination was carried out on that solidified sample. By removing $\mathrm{XeF}_{2}$ under vacuum (the loss being assessed gravimetrically) the composition of the material in the ampule was progressively enriched in $\mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}$. After each such adjustment in composition the residual material was homogenized by stirring of the melt. A melting point was carried out on this solidified, homogenized material. Only 4 to 5 adjustments in composition of this kind were made, then a fresh mixture of $\mathrm{XeF}_{2}$ and $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ was prepared so as to provide a compositional overlap with the previous one.

Measurements. A thermostat bath containing water or glycerine (at temperatures above $95^{\circ} \mathrm{C}$ ) was used in the melting point determinations. The temperature was regulated to $\pm 0.02{ }^{\circ} \mathrm{C}$. A calibrated thermometer was used. The melting point was taken as the temperature at which the last crystals of solid became liquid or at which turbidity cleared.

Raman spectra were typically obtained from samples sealed in thinwalled quartz capillaries of $\sim 1 \mathrm{~mm}$ diameter. Spectra were recorded with a Spex 1401 double monochromator with either krypton or argon ion laser radiation.

X-ray Structure Determinations. Crystals of the three compositions reported in this paper were grown in $0.3-\mathrm{mm}$ evacuated quartz capillaries. The details of the crystal shape, color, and size are recorded in Table I. The crystals were mounted on a Picker FACS-I automated diffractometer equipped with a scintillation counter, a graphite monochromator, and a Mo X-ray tube. The setting angles of 12 manually centered reflections $\left[37^{\circ}<2 \theta<51^{\circ}\right.$ for $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}$ and $37^{\circ}<2 \theta<41^{\circ}$ for $\mathrm{XeF}_{2} \cdot 2-$ $\left.\left(\mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}\right)\right]$ were used to determine the cell dimensions by a leastsquares procedure; the setting angles of 3 reflections ( $0,8,0 ; 12,0,0$; and $0,0,13$ ) were used to determine the cell dimensions of $2 \mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}$; the results are shown in Table I. The intensity data were collected by using the $\theta-2 \theta$ scan, and most of the details of the data acquisition and results are shown in Table I. Crystal decay factors based on the variations of the standards reflections, absorption corrections, ${ }^{14}$ and Lor-entz-polarization corrections were applied to the intensity data. A perusal of the strong reflections after several least-squares refinements indicated an extinction correction would be warranted for the $\mathrm{XeF}_{2}$. $2\left(\mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}\right)$ data only, and such a correction was made (see Table I).

Three-dimensional Patterson functions showed the positions of the Xe and As atoms. Subsequent least-squares refinements, Fourier calculations, and difference Fourier calculations revealed the fluorine atom positions. Least-squares refinements, in which the function $\sum w\left(\left|F_{\mathrm{o}}\right|-\right.$ $\left.\left|F_{\mathrm{c}}\right|\right)^{2} / \sum w F_{0}{ }^{2}$ was minimized, converged rapidly to the final structures. Scattering factors of Doyle and Turner ${ }^{15}$ were used, and anomalous dispersion corrections ${ }^{16}$ were applied. The resulting $R$ factors are given in Table I.

## Results and Discussion

The fusion temperature versus composition curve for the system $\mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ is given in Figure 1. Points of inflection for the $\mathrm{XeF}_{2}: \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ combining ratios $1: 2$ and $1: 1$ and a maximum at $2: 1$ indicate adduct formation at these compositions. Crystals of these compounds were obtained and their structures have been determined from X-ray diffraction data. The change in slope of the fusion temperature composition curve in the neighborhood of the composition 3:1 also indicated compound formation, but attempts to secure crystals of that composition were not successful.

The fusion temperature of the $\mathrm{XeF}_{2} \cdot 2 \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ compound is close to $90^{\circ} \mathrm{C}$. Addition of $\mathrm{XeF}_{2}$ brings about a steep drop in fusion temperature with composition. From approximately 38.5 to $45 \mathrm{~mol} \% \mathrm{XeF}_{2}$, in the binary mixture with $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$, the fusion temperature remains approximately constant at $\sim 61^{\circ} \mathrm{C}$. This composition range spans the $\mathrm{XeF}_{2}: \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ stoichiometries 2:3 ( $40 \%$ ), $3: 4$ ( $42.9 \%$ ), and $4: 5$ ( $44.4 \%$ ) but no convincing crystallographic nor Raman spectroscopic evidence was obtained for any of these possible phases.

The Raman spectra of the three structurally defined phases, with assignments, are given in Figure 2 where they are compared with the spectrum of $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$. These spectra are essentially

[^3]the same as those of the earlier study ${ }^{9}$ with the spectrum of the $2: 1$ compound $\left(\mathrm{XeF}_{2}\right)_{2} \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ added. The $\mathrm{Xe}-\mathrm{F}$ stretching features of that compound, at $420,438,479,542$, and $550 \mathrm{~cm}^{-1}$, immediately indicate that the $\mathrm{XeF}_{2}$ ligands in the $2: 1$ compound, like that of the $1: 1$ compound, must be distorted from the $D_{\infty h}$ (idealized) geometry. For $\mathrm{XeF}_{2}$ in the 1:2 compound, or in $\mathrm{XeF}_{2}$ (crystalline) itself, ${ }^{11}$ the $\mathrm{Xe}-\mathrm{F}$ stretching is represented by a single intense band at or near $496 \mathrm{~cm}^{-1}$.

The Raman spectra of solids at the compositions 2:3; 3:4, 4:5, and 5:6 did not give clear indication of discrete phases having these compositions. All spectra in that range had the appearance of mixtures of the $1: 2$ and $1: 1$ compounds.
Because of the change in slope of the fusion temperature composition curve at the $3: 1$ composition a more thorough search for compound formation was made at that composition. Raman spectra, shown in Figure 3, were obtained (A) for the melt at 80 ${ }^{\circ} \mathrm{C}$, (B) for the solid, immediately after solidification of the melt, and (C) for the solid at $\sim 20^{\circ} \mathrm{C}$. From a comparison of the last with the spectrum of $\left(\mathrm{XeF}_{2}\right)_{2} \mathrm{XeF}_{5} \mathrm{AsF}_{6}$, given in Figure 2, it is evident that the $3: 1$ material is merely a mixture of the $2: 1$ compound and $\mathrm{XeF}_{2}$ (the latter giving rise to the $496-\mathrm{cm}^{-1}$ band). The Raman spectrum of the $3: 1$ composition solid immediately after solidification of the melt (spectrum B) does, however, differ from that at $20^{\circ} \mathrm{C}$ and could signify a structural rearrangement toward a material in which the $\mathrm{XeF}_{5}{ }^{+}$is coordinated by three $\mathrm{XeF}_{2}$ molecules rather than the two $\mathrm{XeF}_{2}$ and one $\mathrm{AsF}_{6}{ }^{-}$of the $20^{\circ} \mathrm{C}$ solid. The shift of the XeF stretch in the higher temperature solid at $496 \mathrm{~cm}^{-1}$ (which signifies undistorted $\mathrm{XeF}_{2}$ ) to 506 and $\sim 462$ $\mathrm{cm}^{-1}$ (spectrum A ) in the melt could mean that all of the $\mathrm{XeF}_{2}$ is unsymmetrically attached to $\mathrm{XeF}_{5}{ }^{+}$at or near the fusion temperature.
The chemically significant atomic arrangements from the $1: 2$; 1:1, and $2: 1$ structural analyses are illustrated in Figures 4, 5, and

Figure 2. Raman spectra of the $2: 1,1: 1$, and $1: 2 \mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ compounds and $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$.
6. Positional parameters for all three structures are given in Table II, and lists of distances and angles are given in Tables III and IV. Thermal parameters are available in the supplementary material.
The coordination of the $\mathrm{XeF}_{5}{ }^{+}$cation by fluorine ligands is variable. The three structures in the present study illustrate this, but similar observations have been made previously. ${ }^{17}$ All known coordination geometries for this cation fit the conception of it as a square-pyramidal species (essentially of $C_{4 v}$ symmetry) with

[^4]

Figure 3. Raman spectra of 3:1 $\mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ (A, melt at $\sim 80^{\circ} \mathrm{C}$; B , solid at $\sim 70^{\circ} \mathrm{C}$; C, solid at $\sim 20^{\circ} \mathrm{C}$ ).
positive charge centered effectively at the xenon atom. This charge is shielded not only by the five fluorine ligands but also by the formally nonbonding xenon valence electron pair. This electron

${ }^{a}$ Here and in the following tables the number in parentheses is the estimated standard deviation for the least significant figures.
pair is visualized as occupying the sixth coordination site of the pseudooctahedral cation. In harmony with this picture, fluorine ligands of molecules or ions which make close approach to $\mathrm{XeF}_{5}{ }^{+}$ do so at an angle of $\sim 50^{\circ} \mathrm{C}$ to the fourfold axis on which the electron pair is deemed to be concentrated. These ligands, two or three, as here, but in other structures four in number, are generally distributed to maximize their mutual separation. All of this fits the notion of a discrete cation, attracting ligands of other species electrostatically.

The $\mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}\right)$ structure is shown in Figure 4. The xenon difluoride molecule, which is centered on a center of symmetry, has an Xe-F interatomic distance of 2.01 (1) $\AA$ (2.03 (1) $\AA$ corrected for thermal motion) and is therefore not significantly different from $\mathrm{XeF}_{2}$ in the crystalline solid ${ }^{7}$ where the $\mathrm{Xe}-\mathrm{F}$ distance is 2.01 (1) $\AA$. This is in harmony with the identity of the symmetric vibration for the $\mathrm{XeF}_{2}$ in $\mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5} \mathrm{AsF}_{6}\right)$ at $496 \mathrm{~cm}^{-1}$ (see figure 2) with that ${ }^{11}$ of crystalline $\mathrm{XeF}_{2}$ at $496 \mathrm{~cm}^{-1}$.

Figure 4. ORTEP drawing of the molecular unit of $\mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5}^{+} \cdot \mathrm{AsF}_{6}{ }^{-}\right)$ with use of $50 \%$ probability ellipsoids. Two extra $F(8)$ atoms have been included to show the complete bonding environment of $\mathrm{Xe}(2)$.

Figure 5. ORTEP drawing of one molecular unit of $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5}^{+} \cdot \mathrm{AsF}_{6}^{-}$ with use of $50 \%$ probability ellipsoids.

The $\mathrm{XeF}_{5}$ and $\mathrm{AsF}_{6}{ }^{-}$species are very similar to their relatives in ${ }^{13}$ the parent material, $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$. The cation is linked to one $\mathrm{XeF}_{2}$ and two $\mathrm{AsF}_{6}{ }^{-}$via F bridges: the $\mathrm{XeF}_{2}$ at 2.76 (1) $\AA$ and the two separate $\mathrm{AsF}_{6}{ }^{-}$at 2.66 (1) and 2.74 (1) $\AA$. The coordination of $\mathrm{XeF}_{5}{ }^{+}$in $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ is similar. There, two of the bridging F ligands (at 2.73 (2) and 2.83 (2) $\AA$ ) are cis related fluorine atoms of one $\mathrm{AsF}_{6}{ }^{-}$, and the other (at 2.65 (2) $\AA$ ) is contributed by a second $\mathrm{AsF}_{6}$. By this arrangement two formula units in $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ are related by a center of symmetry and form a molecular unit which is also the structural unit. When $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ is melted, the liquid is mobile. This is in sharp contrast to the viscous melt given by $\mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5} \mathrm{AsF}_{6}\right)$. The $\mathrm{XeF}_{2}$ molecule, by its bridging interaction with the two $\mathrm{XeF}_{5}{ }^{+}$, contributes to the polymeric nature of the $\mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5} \mathrm{AsF}_{6}\right)$ material. This polymeric nature also derives from the bridge bonds that each cation makes to two separate $\mathrm{AsF}_{6}{ }^{-}$. Each $\mathrm{AsF}_{6}{ }^{-}$in turn is linked to two $\mathrm{XeF}_{5}{ }^{+}$to generate an extended three-dimensional network. Evidently the interaction between the various species in the crystal must be largely retained in the melt close to the melting point, since the Raman spectra of solid and melt are similar.
When the $1: 2$ phase is enriched with $\mathrm{XeF}_{2}$ the only new phase observed, up to the composition 1:1, is the phase with the latter composition. This has the structure illustrated in Figure 5. Both the $\mathrm{XeF}_{2}$ and the $\mathrm{XeF}_{5}{ }^{+}$are differently coordinated from their situations in $\mathrm{XeF}_{2} \cdot 2 \mathrm{XeF}_{5} \mathrm{AsF}_{6}$. a one-on-one interaction of $\mathrm{XeF}_{2}$ with $\mathrm{XeF}_{5}{ }^{+}$is preferred in the $1: 1$ compound. This evidently is

${ }^{a}$ Estimated standard deviations for all angles are $\pm 1^{\circ}$. ${ }^{b}$ Angle is $180^{\circ}$ by symmetry.
associated with both the distortion of the linear $\mathrm{XeF}_{2}$ and the lowering of the coordination number of the $\mathrm{XeF}_{5}{ }^{+}$, from three bridging $F$ ligands in the $1: 2$ compound ( 2.66 (2), 2.74 (2), and 2.76 (2) $\AA$ ) to two in the $1: 1$ compound ( 2.47 (2) and 2.59 (2) Å).

These structural changes must be a consequence of the easy transition of the semi-ionic symmetrical $\mathrm{F}-\mathrm{Xe}-\mathrm{F}$ toward the ion pair ( $\mathrm{F}-\mathrm{Xe})^{+} \mathrm{F}^{-}$. In the symmetrical electrostatic field provided by the structural arrangement in the 1:2 compound, the $\mathrm{XeF}_{2}$ is indistinguishable from $\mathrm{XeF}_{2}$ in the crystalline solid. But in the unsymmetrical field of the single $\mathrm{XeF}_{5}{ }^{+}$of the $1: 1$ compound the progression toward ionization is easily perceived, both in the
observed interatomic distances and in the vibrational spectra. The diminished coordination number of the $\mathrm{XeF}_{5}{ }^{+}$in the $1: 1$ compound must be a consequence of the high charge on the bridging $F$ ligand of the $\mathrm{XeF}_{2}$. That high charge brings it closer to the $\mathrm{XeF}_{5}{ }^{+}$and screens that cation charge more effectively while simultaneously repelling other negatively charged ligands. Thus the coordination of the $\mathrm{XeF}_{5}{ }^{+}$by only two F ligands is easily understood. As a consequence of these strong linkages of the $\mathrm{XeF}_{5}{ }^{+}$to the $\mathrm{XeF}_{2}$ and the $\mathrm{AsF}_{6}{ }^{-}$, the formula unit represents a discrete structural unit. This "molecular" structure accounts for the higher mobility of the melt, which contrasts with the viscous one obtained on melting the $1: 2$ compound.

Figure 6. ORTEP drawing of the molecular unit of $2 \mathrm{XeF}_{2} \cdot\left(\mathrm{XeF}_{5}{ }^{+} \cdot \mathrm{AsF}_{6}{ }^{-}\right)$ with use of $50 \%$ probability ellipsoids.

It is of interest that the $1: 1$ structure has the form shown, rather than the polymeric form $\cdot . \mathrm{FXeF} \cdot \mathrm{XeF}_{5}^{+} . . \mathrm{FXeF} .$. with symmetrical $\mathrm{XeF}_{2}$ and three coordinated $\mathrm{XeF}_{5}{ }^{+}$, as in the 1:2 compound (the $\mathrm{AsF}_{6}{ }^{-}$would complete the $\mathrm{XeF}_{5}{ }^{+}$coordination). Presumably the bonding energy for the polymeric form, if better than for the monomer, is insufficiently superior to offset the disadvantageous entropy of the polymer, relative to the monomer. It must be supposed that the polymeric $1: 2$ structure occurs because the binding of symmetrical $\mathrm{XeF}_{2}$ to $\mathrm{XeF}_{5}{ }^{+}$is energetically better than the binding of a second F ligand of $\mathrm{AsF}_{6}{ }^{-}$(the $\mathrm{XeF}_{5}{ }^{+}$is coordinated by one F ligand of one anion and two of a second in $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ ). Clearly, however, the 1:1 "molecular" structure with its partially ionized $\mathrm{XeF}_{2}$ does not persist in the presence of $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$. Evidently in that situation the $\mathrm{XeF}_{5}{ }^{+}$captures the remaining F ligand of the partially ionized $\mathrm{XeF}_{2}$ of the $1: 1$ compound and produces the symmetrically bridged 1:2 polymer.

The structure of the $2: 1$ compound, shown in Figure 6, is entirely consistent with the coordination character seen in the other structures. Here, as in the $1: 1$ compound, the $\mathrm{XeF}_{2}$ is coordinated singly by the $\mathrm{XeF}_{5}{ }^{+}$species. As is appropriate for the $2: 1$ stoichiometry, each $\mathrm{XeF}_{5}{ }^{+}$has two $\mathrm{XeF}_{2}$ molecules coordinated via short $\mathrm{Xe} \cdots \mathrm{F}$ bridges of 2.53 (1) and 2.54 (1) $\AA$. The $\mathrm{XeF}_{5}{ }^{+}$ coordination is indeed similar to that of the $1: 1$ compound with the coordinated $\mathrm{AsF}_{6}{ }^{-}$of that arrangement having been replaced by the second $\mathrm{XeF}_{2}$ molecule. The bridging F ligands of the two $\mathrm{XeF}_{2}$ molecules, the $\mathrm{Xe}(\mathrm{VI})$ atom and its axial F ligand (F5), lie in the same plane (the sum of angles $F(6)-X e(3)-F(8), F(6)-$ $\mathrm{Xe}(3)-F(5)$, and $F(8)-\mathrm{Xe}(3)-F(5)$ is $\left.359.4(17)^{\circ}\right)$. It therefore appears that the $\mathrm{Xe}(\mathrm{VI})^{+} \ldots \mathrm{FAsF}_{5}^{-}$interatomic distance of 2.94 (1) Å represents merely a secondary close-packing interaction, that fluorine ligand not being part of the primary coordination sphere of the cation. Although the two $\mathrm{XeF}_{2}$ molecules coordinated to the $\mathrm{XeF}_{5}{ }^{+}$in the 2:1 compound are not crystallographically equivalent they are not significantly different in their interatomic distances and orientation with respect to the cation. The $\mathrm{XeF}_{2}$ molecules do not interact as strongly with the $\mathrm{XeF}_{5}{ }^{+}$in this 2:1 complex as does the $\mathrm{XeF}_{2}$ in the $1: 1$ compound. This is expressed not only in the shorter $\mathrm{Xe}(\mathrm{VI}) \cdots \mathrm{F}$ distance in the $1: 1$ versus the $2: 1$ compound ( 2.47 (1) versus 2.53 (1) $\AA$ ) but in the greater distortion in the former relative to the latter (2.06 (1) with 1.97 (1) $\AA$ versus 2.05 (1) with 1.99 (1) or 2.01 (1) $\AA$ ). This may simply be a consequence of the mutual repulsion of the two $\mathrm{XeF}_{2}$ ligands of the cation in the $2: 1$ compound being greater than the repulsive interaction of the single $\mathrm{XeF}_{2}$ and the coordinated $\mathrm{AsF}_{6}$ ion. Indeed the two $\mathrm{XeF}_{2}$ molecules coordinated to the cation in the $2: 1$ compound are so coordinated (as can be seen from figure 6) that the two xenon atoms (each positively charged) are well

${ }^{a}$ Interatomic distances given within square brackets are distances corrected for the riding motion of the $F$ atom on the Xe atom. ${ }^{b}$ The force constants were evaluated following Herzberg ${ }^{28}$ with $\lambda_{1}+\lambda_{3}=$ $\mu_{\mathrm{F}}\left(k_{1}+k_{2}\right)+\mu_{\mathrm{Xe}}\left(k_{1}+k_{2}-2 k_{12}\right)$ and $\lambda_{1} \lambda_{3}=\left(k_{1} k_{2}-k_{12}^{2}\right)\left(\mu_{\mathrm{F}}^{2}+\right.$ $\left.2 \mu_{\mathrm{F}} \mu_{\mathrm{Xe}}\right) ; \lambda_{2}=4 \pi^{2} c^{2} \nu_{\mathrm{i}}^{2}$ and $\mu_{\mathrm{i}}$ reciprocal atomic masses. The $k_{12}$ for $\mathrm{XeF}_{2}$ was used for the other cases. ${ }^{c}$ Reference 20. ${ }^{d}$ Reference 26. ${ }^{e}$ Reference 21. ${ }^{f}$ Reference 27. ${ }^{8}$ Reference $18 .{ }^{h}$ Reference 13. ${ }^{\text {i Reference 23. }}$ 'Reference 11.
separated from one another. Clearly the formula unit $2 \mathrm{XeF}_{2}$. $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ forms a discrete unit. Like the melt of the $1: 1 \mathrm{com}-$ pounds, that of the $2: 1$ compounds is much more mobile than that given by the $1: 2$ material; moreover the eutectic between the "molecular" $1: 1$ and $2: 1$ materials provides the lowest fusion temperature in this system. This, and compositionally close melts, readily supercool to room temperatures.

The $\mathrm{XeF}_{2}$ molecules seen in the present structures conform to the now well documented pattern of Xe (II) linearly coordinated by only two F ligands. The distortions from centrosymmetry, seen in the $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ and the $\left(\mathrm{XeF}_{2}\right)_{2} \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ structure, are less extreme versions of the distortions previously described for $\mathrm{XeF}_{2}$ coordinated to strong fluoride ion acceptors. Table V gives the essential dimensions and vibrational data that characterize these linearly distorted $\mathrm{F}-\mathrm{Xe} \ldots \mathrm{F}$ systems. Undistorted $\mathrm{XeF}_{2}$ data are included for comparison purposes. All observations are compatible with linearly coordinated $\mathrm{Xe}(\mathrm{II})$ with one F ligand departing on the $\mathrm{F}-\mathrm{Xe}-\mathrm{F} \rightarrow \mathrm{F}-\mathrm{Xe}^{+} \ldots \mathrm{F}^{-}$ionization pathway toward the $\mathrm{XeF}_{5}{ }^{+}$cation. The situation is related to that observed in the $1: 1$ complexes (roughly formulated as $\mathrm{XeF}^{+} \mathrm{MF}_{6}{ }^{-}$) which $\mathrm{XeF}_{2}$ makes with strong fluoride ion acceptors ${ }^{18-20}$ (e.g., $\mathrm{M}=\mathrm{As}$, $\mathrm{Ru}, \mathrm{Sb}$ ) and that which occurs ${ }^{13}$ in the complex cation $\mathrm{Xe}_{2} \mathrm{~F}_{3}{ }^{+}$. These geometries are compared in Table V. In all cases the lengthening of one $\mathrm{Xe}-\mathrm{F}$ bond is accompanied by the contraction of the other. Evidently the canonical form $\left\{(\mathrm{F}-\mathrm{Xe})^{+} \mathrm{F}^{-}\left(\mathrm{XeF}_{5}\right)^{+}\right\}$ is more important than $\left\{\mathrm{F}^{-}(\mathrm{Xe}-\mathrm{F})^{+}\left(\mathrm{XeF}_{5}\right)^{+}\right\}$. The weakening of one bond of the $\mathrm{XeF}_{2}$ and the strengthening of the other is indicated by the vibrational data. Vibrational aspects of $\mathrm{XeF}_{2}$ complexes with fluoride ion acceptors have been discussed previously. ${ }^{21.22}$
From the data on FXeF species in Table V the most distorted (and ionized) form is seen to be that in the compound ${ }^{20} \mathrm{FXeF}$ $\mathrm{Sb}_{2} \mathrm{~F}_{10}$. Although the interatomic distances in the crystal are imprecise [ $\mathrm{Xe}-\mathrm{F}=1.82$ (3) and 2.34 (3) $\AA$ ], the vibrational data clearly indicate the greatest force constant differences for any

[^5]

Figure 7. Force constant-interatomic distance relationships for $\mathrm{XeF}_{2}$ species ( $\theta$, distances corrected for the riding of F on Xe ; 一 $\mid$, uncorrected distances): (1) $\mathrm{FXeFSb}_{2} \mathrm{~F}_{10}$, (2) $\mathrm{FXeFAsF}_{5}$, (3) $\mathrm{Xe}_{2} \mathrm{~F}_{3} \mathrm{AsF}_{6}$, (4) $\mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \mathrm{AsF}_{6}$, and (5) $\mathrm{XeF}_{2} \cdot 2 \mathrm{XeF}_{5} \mathrm{AsF}_{6}$.
linearly distorted FXeF species, that for the shorter bond being 3.76 and the larger 0.72 mdyn $/ \AA$. These values together with the force constant for the bonds in the symmetrical $\mathrm{XeF}_{2}$, which is $2.68 \mathrm{mdyn} / \AA$, provide a basis for assessing the charge distribution in the $\mathrm{XeF}_{2} / \mathrm{XeF}_{5}+$ complexes.

Since the $\mathrm{XeF}_{2}$ in the $\mathrm{XeF}_{2} \cdot 2\left(\mathrm{XeF}_{5} \mathrm{AsF}_{6}\right)$ compound is indistinguishable dimensionally and vibrationally from crystalline $\mathrm{XeF}_{2},{ }^{23}$ the F ligand charge must be the same. The Jortner et al. ${ }^{2}$ value of -0.5 e is therefore appropriate. The charge on the longer bonded $F$ ligand in the $1: 1$ and $2: 1$ compounds must exceed this. Yet the degree of ionization in these FXeF species is clearly much less than that in the $\mathrm{FXeFSb} \mathrm{F}_{2} \mathrm{~F}_{10}$ situation.

From the force constant dependence upon interatomic distance for the linearly distorted FXeF species illustrated in Figure 7, it is seen that the force constant rises sharply as the short bond interatomic distance approaches a limiting value. The sum of the force constants decreases as the distortion increases (see Table V). If this trend continues, as seems likely, to the ionization limit, the force constant for the fully ionized $(\mathrm{Xe}-\mathrm{F})^{+}$species must be
(23) Levy, H. A.: Agron, P. A. In Noble Gas Compounds; Hyman, H. H., Ed.; The University of Chicago Press: Chicago and London, 1963; p 221 .
$\leqslant 4.48$ (i.e., $3.76+0.72$ ) mdyn $/ \AA$. This suggests an interatomic distance for the cation $(\mathrm{Xe}-\mathrm{F})^{+}$, based on the corrected data of $\sim 1.92 \AA$. The uncorrected data indicate a somewhat lower cation interatomic distance of $\sim 1.86 \AA$. Spectroscopic data for the isoelectronic I-F species provide an interatomic distance ${ }^{24}$ of $1.908_{9}$ $\AA$. It appears that the $(\mathrm{Xe}-\mathrm{F})^{+}$distance must be very similar. Clearly the $\mathrm{XeF}_{2}$ molecules, which are coordinated to only one $\mathrm{XeF}_{5}{ }^{+}$, are in the early stages of ionization. In each case the charge on the long-bonded $F$ ligand must be $>0.5 e$ (the charge of the undistorted $\mathrm{XeF}_{2}$ ligand) but $\ll 1.0 \mathrm{e}$.

In studies related to those of this paper Žemva and his coworkers ${ }^{25}$ have shown that the salt $\mathrm{XeF}_{5} \mathrm{RuF}_{6}$ forms a 1:1 complex with $\mathrm{XeF}_{2}$ whereas the isostructural relative $\mathrm{XeF}_{5} \mathrm{NbF}_{6}$ does not. They have also been unable to form $\mathrm{XeF}_{2} / \mathrm{XeF}_{5}{ }^{+}$complexes of salts of dianions. These observations fit the model developed in the rationalization of the $\mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ structures. Clearly the $\mathrm{XeF}_{2}$ must be capable of displacing F bridges of the anion to the $\mathrm{XeF}_{5}{ }^{+}$in the parent $\mathrm{XeF}_{5}\left(\mathrm{MF}_{6}\right)$ structure, if a $\mathrm{XeF}_{2}$ complex is to exist. In general, the higher the negative charge on each ligand of the anion, the less effective will be the $\mathrm{XeF}_{2}$ in displacing such a ligand from a bridging interaction with $\mathrm{XeF}_{5}{ }^{+}$. Since the ligand charge on $\mathrm{MF}_{6}^{-}$must decrease across each transition series (when the formally nonbonding electrons are in $t_{2 g}$ orbitals) the ligands of $\mathrm{XeF}_{2}$ are more likely to displace $\mathrm{MF}_{6}{ }^{-}$bridges to $\mathrm{XeF}_{5}{ }^{+}$when M is at or near the end of a transition series. For similar reasons it is unlikely that $\mathrm{XeF}_{2} / \mathrm{XeF}_{5}{ }^{+}$complexes can occur with doubly or triply charged anions.

Acknowledgment. The authors gratefully acknowledge the following support: Preparations and crystallographic studies of the $2: 1,1: 1$, and $1: 2 \mathrm{XeF}_{2} / \mathrm{XeF}_{5} \mathrm{AsF}_{6}$ complexes were carried out at Berkeley with the support of the Director, Office of Energy Research, Office of Basic Energy Sciences, Chemical Science Division of the U.S. Department of Energy under Contract No. DE-AC03-67SF00098. One of us (B.Z̆.) held a fellowship of the Boris Kidrič Foundation and received travel support from the Senior Fulbright-Hays Program. The full survey of the $\mathrm{XeF}_{2}$ / $\mathrm{XeF}_{5} \mathrm{AsF}_{6}$ system was carried out with the support of the U . S.-Yugoslav Joint Fund for Scientific and Technological Cooperation, in cooperation with the National Science Foundation under Grant No. 552. That part of the work was also supported by the Research Community of Slovenia.

Supplementary Material Available: Tables of thermal parameters for $2 \mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}, \mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}$, and $\mathrm{XeF}_{2} \cdot 2(\mathrm{Xe}-$ $\mathrm{F}_{5} \cdot \mathrm{AsF}_{6}$ ) (2 pages); listing of observed and calculated structure factors for $2\left(\mathrm{XeF}_{2}\right) \cdot \mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}, \mathrm{XeF}_{2} \cdot \mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}$, and $\mathrm{XeF}_{2}$. $2\left(\mathrm{XeF}_{5} \cdot \mathrm{AsF}_{6}\right.$ ) ( 22 pages).
