Bridging ligands are commonly used to prevent fragmentation of binuclear or cluster complexes and have aided the systematic development of chemistry and catalysis involving such compounds. The most commonly used binucleating ligand is bis(diphenylphosphino) methane, dppm, which is relatively inert under mild conditions. ${ }^{2,3}$ However, under basic conditions, the deprotonated form $\left(\mathrm{Ph}_{2} \mathrm{P}\right)_{2} \mathrm{CH}^{-}$may be formed and further derivatized by reaction with electrophiles, while ortho-metalation of a phenyl substituent or cleavage of $\mathrm{Ph}-\mathrm{P}$ or $\mathrm{P}-\mathrm{CH}_{2}$ bonds or both may occur on thermolysis of metal complexes of dppm. ${ }^{4}$ This article reports a new reaction, which occurs at room temperature, to give a formal insertion of acetylide into a CH bond of dppm. The reaction was discovered in an attempt to extend the modeling, using coordinatively unsaturated cluster complexes, of reactions of acetylene on a platinum(111) surface to the binding of a possible acetylide species on platinum. ${ }^{5}$

The new chemistry is summarized in Scheme I. Reaction of $\left[\mathrm{Pt}_{3}\left(\mu_{3}-\mathrm{CO}\right)(\mu-\mathrm{dppm})_{3}\right]^{2+}, \quad 1,{ }^{6} \quad\left[\mathrm{Pt}_{3}\left(\mu_{3}-\eta^{2}-\mathrm{HCCH}\right)(\mathrm{CO})(\mu-\right.$ $\left.\mathrm{dppm})_{3}\right]^{2+}, 2,{ }^{5}$ or $\left[\mathrm{Pt}_{3}\left(\mu_{3}-\eta^{2}-\mathrm{HCCH}\right) \mathrm{Cl}(\mu-\mathrm{dppm})_{3}\right]^{+}, 3,{ }^{5}$ with excess NaCCH in $\mathrm{CH}_{2} \mathrm{Cl}_{2}-\mathrm{xyl}$ lene gave the new complex [ $\mathrm{Pt}_{3}\left(\mu_{3}-\eta^{2}-\right.$ $\left.\mathrm{HCCH})(\mu-\mathrm{dppm})_{2}\left\{\mu_{2}-\eta^{3}-\left(\mathrm{Ph}_{2} \mathrm{P}\right)_{2} \mathrm{CHCH}=\mathrm{CH}\right\}\right]^{+}, 4$, as the $\mathrm{PF}_{6}^{-}$ salt. The reaction with 1 requires proton abstraction from solvent to give the $\mu_{3}-\mathrm{HCCH}$ group and proceeds in lower yield ( $46 \%$ ) compared to the reaction with 3 (yield $82 \%$ ) which does not require this step.

The structure of the cation 4 was determined crystallographically ${ }^{7}$ and is shown in Figure 1. The overall structure is similar to that found for 3 , with some differences in the binding of the HCCH ligand. Thus the $\mathrm{Pt}(3)-\mathrm{C}(5)$ distance $[2.11$ (2) $\AA$ ] is somewhat longer than the analogous distance in $\mathbf{3}$ [1.99 (3) $\AA$ ], reflecting the higher trans influence of the vinylic carbon than of the chloride ligand. The most surprising feature was the formation of the $\mu_{2}-\eta^{3}-3,3$-bis(diphenylphosphino) propen-1-yl ligand, defined in Figure 1 by atoms P(3), P(4), C(2), C(7), and $\mathrm{C}(6)$. The distances $\mathrm{C}(6)-\mathrm{C}(7)$ and $\mathrm{C}(2)-\mathrm{C}(7)$ are 1.30 (3) and 1.57 (3) $\AA$, typical of carbon-carbon double and single bonds,

[^0]

Figure 1. The structure of 4 , with phenyl rings omitted for clarity; the atoms are represented by thermal ellipsoids of $50 \%$ probability. Selected bond lengths are as follows: $\mathrm{Pt}(1)-\mathrm{Pt}(2) 2.655$ (2), $\mathrm{Pt}(1)-\mathrm{C}(4) 2.20$ (2), $\mathrm{Pt}(1)-\mathrm{C}(5) 2.24$ (2), $\mathrm{Pt}(2)-\mathrm{C}(4) 2.04$ (2), $\mathrm{Pt}(3)-\mathrm{C}(5) 2.11$ (2), and $\mathrm{Pt}(3)-\mathrm{C}(6) 2.11$ (2) $\AA$.

Scheme I

respectively. The new ligand bridges the nonbonded metal atoms $\mathrm{Pt}(2)$ and $\mathrm{Pt}(3)$ through the phosphorus donors $\mathrm{P}(3)$ and $\mathrm{P}(4)$, and it also chelates the $\mathrm{Pt}(3)$ center by forming the $\mathrm{Pt}(3)-\mathrm{P}(4)$ and $\mathrm{Pt}(3)-\mathrm{C}(6)$ bonds. There is a severe tetrahedral distortion from square-planar coordination geometry around the $\mathrm{Pt}(3)$ atom $\left[\mathrm{C}(5)-\mathrm{Pt}(3)-\mathrm{C}(6)=158.2(7)^{\circ}, \mathrm{P}(4)-\mathrm{Pt}(3)-\mathrm{P}(5)=151.7\right.$ (2) $\left.{ }^{\circ}\right]$. The ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$, and ${ }^{195} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR data, ${ }^{10}$ including the 2D ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ correlated spectrum needed to assign proton signals, are fully consistent with structure $\mathbf{4}$ and prove that there is no fluxionality of the acetylene ligand.

[^1]It is possible that the reaction proceeds through an acetylide intermediate 5 , which then undergoes rearrangement to give 4. The detailed mechanism is unknown, but, given the basic medium with excess NaCCH present, a multistep process involving deprotonation of a $\mu$-dppm ligand is considered likely. Reaction of 2- $d_{2}$, prepared from DCCD, with NaCCH led to scrambling of the deuterium label amongst the positions at $\mathrm{C}(4), \mathrm{C}(5), \mathrm{C}(6)$, and $\mathrm{C}(7)$. Therefore it is not possible to distinguish between mechanisms in which coupling of dppm with acetylide occurs or in which the carbanion center of a deprotonated dppm ligand attacks coordinated acetylene; the latter is favored by organometallic precedents and by proximity of the functional groups. The formation of 4 appears to be a unique functionalization of a $\mu$-dppm ligand ${ }^{2-4}$ and suggests that a more extensive chemistry, involving coupling of $\mu$-dppm ligands and unsaturated reagents under basic conditions, is probable.

Received August 22, 1988
During the course of our investigations ${ }^{2,3}$ on the superacidcatalyzed isomerization of highly symmetrical undecacyclic $\mathrm{C}_{20} \mathrm{H}_{20}$ hydrocarbon [1.1.1.1] pagodane $1^{4}$ to its structurally closely related isomer, pentagonal dodecahedrane $\mathbf{2},{ }^{5}$ we serendipitously discovered the formation of remarkably stable "pagodane dication" 3. This novel $2 \pi$-electron homoaromatic system can be represented by several resonance structures (e.g., 3a, 3b), but $D_{2 h}$ equilibrium structure $\mathbf{3}$ is stabilized relative to any single localized structure like 3 a due to strong interaction of the two empty p -lobes with a periplanar strained $\mathrm{C}-\mathrm{C} \sigma$-bond. ${ }^{2}$ In this context, we became

interested in the bonding situation of the related 2-secopagodyl monocation 6 which is formally derived from pagodane 1 by protonation of the four-membered ring.

1

All our attempts to protonate pagodane $\mathbf{1}$ to generate cation 6 with superacids, ${ }^{6 a}$ including the newly developed only mildly oxidizing superacid system $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}: \mathrm{B}_{\left(\mathrm{O}_{3} \mathrm{SCF}_{3}\right)_{3} \text {, }{ }^{\text {bb }} \text { were un- }}$ successful. Under all these conditions, dication $\mathbf{3}$ was exclusively formed by rapid two-electron oxidation. In contrast, dissolution of valence isomer bissecododecahedradiene $7^{7}$ in the $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}: \mathrm{B}\left(\mathrm{O}_{3} \mathrm{SCF}_{3}\right)_{3} / \mathrm{SO}_{2} \mathrm{ClF}$ system resulted in the desired monoprotonation, as became evident with the independent generation of the same ion by careful ionization ${ }^{8 \mathrm{aa}}$ of 2-chlorosecopagodane $4^{8 b}$ in a 5 -fold excess of $\mathrm{SbF}_{5}$ in $\mathrm{SO}_{2} \mathrm{ClF}$ at $-78^{\circ} \mathrm{C}$. The $50-\mathrm{MHz}{ }^{13} \mathrm{C}$ NMR spectrum ${ }^{92}$ of each light yellow colored solution showed the same $12{ }^{13} \mathrm{C}$ resonances with relative intensities and multiplicities similar to halide progenitor 4. ${ }^{9 \mathrm{~b}}$ This is in accord with the formation of monocation 6 with (retained) $C_{s}$ symmetry. Seco-cation 6 was also formed on protolytic ionization of seco-
