assumes only a bistable jump by $180^{\circ}$, other internal motions such as rotations by other angles, free rotations, vibrations, and distortions can also occur in a molecule. These need detailed calculations using numerical methods like molecular mechanics and Monte Carlo simulation.

In NOE calculations involving more than two spins, the cross-correlation between the different dipolar vectors often plays a significant role. ${ }^{45}$ When an internal motion is also present apart from the overall motion, the cross-correlation spectral density functions have additional information about the correlation between the two motions. The present model assumes that the global and segmental motions are independent of each other, hence multispin NOE have been calculated in this paper by neglecting the cross-correlation effects.

Acknowledgment. Discussions with Prof. B. D. Nageswara Rao and Prof. P. Balaram, who also provided the peptide sample, are gratefully acknowledged. We thank Profs. C. L. Khetrapal and J. Tropp for perusal of the manuscript. A.K. acknowledges the Department of Science and Technology, India, for a research grant and V.V.K. acknowledges CSIR for a senior research fellowship.

## Appendix: Direction Cosines of the Dipolar Vector in the Internal Frame

The coordinates of the nucleus D (tip of the vector $\bar{F}_{1}$ ) at any time $t$ in the $S_{I}\left(X_{\mathrm{I}}, Y_{\mathrm{I}}, Z_{\mathrm{I}}\right)$ are

# Solution Structure of a Synthetic N-Glycosylated Cyclic Hexapeptide Determined by NMR Spectroscopy and MD Calculations ${ }^{\dagger}$ 

H. Kessler,* H. Matter, G. Gemmecker, A. Kling, and M. Kottenhahn<br>Contribution from the Organisch-Chemisches Institut, Technische Universität München, Lichtenbergstrasse 4, D-8046 Garching, Germany. Received January 17, 1991

#### Abstract

The synthesis and conformational analysis by NMR spectroscopy and MD calculations of the N-glycosylated cyclic hexapeptide cyclo(-D-Pro-Phe-Ala-[ $N$-2-acetamido-2-desoxy- $\beta$-D-glucopyranosyl)]Gln-Phe-Phe-) (I) and the cyclic hexapeptide precursor cyclo(-D-Pro-Phe-Ala-Glu(OtBu)-Phe-Phe-) (II) were carried out to study the influence of N -glycosylation on conformation of peptides. For both compounds, all of the distance constraints derived from 2D NOE measurements could not be satisfied by one conformation. Therefore, second conformers interconverting fast compared to the NMR time scale are assumed. The two conformations differ in the $\beta$-turn structure between Ala ${ }^{3}$ and $\mathrm{Phe}^{6}$ ( $\beta I I$ - or $\beta$ I-turns, respectively). The $\beta I I^{\prime}$-turn about amino acids $\mathrm{D}-\mathrm{Pro}^{1}$ and $\mathrm{Phe}^{2}$ is highly conserved in both MD simulations. The conformations were refined by using restrained MD simulations in vacuo and in water. Additional MD simulations with application of time-dependent distance constraints provide further information about the internal flexibility of $I$. The conformational equilibrium could be confirmed; several conformational changes were detected evidenced by a large number of torsion angle fluctuations during the time scale of the simulation. Both proposed backbone conformers were significantly populated. The averaging over coupling constants and NOE data reveal the high flexibility of the structure and the good agreement with experimental data for both I and II. The N -glycosylation does not affect the conformation or the overall shape of the peptide backbone or side chains. It has no influence on the hydrogen-binding pattern or on the fast dynamical equilibrium of the molecule.

## Introduction

Carbohydrates and glycoproteins are of great importance in biological recognition phenomena. ${ }^{1}$ Therefore, the interest in the synthesis and conformations of glycopeptides as partial structures

[^0]of glycoproteins has increased considerably. ${ }^{2}$ Many applications for glycopeptides are currently being established, e.g., in the development of selective pharmaceuticals and for the improvement of pharmacokinetic properties. ${ }^{3}$

Presently, very little is known about the mutual conformational influences between the protein or peptide structures and the

[^1]

Figure 1. Constitution of glycopeptide 1 and cyclic hexapeptide II.
oligosaccharide moiety linked to one of the amino acid side chains. ${ }^{4}$ Yet conformational analysis is an indispensible tool for understanding the mechanisms of molecular recognition in biological systems. ${ }^{5}$ We have therefore focused our attention on the conformations of glycopeptides.

Nuclear magnetic resonance (NMR) spectroscopy is one of the most effective methods for the investigation of the conformation and internal dynamic properties of biomolecules such as peptides, ${ }^{6}$ proteins, ${ }^{6}$ and glycopeptides. ${ }^{5 a .7}$ The purpose of this paper is to demonstrate how current 2D NMR spectroscopic techniques and molecular dynamics (MD) simulations in vacuo and in solution lead to a detailed insight into the conformational properties of a synthetic N -glycosylated cyclic hexapeptide, cyclo(-D-Pro ${ }^{1}$ Phe ${ }^{2}-$ Ala $^{3}-[N-2$-acetamido-2-desoxy- $\beta$-D-glucopyranosyl)]Gln ${ }^{4}$-Phe ${ }^{5}-$ Phe $^{6}$ ) (I), in comparison to the unglycosylated cyclic peptide cyclo(-D-Pro ${ }^{1}-\mathrm{Phe}^{2}-\mathrm{Ala}^{3}-\mathrm{Glu}^{4}(\mathrm{OtBu})-\mathrm{Phe}^{5}-\mathrm{Phe}^{6}-$ ) (II). This molecule allowed us to study the influence of a monosaccharide moiety linked to a glutamine side chain on conformation and dynamics of the backbone. A cyclic peptide has been chosen because of the considerable reduction of conformational freedom and flexibility.

There are two main reasons why this particular glycopeptide was chosen for the demonstration of direct glycosylation and conformational analysis.
(i) Model compounds of the type cyclo(-D-Pro ${ }^{1}-\mathrm{Phe}^{2}-\mathrm{Ala}^{3}-$ $\mathrm{Xaa}^{4}-$ Phe $^{5}-$ Phe $^{6}$-) (where Xaa stands for an amino acid with side chain functionality, e.g., serine or glutamine) have been used in our group to study glycopeptide synthesis by direct glycosylation of larger peptide fragments. ${ }^{8}$ It turned out that the partial sequence-Phe-D-Pro-Phe-Ala- generally forms a $\beta I^{\prime}$-turn with D-proline in the $i+1$ position of these cyclic hexapeptides. It is well known that cyclic hexapeptides have the tendency to form structures containing two $\beta$-turns. ${ }^{9}$ The strong tendency of a D-Pro residue to adopt the $i+1$ position of a $\beta I^{\prime}$-turn normally

dominates all other effects. ${ }^{10}$ Hence, $\mathrm{Xaa}^{4}$ in our peptides is often in the $i+1$ position of such a $\beta$-turn. The hydroxyl group of a serine ${ }^{11}$ or the carboxyl group of a glutamic acid in this position is exposed to the solvent, which provides an ideal opportunity for a glycosylation of their side chain. The synthesis of $O$ - and N -glycopeptides therefore was a reasonable task.
(ii) The model compound cyclo(-D-Prol${ }^{1}-\mathrm{Phe}^{2}-\mathrm{Ala}^{3}-[N-2-$ acetamido-2-desoxy- $\beta$-glucopyranosyl)]Gln $\left.{ }^{4}-\mathrm{Phe}^{5}-\mathrm{Phe}^{6}-\right]$ was synthesized as a cyclic retro analogue of the peptide hormone somatostatin and the cyclic decapeptide antamanide. Several cyclopeptides similar in structure have been prepared in our group to study their structure-activity relationship as inhibitor of a hepatocytic transport system. ${ }^{12}$ Somatostatin inhibits the secretion of hormones in several tissues such as the hypophysis and pancreas and in the gastrointestinal tract. ${ }^{13}$ In addition, it exhibits an anti-ulcerogenic effect ${ }^{14}$ and is active as an analgesic. ${ }^{15}$ Furthermore, it has been shown that somatostatin can prevent the uptake of various poisons into liver cells. ${ }^{12 d .16}$ The synthesis of

small cyclic peptides has led to conformationally restricted compounds similar to the compounds discussed here, which show a considerably higher potency with higher selectivity for this process than the native hormone. 12

Here we report the synthesis and the conformational analysis of the N -glycosylated cyclic hexapeptide cyclo(-D-Pro ${ }^{1}-\mathrm{Phe}^{2}-$ $\mathrm{Ala}^{3}$-[ $N$-2-acetamido-2-desoxy- $\beta$-glucopyranosyl) $] \mathrm{Gln}^{4}$-Phe ${ }^{5}$ $\mathrm{Phe}^{6}-$ ) (I) and the cyclic hexapeptide cyclo(-D-Pro ${ }^{1}$-Phe ${ }^{2}-$ $\mathrm{Ala}^{3}-\mathrm{Glu}(\mathrm{OtBu})^{4}-\mathrm{Phe}^{5}-\mathrm{Ph}^{6}-$ ) (II) in DMSO- $d_{6}$ solution (Figure 1). To our knowledge, it is the first reported conformation of an N -glycosylated cyclic peptide in solution. The structure is used to study the influence of different glycosylated amino acids in the $i+1$ position of a cyclic hexapeptide $\beta$-turn.

## Synthesis

The linear precursors of the cyclic hexapeptides were prepared by classical solution-phase methods of peptide synthesis (Scheme I). The coupling of the different precursors was achieved by using the mixed anhydride method with isobutyl chloroformate, ${ }^{17}$ the activation of the N -terminal protected compound with EDCI- HCl and $\mathrm{HOBt},{ }^{18}$ or the azide-coupling method. ${ }^{19}$ After the deprotection of the N -terminal amino acid of the linear hexapeptide, this precursor was cyclisized via the azide by the method of Medzihradsky. ${ }^{19}$ Finally the cyclic peptide was purified by semipreparative HPLC and the glutamic acid side chain deprotected with HCl in ether.

N-Glycosylation was achieved by coupling cyclo(-Phe-D-Pro-Phe-Ala-Glu-Phe-) with 2-acetamido-3,4,6-tri-O-acetyl-2-desoxy- $\beta$-D-glucopyranosylamine according to the classical carbodiimide procedure ${ }^{18}$ with EDCI/HOBt in anhydrous THF as solvent. Chromatography of the crude product afforded the O -acetyl-protected N -glycopeptide with $65 \%$ yield in high purity. As with the N -glycosylation of linear peptides, ${ }^{20} \mathrm{HOBt}$ was added as a scavenger to avoid side reactions from the intermediately formed reactive $O$-acylisourea.

Cleavage of the acetyl protecting groups was carried out with KCN in methanol/ethanol, ${ }^{21}$ and subsequent purification by HPLC yielded the deprotected $N$-glycopeptide I ( $81 \%$ ). In both reactions, no epimerization at the anomeric carbon atom of the carbohydrate moiety could be observed.

## NMR Measurements

Evaluation of the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR Spectra of I and II. For the assignment of the ${ }^{1} \mathrm{H}$ resonances, a combination of several 2D NMR techniques was applied for both I and II: In both cases, TOCSY with different mixing times ${ }^{22}$ and DQF-COSY ${ }^{23}$ provided an almost complete assignment of all proton signals. The amino acid residues of both compounds were identified according to their characteristic pattern of chemical shifts based on connectivity from scalar hetero- and homonuclear couplings. The evaluation of an inverse ${ }^{13} \mathrm{C}^{-1} \mathrm{H}$ shift correlation ( $\mathrm{HMQC}{ }^{24}$ ) and a HMQC TOCSY ${ }^{25}$ not only confirmed the proton assignments but in addition allowed the complete assignment of all ${ }^{13} \mathrm{C}$ resonances. This

made it possible to remove ambiguities in the assignment of the sugar protons. The chemical shifts for the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ resonances are given in Table I.
Sequential assignment of the amino acid residues was carried out from the analysis of ROESY ${ }^{26}$ and NOESY ${ }^{27}$ spectra with mixing times of 120 ms . The obtained information was crosschecked and verified in a selective inverse ${ }^{13} \mathrm{C}-{ }^{4} \mathrm{H}$ long-range correlation applied to the carbonyl carbons (HMBC ${ }^{28,29}$ ). As we recently reported, the quality of this correlation for the sequencing and assignment of carbonyl resonances could be improved by using a $270^{\circ}$ Gaussian-shaped pulse ${ }^{29 \mathrm{c}}$ for the semisoft exci-

[^3]

Figure 2. $\mathrm{N} H / \mathrm{C}_{\alpha} \mathrm{H}$ region of the $600-\mathrm{MHz}$ NOESY spectrum ( $120-\mathrm{ms}$ mixing time) of the glycopeptide I in DMSO- $d_{6}$. Only positive contours are shown. Zero quantum contributions are not suppressed, as integration of zero quantum contribution is zero. These signals are easy to recognize by their antiphase appearance.
tation of the $C=0$ resonances because this self-refocusing pulse allows a phase-sensitive recording in $F_{1}$. This experiment is not only important for the assignment of the $C=0$ resonances but can also be applied for a diastereotopic assignment of $\mathrm{C}_{\beta} H$ resonances.

Extraction of Conformationally Relevant NMR Parameters. Only one distinct set of signals was found in the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of II. A second signal set with a population $<1 \%$ could be detected in the ${ }^{1} \mathrm{H}$ NMR spectrum of I, but a detailed examination of this conformation was impossible due to the low signal to noise ratio. It is not clear if this second set of signals is an indication of a second conformation (lack of 2D ROESY exchange peaks) or an impurity (no indication in HPLC analysis). No conformational change slow on the NMR time scale could be determined by line-broadening effects. All other criteria for conformational homogeneity were fulfilled. ${ }^{30}$ However, these observations cannot exclude the occurrence of fast interconverting conformers. It is known that various side chains of amino acids in smaller peptides or cyclopeptides and exocyclic (e.g., glycosidic) bonds of saccharide moieties are not rigid or fixed in one distinct conformation. Often a conformational equilibrium has to be postulated in peptidic backbones as well, where fast dynamical interconversions have been observed. ${ }^{31,32}$ Conformational analysis by NMR spectroscopy on several cyclic pentapeptides as models for reverse turns reveals that two different turn structures ( $\beta \mathrm{I}$ and $\beta$ II-turn) are present in equilibrium. ${ }^{3 l e}$

In fact, it is difficult to decide whether a molecule is conformationally homogeneous or not. However, at the end of the conformational analysis, the results are checked for the validity of the assumption of one dominating conformer. If all NMR data

agree with a unique conformation, then this approach is a sufficient model. ${ }^{31 a, b}$ However, as will be pointed out later, this was not the case here.
Conformational analysis is based on distances between protons derived from proton-proton dipolar interactions. NOESY and ROESY experiments at 600 MHz with mixing times of 120 ms provide quantitative information on interproton distances. They were recorded without zero-quantum suppression. Most of the peak volumes were integrated on both sides of the diagonal; some cross peak intensities could not be determined, mainly due to $t_{1}$ noise. The distances were calculated under the assumption of an isotropic tumbling rigid molecule and by using the isolated two-spin approximation (ISPA). The volume of the cross peak between spins $i$ and $j$ then is proportional to $d_{i j}^{-6} .{ }^{33}$
For assignment of NOE effects from overlapping proton resonances in the N -glycosylated cyclic hexapeptide, HMQCNOESY first described by Shon and Opella for ${ }^{15} \mathrm{~N}$-labeled proteins ${ }^{34}$ was applied. The ${ }^{1} \mathrm{H}$ homonuclear NOE between overlapping proton resonances could be detected with ${ }^{1} \mathrm{H} /{ }^{13} \mathrm{C}$ heteronuclear correlated spectroscopy in natural ${ }^{13} \mathrm{C}$ abundance. This experiment provides the means of establishing protonhomonuclear NOE's resolved by a heteronuclear shift correlation. BIRD presaturation of the ${ }^{12} \mathrm{CH}$ protons and ${ }^{13} \mathrm{C}$ GARP decoupling during the detection period was applied. The application of the HMQC-NOESY to peptides in natural abundance at higher concentration even allows a quantification of the NOE effects. ${ }^{35}$

For the glycopeptide I, we obtained an NOE data set consisting of 57 proton-proton distances (including all NOE's to diastereotopically assigned protons, see Table IV). For calibration of the NOESY integrals, the cross peak between $\mathrm{Phe}^{6} \mathrm{C}_{\beta} H^{\text {pro-R }}$ and Phe ${ }^{6} \mathrm{C}_{8} H^{\text {pro-S }}$ was used. The resulting $\mathrm{N} H-\mathrm{N} H$ distances in comparison with data derived from the ROESY (Table IV, values in parentheses, both were measured at 600 MHz ) exhibit the contribution of chemical exchange to the volume integral of the NOESY/ROESY cross peaks. ${ }^{6 \times 33}$ Chemical exchange increases the value for the NOESY cross peak integral (shortening the derived distance), but decreases the integral value in the measured ROESY spectra-because of the different sign of the NOE/ROE effects for molecules of this size (positive and negative cross peak amplitudes in $600-\mathrm{MHz}$ spectra). Therefore, the NOESY-derived $\mathrm{N} H-\mathrm{N} H$ distances were taken as the lower bounds and the ROESY-derived distances as the upper bounds in the distance constraints term for the refinement procedure described below. However, it was not possible to separate quantitively the contribution of the chemical exchange from the contribution of the dipolar relaxation to get more reliable distances. The experimental error for all other NOE-derived distances was estimated as $5-10 \%$, when distances obtained from NOESY and ROESY experiments were compared.
For II, we obtained 30 distances (including all NOE's to diastereotopically assigned protons) from the 2D NOESY spectrum (Table V). The comparison of observed and calculated distances (40-ps MD trajectory) shows a systematic deviation, also indicated by a high value for the average restrained violation, caused by an incorrect calibration due to experimental inaccuracies. Better agreement between experiment and simulation was observed by shortening all experimental distances by about $5 \%$. We have used the internal consistence of the data set as criterion for an iterative recalibration without employing a precise calibration cross peak.

In addition to NOE's, scalar coupling constants of vicinal nuclei provide conformational information of the involved dihedral angles via the Karplus equations ${ }^{30,36}$ (Table II). The $\mathrm{NH}-\mathrm{C}_{\alpha} \mathrm{H}$ coupling constants were extracted from 1D spectra after resolution enhancement.

[^4]Table I1. Comparison of Experimentally Determined and Calculated ${ }^{3} J\left(\mathrm{~N} H, \mathrm{C}_{\alpha} H\right)$ Coupling Constants (Hz) for I and $11^{a}$

${ }^{\boldsymbol{a}}$ Possible values for the corresponding peptide backbone angles $\varphi$ (deg) are given, obtained from Bystrovs KARPLUS equation. The experimental values are determined from the ID spectrum after resolution enhancement; the calculated values $\left\langle{ }^{3} J_{\text {caled }}\right.$ 〉 are obtained by averaging over MD simulations. The superscript indicates the numbering of the simulation. Compound 1: a, MD1 ${ }^{\text {a }} ; \mathrm{b}, \mathrm{MDl}^{\mathrm{b}} ; \mathrm{c}, \mathrm{MDl}^{\mathrm{c}}$ (with time-dependent distance constraints). Compound II: a, MDII ${ }^{\mathrm{a}} ; \mathrm{b}, \mathrm{MD} \|^{\mathrm{b}}$. $\left({ }^{3} J_{\text {calod }}\right)^{\mathrm{av}}$ indicates the values obtained from averaging over two different simulations, as described in text.

Finally the temperature dependencies of amide proton chemical shifts indicate their inclusion in inter- or intramolecular hydrogen bonds (Table I). ${ }^{30 c}$ As indicated, the large temperature gradients of the NH protons Phe ${ }^{2} \mathrm{~N}^{\alpha} \mathrm{H}, \mathrm{G} \ln ^{4} \mathrm{~N}^{\alpha} \mathrm{H}, \mathrm{G} \ln ^{4} \mathrm{~N}^{\delta} \mathrm{H}$, and $\mathrm{Glc} \mathrm{N}^{2} \mathrm{H}$ are oriented externally. Small coefficients (internal orientation) are found for $\mathrm{Phe}^{6} \mathrm{~N}^{\alpha} \mathrm{H}$ and $\mathrm{Ala}^{3} \mathrm{~N}^{\alpha} \mathrm{H}$. The coefficient for Phe ${ }^{5} \mathrm{~N}^{\alpha} \mathrm{H}$ is in intermediate range.

Conformation of the Side Chains. The populations of different side chain rotamers were determined via coupling constants following standard procedures. ${ }^{37}$ The $\mathrm{C}_{\beta} H-\mathrm{C}_{\alpha} H$ coupling constants for diastereotropic $\mathrm{C}_{\beta}$ protons were extracted from E.COSY spectra ${ }^{38}$ in both cases. For glutamine or glutamic acid, it was not possible to derive these coupling constants due to signal overlap and spin systems with more than three coupled protons.

The diastereotopic assignment of $\mathrm{C}_{8}$ protons was achieved via the inverse COLOC experiment with semisoft excitation of the carbonyls with a Gaussian-shaped $270^{\circ}$ pulse (HMBCS-270 ${ }^{\circ}$. ${ }^{29}$ Extraction of heteronuclear long-range coupling constants is not as easy as in the case of a normal COLOC experiment. ${ }^{37}$ In the latter, the transfer amplitude $I_{i j}$ from proton $i$ to carbon $j$ is modulated by $\sin ^{2}$ of the heteronuclear coupling $J\left(\mathrm{H}^{i}, \mathrm{C}_{j}\right)$, but in the nonrefocused HMBC spectra is modulated only by sin of this coupling. Therefore antiperiplanar and synclinal couplings are better discriminated in the $\mathrm{H}, \mathrm{C}-\mathrm{COLOC}$ spectrum than in HMBC. However, with known $\mathrm{C}_{\alpha} H-\mathrm{C}_{\beta} H$ coupling constants, a calculation of peak intensities yields a reliable discrimination also for HMBC. ${ }^{39}$

The values for the $\mathrm{C}_{\beta} H-\mathrm{C}_{\alpha} H$ coupling constants and the derived side chain conformations under the assumption of staggered conformations ${ }^{40}$ are summarized in Table III.

From the interpretation of NOE effects, no ambiguities were found for diastereotopic assignment. ${ }^{41}$ Another argument for

[^5]Table III. ${ }^{3} J\left(\mathrm{C}_{\alpha} H, \mathrm{C}_{\beta} H\right)$ Coupling Constants ( Hz ) and Calculated Populations for the Side Chain Conformers for I and II ${ }^{a}$

| Compound I |  |  |  |

| $\chi_{1}=-60^{\circ}$ | $83 \%$ | $73 \%$ | $18 \%$ |
| $\chi_{1}=180^{\circ}$ | $5 \%$ | $14 \%$ | $60 \%$ |
| $\chi_{1}=60^{\circ}$ | $12 \%$ | $14 \%$ | $22 \%$ |
|  | Compound II |  |  |
| residue | Phe $^{2}$ | Phe $^{5}$ | Phe $^{6}$ |
| ${ }^{3} J\left(\mathrm{C}_{\alpha} H, \mathrm{C}_{\beta} H^{\text {pro-R }}\right)$ | 11.5 | 11.7 | 4.3 |
| ${ }^{3} J\left(\mathrm{C}_{\alpha}, H, \mathrm{C}_{\beta} H^{\text {pros }}\right)$ | 3.8 | 3.4 | 9.1 |
| $\chi_{1}=-60^{\circ}$ | $83 \%$ | $77 \%$ | $17 \%$ |
| $\chi_{1}=180^{\circ}$ | $7 \%$ | $11 \%$ | $59 \%$ |
| $\chi_{1}=60^{\circ}$ | $10 \%$ | $12 \%$ | $24 \%$ |

${ }^{a}$ The values are obtained from $250-\mathrm{MHz}$ E.COSY spectrum; the populations are calculated by using Pachler's equation. The diastereotopic assignment of $\beta$-protons was achieved via heteronuclear coupling constants and interpretation of NOE data.
the described side chain preference for $\mathrm{Phe}^{6}$ is that the preferred position of the aromatic ring over the pyrrolidine ring system of D-proline causes a large splitting of the two $\mathrm{D}-\mathrm{Pro}{ }^{1}-\mathrm{C}_{\delta} H$ chemical shifts ( $\delta$ ) due to anisotropy effects. ${ }^{12 \mathrm{~h}}$

Conformational Analysis of I and II. Under the incorporation of some characteristic backbone NOE's, a crude model structure could be built on the basis of the experimental derived Phe ${ }^{6} \mathrm{NH}-\mathrm{Ala}^{3} \mathrm{C}=\mathrm{O}$ and $\mathrm{Ala}^{3} \mathrm{NH}-$ Phe $^{6} \mathrm{C}=\mathrm{O}$ hydrogen-binding pattern, forming a $\beta \mathrm{II}^{\prime} / \beta$ II-type structure. Two small NOE's between $\mathrm{G} \ln ^{4} \mathrm{C}_{\alpha} H-\mathrm{Ph}{ }^{5} \mathrm{~N} H$ and $\mathrm{Phe}^{5} \mathrm{C}_{\alpha} H-\mathrm{Phe}{ }^{5} \mathrm{~N} H$ lead to the assumption of a $\beta I I$-turn in this region. The "ideal" values for these $\mathrm{C}_{\alpha} H^{i-1}-\mathrm{N} H^{i}$ and $\mathrm{C}_{\alpha} H^{i}-\mathrm{N} H^{i}$ NOE's in a $\beta$ II-turn are $205-220 \mathrm{pm}$. The observed values here ( 231 and 244 pm , respectively) correspond well to these data.

NOE's in agreement with an assumed additional conformation with $\beta \mathrm{I}$-turn are $\mathrm{Phe}^{5} \mathrm{~N} H-\mathrm{Ala}^{3} \mathrm{C}_{\beta} H$ and $\mathrm{Phe}^{5} \mathrm{~N} H-\mathrm{Phe}^{5} \mathrm{C}_{\beta} H^{\text {pro-S }}$. These NOE's are only possible in $\beta$ I-turn geometry. The homonuclear coupling constants are in agreement with both types of turn structures, so that discrimination at this stage cannot be carried out. The weak HMBC cross peak observed between Glu ${ }^{4} \mathrm{C}=0$ and $\mathrm{Phe}^{5} \mathrm{C}_{\alpha} H$ is in agreement with the $\beta$ II-turn; this ${ }^{3} J(\mathrm{C}, \mathrm{H})$ coupling is only observable when the involved nuclei adopt an antiperiplanar orientation.

In the other moiety of the peptide, the postulated $\beta \mathrm{II}^{\prime}$-turn structure is supported by the characteristic NOE's and homonuclear $J$ coupling constants for this type of structure.

## Structure Refinement by Molecular Dynamics Simulation (MD)

In order to translate the proton-proton distances and other experimental parameters into a three-dimensional molecular structure, restrained and unrestrained molecular dynamics (MD) simulations using the GROMOS program library ${ }^{42}$ was utilized. For generation of the coordinates of the starting structures and interactive modeling, the program insight (BIOSYM) was used. The starting coordinates for the glycopeptide I were taken from a recently obtained structure of the similar cyclic hexapeptide cy-clo(-D-Pro ${ }^{1}-\mathrm{Phe}^{2}-\mathrm{Ala}^{3}-\mathrm{Ser}^{4}-\mathrm{Phe}^{5}-\mathrm{Phe}^{6}-$ ); ${ }^{11}$ the carbohydrate part was connected to the glutamine side chain by computer model building. As starting coordinates for the cyclic hexapeptide II,

fixed in their dominantly populated conformer (Table III). ${ }^{12 c}$
The gromos force field contains parameters for simulations of peptide/protein and nucleic acid structures. Different parameters for this force field are available for calculations under different conditions: in vacuo, ${ }^{42 b}$ in an aqueous environment, ${ }^{42}$ and in an apolar environment. ${ }^{46}$ Earlier MD simulations of different cyclodextrines (a family of cyclic oligosaccharides consisting of six, seven, or eight glucose units) suggest that the GROMOS force field is reliable for MD simulations of oligosaccharides or glycopeptides. ${ }^{47}$ Including the N -2-acetamido2 -desoxy- $\beta$-glucopyranosyl) residue (GlcNAc) in the MD simulations, some new parameters have to be incorporated in the employed force field. These values for the monosaccharide residue are derived from parameters listed in ref 47a.
The kinetic energy was included during the calculations by coupling the whole system to a thermal bath. ${ }^{48}$ All calculations were performed on Silicon Graphics 4D/240SX and 4D/70GTB computers.
The temperature gradients of the chemical shifts of the $\mathrm{N} H$ resonances (Table I) were implemented as described before ${ }^{12 \mathrm{~h}}$ as factors for reducing the charges of the solvent exposed amide protons and nitrogens: Full charge was left at the observed temperature gradient of $-0.9 \mathrm{ppb} / \mathrm{K}$ for $\mathrm{Phe}^{6} \mathrm{~N} H$, whereas for Phe ${ }^{1} \mathrm{~N} H(\Delta \delta / \Delta t=-6.6 \mathrm{ppb} / \mathrm{K})$, a reduction to $25 \%$ was used in the case of I. Intermediate values were linearly interpolated.

[^8]The temperature gradients for the amide protons of the saccharide moiety show that these protons are exposed to the solvent; charge reduction in this case is applied. The same concept was used during the simulation of II. A full effective charge was left for Phe ${ }^{6} \mathrm{~N} H(\Delta \delta / \Delta t=+0.4 \mathrm{ppb} / \mathrm{K})$; the charge values for Phe ${ }^{1} \mathrm{~N} H$ ( $\Delta \delta / \Delta t=-8.0 \mathrm{ppb} / \mathrm{K}$ ) were reduced to $25 \%$. The purpose of this manipulation is to mimic solvent surrounding in in vacuo calculation by experimental data. ${ }^{12 \mathrm{~h}}$

A harmonic restraint potential was employed for upper and lower distance bounds. The distance restraints function switches from harmonic to linear, when the deviation is greater than 10\% from the target distance. The lower bound distances are given in Table IV, obtained from averaging over both sides of the diagonal; for the upper bounds, 100 and 90 pm were added for each methyl and nonstereospecifically assigned $\mathrm{CH}_{2}$ group, respectively, except for $\mathrm{N} H-\mathrm{N} H$ distances, as noted above. ${ }^{42 \mathrm{~b}}$

The starting structure for I was minimized (conjugate gradient algorithm ${ }^{49}$ ) for 1000 steps. Then 1000 steps restrained EM ( $K_{\text {dc }}$ $=5000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}$ ) with SHAKE ${ }^{50}$ were performed. The resulting structure EMI was used as the input structure for different MD simulations. The minimization of II with the same protocol lead to structure EMII.

The MD simulations were performed with the SHAKE procedure; a step size of 2 fs for the numerical integration of Newton's equation (leap-frog algorithm ${ }^{50}$ ) was reasonable.

Refinement Protocol of I. Before averaging over a trajectory, a time span of 10 ps was used to equilibrate the system. Initial velocities for the atoms were taken from a Maxwellian distribution at the corresponding temperature. During the first 1 ps , the system was strongly coupled to a 1000 K temperature bath ${ }^{48}$ with a temperature relaxation time $\tau$ of 0.01 ps and a force constant for the distance restraints of $4000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}\left(K_{\mathrm{dc}}\right)$. In the next 4 ps , the temperature was scaled down to 300 K and the temperature relaxation time was increased to 0.1 ps ; the system was now weakly coupled to the temperature bath. Simultaneously the value for $K_{\mathrm{dc}}$ was decreased to $2000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}$. The next 5 ps was used for equilibration of the system. The resulting structure served as the starting structure for recording a trajectory over a $40-\mathrm{ps}$ time span with $K_{\mathrm{dc}}=2000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}$. During the next 5 ps , the force constant was reduced to $1000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}$; this period was likewise used as an equilibrium period. A $40-\mathrm{ps}$ trajectory was recorded with this reduced force constant (structure $\mathrm{MDI}^{2}$ ). This procedure ( $5-\mathrm{ps}$ equilibrium, $40-\mathrm{ps}$ dynamics) was then repeated without applying any constraints.

When distance constraints with different force constants $K_{\mathrm{dc}}$ are applied, the peptide backbone angles show no large fluctuations. Free MD without distance constraints reveal the tendency of the saccharide unit to compensate its charges by adopting a structure that conflicts with the NMR data.

The final structure MDI ${ }^{\text {a }}$ (averaged over MD simulation) now satisfied 54 distance constraints, while violating 3 NOE distances (Table IV, underlined in Table X). The violations may arise from errors in the experimental parameters. However, in many instances, conformational mobility in the molecule was the cause of such errors, ${ }^{51,52}$ and it was possible to determine these conformations by use of MD simulations, for example, in the case of the cyclic decapeptide antamanide. ${ }^{31}$

Our results for I and II show that the observed NOE data set (including the complete diastereotopic assignment) cannot be satisfied by one conformation; at least two conformations are required. Most of the diastereotopically assigned NOE's are fulfilled so that the fixing of the side chain dihedrals as described before does not produce an error (MD simulations in vacuo without fixing side chains in preferred conformations lead to a physically

[^9]

Figure 3. Stereoview of the mean structure of Peptide I with a $\beta$ II-turn in the $\mathrm{Ala}^{3}$ to $\mathrm{Phe}^{6}$ region, obtained from averaging the 40 -ps trajectory from MDI ${ }^{2}$ (in vacuo). The protons bound to carbon are not shown.
unrealistic picture due to vacuum effects). But in one case (Phe ${ }^{5} \mathrm{NH}-\mathrm{C}_{\beta} \mathrm{H}^{\prime}$ s) the deviation from the calculated distance to the measured one is larger. The relevant NMR parameters (NOE and coupling constants) depend in a nonlinear way on distances and dihedral angles; ${ }^{51}$ short distances are overemphasized by NOE's. It turned out that there is a fast conformational equilibrium between two (or more) conformations which differ in a flip about the $\varphi$ and $\psi$ dihedral angles around the amide bond between Gln ${ }^{4}$ and Phe ${ }^{5}$; this flip caused two different $\beta$-turn structures.

Therefore, we performed in vacuo simulations in a similar manner with different starting conformation (with a $\beta \mathrm{I}$-turn between $\mathrm{Ala}^{3}$ and $\mathrm{Phe}^{6}$, corresponding to a $180^{\circ}$ flip about the $\mathrm{G} \ln ^{4}-\mathrm{Ph}^{5}$ bond). The structure after energy minimization was equilibrated for 5 ps at 300 K with a force constant $K_{\mathrm{dc}}=1000$ $\mathrm{kJ} \mathrm{mol}^{-1} \mathrm{~nm}^{-2}$; then a trajectory over 40 ps with the same force constant was performed. Two NOE's that cannot be satisfied by a $\beta$ I-turn structure in this moiety were omitted from the distance constraint list (marked in Table X).
The distance constraints previously in violation were satisfied by the new averaged conformation MDI ${ }^{\text {b }}$ (MD trajectory over 40 ps ). During the simulation, no conformational change occurred. If we calculate the NMR parameters (NOE data) from both trajectories MDI ${ }^{a}$ and MDI ${ }^{\text {b }}$ (average restraint violation 11 and 10 pm for MDI ${ }^{\mathrm{a}}$ and MDI ${ }^{\mathrm{b}}$, respectively) under the assumption that both conformations are equally populated ( $p_{\mathrm{a}}=p_{\mathrm{b}}=0.5$ ), all NOE distances are satisfied (average restraints violation 9 pm ) and the large deviation of some NOE's vanishes.
The total potential energy of these simulations (as averaged over the 40 -ps trajectory) is given in Table X. The values for the distance restraint energies are also given, but a comparison of the energies naturally suffers from the different numbers of distance constraints applied.
For both structures, the $\beta \mathrm{II}^{\prime}$-turn in the other peptide moiety was not affected from the occurrence of the $\beta$-turn on the counterside of the peptide.

The two different structures shown in Figures 5 and 6 were obtained by averaging over the trajectories and energy minimized for five steps with the same force constant as applied in the trajectory to relax them from physically unrealistic averaging artifacts. The average dihedral angles and observed hydrogen bonds for both structures are given in Tables VI and VIII, respectively.

MD Simulation with Time-Dependent Distance Constraints. To confirm the model of two fast interconverting conformers in I, MD simulations using time-dependent distance restraints ${ }^{53}$ were

The tert-butyl protecting group (not included in calculation) and the protons bound to carbon are not shown.

Figure 6. Stereoview of the mean structure of Peptide II with a $\beta$ I-turn in the Ala ${ }^{3}$ to $\mathrm{Phe}^{6}$ region, obtained from averaging the $40-\mathrm{ps}$ trajectory from MDII ${ }^{\text {b }}$ (in vacuo). The tert-butyl protecting group (not included in calculation) and the protons bound to carbon are not shown.
carried out. This method performs a wider search of conformational space. The NOE data set is not treated as a static additional potential in the force field, but a term is included so that the distance constraints must only be satisfied as a $\left\langle r^{-3}\right\rangle^{-1 / 3}$ weighted time average over a simulated trajectory. A better approximation of the physical nature of the NOE's is achieved that will reflect the conformational equilibrium. ${ }^{53}$ Therefore, this method gives

${ }^{a}$ The numbers in parentheses denote the rms fluctuation obtained by averaging. The $\omega$ dihedrals are given to the next amino acids. ${ }^{b}$ The large observed deviation from planarity is due to averaging over different conformations in MDI ${ }^{e}$ by using time-dependent distance constraints. The large rms fluctuation reflects the flexibility in this region. For details, see text.
a better estimation of the conformational behavior of a flexible molecule in solution.

The EMI structure was used as a starting structure; the integration time step was set to 2 fs . For the simulations with the time-averaged distance restraints, the required initial value was set for each restraint to be 20 pm less than the experimental value. The artificial force is therefore gradually increased for those restraints that have the greatest violation. ${ }^{53 \mathrm{~b}}$ The time constant $\tau$ for the decay of the "memory function" was set to $2.5 \mathrm{ps} .^{54}$ This value directly affects the rate of motion during the simulation and therefore influences the time requirements for the averaging. ${ }^{53 \mathrm{~b}}$ After an initial $10-\mathrm{ps}$ time span for equilibrium (without timedependent distance restraints), a $90-\mathrm{ps}$ MD simulation in vacuo was started with $K_{\mathrm{dc}}=1000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}$.

The observation of two or more fast interconverting conformers could be confirmed after analyzing the trajectory. The distances (Table IV), dihedral angles (Table VI), and the corresponding ${ }^{3} J_{\mathrm{NH}, \mathrm{CaH}}$ coupling constants (Table II), were calculated as an average over all produced different conformations. The average restraint violation (over 57 NOE's) for this simulation is smaller $(9 \mathrm{pm})$ than for simulations without enforcing the distance restraints as a time average; it is in the same range as when averaging over the different conformations (as described above).

The calculated proton-proton distances now agree better with experimentally derived values. The NOE's involving Phe ${ }^{5} \mathrm{NH}$ are

${ }^{a}$ The numbers in parentheses denote the rms fluctuation obtained by averaging. The $\omega$ dihedrals are given to the next amino acids.
better represented during the time scale of the simulation due to the greater flexibility allowed (see for example the three underlined NOE's in Table X). The distance for Phe ${ }^{5} \mathrm{NH}-\mathrm{Ala}^{3} \mathrm{C}^{8} \mathrm{H}$ is not in the allowed range of $322-422 \mathrm{pm}$ (this is only possible during the MDI ${ }^{\text {b }}$ simulation), but the calculated values for the MDI ${ }^{\mathrm{c}}$ and $\mathrm{MDI}_{\mathrm{av}}$ are $80-90 \mathrm{pm}$ smaller than for the $\mathrm{MDI}^{2}$ simulation and show only a deviation of $50-65 \mathrm{pm}$ from the accepted values. The same observations have been made for the other two distances not satisfied in simulation MDI ${ }^{\text {a }}$.

The distance restraint energy for MDI ${ }^{\mathrm{c}}$ is lower than for MDI ${ }^{\mathrm{a}}$ (both calculated with 57 distance restraints), showing the advantage of the application of time-dependent distance constraints. The corresponding energy for MDI ${ }^{\text {b }}$ is calculated for only 55 distance restraints and therefore cannot be compared to the other
values. Considering the accuracy of NOE-derived distance restraints, these approaches produce satisfactory agreement, showing the effectiveness of the new refinement technique for peptides with internal flexibility.

With the ${ }^{3} J_{\mathrm{NH}} \mathrm{CaH}$ coupling constants are calculated as statistical averages over different conformations, the calculated values $\left\langle^{3} J_{\text {calco }}\right\rangle^{\text {av }}$ (for averaging over two conformations) and $\left\langle{ }^{3} J_{\text {calcd }}\right\rangle^{\text {c }}$ (with time-dependent distance constraints) reveal good agreement with experimental data (Table II). The deviation between calculated and experimental values is larger than 1.8 Hz only for Phe ${ }^{6}$. The calculated $J$ values from $\mathrm{MDI}^{\mathrm{a}} / \mathrm{MDI}^{\mathrm{b}}$ cannot fulfill the experimentally derived data as well as when averaging over both conformations, especially when the corresponding dihedral angles are located in backbone regions, which are involved in the dynamic flexibility.

Hence, the interpretation of coupling constants has to be done carefully. A situation with different conformers in dynamic equilibrium, as we have described here, can lead to substantial errors when determining the geometry of reverse turns. The calculation of corresponding dihedral angles is only possible, if these NMR data reflect the conformational behavior of a single conformation. Therefore, coupling constants, often mentioned in the literature as main argument for determination of $\beta$-turn geometries, are in some cases not sufficient to reveal conformational properties because of conformational averaging, which cannot be excluded without performing MD calculations.

After the positional rms fluctuations for the heavy atoms (data not given) or the torsion angle rms fluctuations were analyzed (Table VIII), it was obvious that, for the time-averaged forces, the fluctuations are consistently larger. The rms fluctuations observed of the torsion angles for the $\beta I I^{\prime}$-turn ( $\mathrm{D}-\mathrm{Pro}^{1}-\mathrm{Phe}^{2}$ ) are not significantly larger (1.5-2.0). The fluctuation of the Ala ${ }^{3} \varphi$ angle has increased, in the flexible peptide region, and a large increase of $\operatorname{Gln}^{4} \varphi / \psi$, $\mathrm{Phe}^{5} \varphi / \psi$, and $\mathrm{Ph}^{6} \varphi$ angle fluctuations is observed. This illustrates interconversion of different conformations and therefore the larger available conformational space of the structure resulting from this simulation.

The $\mathrm{Gln}^{4}$ side chain, connecting the saccharide to the peptide unit, shows a greater flexibility; this observation may arise from the increased backbone mobility and the conformational equilibrium.

The glycosidic bond is as flexible as without use of time-averaged restraints. The same observation is made for the carbohydrate geometry except the $\mathrm{C}^{3}-\mathrm{C}^{2}-\mathrm{N}^{2}-\mathrm{C}^{\prime}$ angle, connecting the

${ }^{a}$ Only hydrogen bonds with an occurrence greater than $3 \%$ are displayed. The criterion for a hydrogen bond is the donor hydrogen-acceptor angle must be larger than $90^{\circ}$ and the distance $d_{\mathrm{H}-\mathrm{A}}$ from hydrogen to acceptor smaller than 250 pm .
acetamido function to the saccharide ring system.
Hence, we assume that the MDI ${ }^{\text {a }}$ and MDI ${ }^{\mathrm{b}}$ structures are the major populated conformers in the fast dynamical equilibrium. The course of interconversion and the available conformational space are reflected during the MDIc simulation.

Conformation of the Glycosidic Bond and the Saccharide Unit. The conformations of the N -glycosidic linkage and saccharide moiety are identical in both conformers. The observed trans orientation of $\mathrm{Gln}^{4} \mathrm{~N}_{8} H$ and GlcNAc-C ${ }^{1} H$ indicated by a weak NOE ( 288 pm ) was represented in the MD simulations with a dihedral angle $\mathrm{C}_{5}-\mathrm{N}_{6}-\mathrm{C}^{1}-\mathrm{C}^{2}$ of $140.2^{\circ}$ (21.7) for $\mathrm{MDI}^{\text {a }}, 145.5^{\circ}$ (18.1) for MDI ${ }^{\mathrm{b}}$, and $112.1^{\circ}$ (28.0) for MDI ${ }^{\mathrm{c}}$. The values in parentheses indicate the rms fluctuation obtained by averaging.

These values are in agreement with data from the literature. An X-ray analysis of GleNAc bound to an asparagine residue reveals the same conformational properties of the glycosidic linkage and of the sugar conformation. ${ }^{53}$ As a model compound for the N -glycosidic linkage, $1-N$-Acetyl- $\beta$-D-glucopyranosylamine was analyzed by X-ray and circular dichroism, and the proposed trans orientation for the $\mathrm{C}^{1} \mathrm{H}$ proton of the sugar and the amide proton was confirmed. ${ }^{56}$ This preferred orientation was also previously described for crystalline $\beta$-D-GlcNAc-N-Asn. ${ }^{55}$ X-ray analysis has shown that the glucopyranose rings of GlcNAc-N-Asn and Glc-N-Asn both have the ${ }^{4} C_{1}$ conformation. The glycosidic torsion angles $\mathrm{C}^{\prime}-\mathrm{N}^{1}-\mathrm{C}^{1}-\mathrm{C}^{2}$ (in our definition, $\mathrm{C}_{8}-\mathrm{N}_{8}-\mathrm{C}^{1}-\mathrm{C}^{2}$ ) are $141.0^{\circ}$ and $157.6^{\circ}$ for both of these compounds, corresponding well to our obtained values (see above and Table VI). A trans orientation is also proposed for this glycosidic linkage in larger complex-type oligosaccharides linked to asparagine from the analysis of CD measurement and NMR coupling constants analysis. ${ }^{57}$

Not only the glycosidic bond is trans oriented but also the $\mathrm{N}^{2} \mathrm{H}$ bond of the amide at $\mathrm{C}^{2}$ is trans oriented to the $\mathrm{C}^{2} \mathrm{H}$ bond in $\mathrm{GlcNAc}-\mathrm{N}$-Asn. The corresponding $\mathrm{C}^{3}-\mathrm{C}^{2}-\mathrm{N}^{2}-\mathrm{C}^{\prime}$ angle was given in the literature to be $-125.6^{\circ}$. $55^{3}$ We observed values of $-108.1^{\circ}$ (17.6) and $-101.3^{\circ}$ (16.3) (for MDI ${ }^{\text {a }}$ and MDI ${ }^{\text {b }}$, respectively). The values are in the same range but differ from the simulation with time-dependent distance constraints ( $-66.5^{\circ}$ (66.3)). Here the torsion angle and rms fluctuation reveal a large mobility around the corresponding $\mathrm{C}^{2}-\mathrm{N}^{2}$ bond. Two short distances from GlcNAcN ${ }^{2} H$ to protons on opposite sides of the six-membered ring system (to GlcNAc- $H^{1}$ and to GlcNAc- $H^{2}$ ) were observed and cannot be fulfilled by one rigid conformation of the acetamido group relative to the saccharide. A high violation of these NOE's in all trajectories, except for the final one with time-dependent distance constraints MDI ${ }^{c}$, was observed. These results reflect the internal dynamics in the GIcNAc moiety; the violated distances involving Glc $N \mathrm{Ac}-\mathrm{N}^{2} \mathrm{H}$ show a better agreement to experimental data. The largest observed deviation is 89 pm for the distance $\mathrm{GlcNAc}-\mathrm{N}^{2} \mathrm{H}$ to $\mathrm{Gln}^{4} \mathrm{C}_{\gamma} \mathrm{H}$ (experimental 247-337 pm , not diastereotopically assigned; calculated 426 pm ). This insufficient agreement between experiment and calculation may arise from the increased flexibility of the acetamido group as reflected in our calculations. Therefore, the assumption of isotropic mobility for the correct interpretation of NOE effects may lead to substantial errors for that part of the molecule. However, all other experimental data are in accord with the results from simulation.

The conformation of the saccharide subunit, a ${ }^{4} C_{1}$ chair conformation of the six-membered heterocyclic ring system with all substituents in equatorial position, is also in agreement with previously published results. A force field calculation of $\beta$-Dglucose ${ }^{58}$ suggests that such monosaccharides may undergo changes in their ring conformation with a rotation of up to $10^{\circ}$ in the dihedral angle but with almost no change in energy. The ${ }^{1} C_{4}$ conformation is calculated to have a higher energy content

(about $3 \mathrm{kcal} / \mathrm{mol}$ ) than the ${ }^{4} C_{1}$ conformation. The dihedral angles describing the D -glucose ring conformation obtained from previously described MD simulations correspond well with our results. ${ }^{59}$

MD Simulation of I in Aqueous Solution. The averaged MDI ${ }^{2}$ (with a $\beta$ II-turn in the region between Ala ${ }^{3}$ and Phe ${ }^{6}$ ) was minimized as described in vacuo and put in a box of 545 water molecules in order to test the stability and dynamical properties of the resulted structures. These simulations were performed in water because of a lack of a reliable DMSO force field at this time. Although no experimental data from measurements in water were available, these simulations will better reflect the "realistic" measurement conditions in solution.

A truncated octahedron with a volume of $17.3 \mathrm{~nm}^{3}$ was used. ${ }^{60}$ The water molecules are modeled by the simple rigid three-point charge model (SPC) as described in the literature. ${ }^{61}$ All calculations in water were performed without applying the SHAKE procedure; the time step for integration was reduced to 1 fs . A cutoff radius of 1 nm for the calculation of the nonbonded interactions was used.

The solvent was allowed to relax by 500 steps of EM while the position of the solute atoms was kept fixed by applying a harmonic position restraining potential. The position restraining potential was removed, and another 500 steps of EM was carried out. For both minimizations, no distance restraints were applied. Two MD simulations were performed at 300 K , the first with $K_{\mathrm{dc}}=1000$ $\mathrm{kJ} \mathrm{mol}^{-1} \mathrm{~nm}^{-2}$ for 20 ps (structure MDI ${ }^{11}$ ), the second with no distance restraints for 80 ps .

The stability of the $\beta$ II-type conformer in water was confirmed not only during a time span of 20 ps with application of distance constraints, but also without any constraints. No conformational changes could be detected in water; this observation is in contradiction with results from in vacuo simulations. While examination of the in vacuo simulation without distance constraints suggests the glycopeptide to be a relatively flexible molecule, this flexibility could not be confirmed during simulation in water. These observations can suffer from the applied short simulation times ( 80 ps ) due to the high viscosity of the solvent; a detailed description of conformational behavior in solution is not possible. Nevertheless, the observation of some conformational transitions was often observed during short simulation periods in water. ${ }^{62}$

Refinement Protocol of II. The conformational analysis of II, the building of the crude model structure, and refinement produced similar results as found for I.

All simulations for II were performed in vacuo. With the minimized structure EMII, a $10-\mathrm{ps}$ time span for equilibration with $K_{\mathrm{dc}}=4000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}$ was used during the first 1 ps , $K_{\mathrm{dc}}=2000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-2}$ during the next 4 ps , and $K_{\mathrm{dc}}=1000$ $\mathrm{kJ} \mathrm{mol}{ }^{-1} \mathrm{~nm}^{-2}$ during the next 5 ps . With the resulting structure, a trajectory over a time span of 40 ps was recorded. The temperature relaxation time and all other parameters were treated as described before.

As for the glycopeptide, not all NOE's could be satisfied by assuming only one conformation. Therefore, we have chosen the same approach as for the refinement of $I$.
(i) Two simulations were performed with restraining of the side chain $\chi_{1}$ dihedrals (full diastereotopic assignment of all NOE data) starting from alternate conformations with $\beta \mathrm{II}$-turn or $\beta \mathrm{I}$-turn between $\mathrm{Ala}^{3}$ and $\mathrm{Phe}^{6}$; the resulting structures were named MDII ${ }^{\text {a }}$ and MDII ${ }^{\text {b }}$, respectively.
(ii) Calculation of the NMR parameters (NOE data) from both trajectories was performed under the assumption that both conformations are equally populated.

Also in this case we omitted two NOE's, which cannot be satisfied by a conformation including a $\beta \mathrm{I}$-turn between $\mathrm{Ala}^{3}$ and

Three-Center Hydrogen Bonds in the Cyclic Hexapeptide II

| donor | acceptor 1 acceptor 2 | MDII ${ }^{\text {a }}$ |  |  | MDII ${ }^{\text {b }}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\theta_{\text {DH-AI }}$ <br> $\theta_{\text {DH-A } 2}$ | $\begin{aligned} & d_{\mathrm{D}-\mathrm{A} 1} \\ & d_{\mathrm{D}-\mathrm{A} 2} \end{aligned}$ | \% ${ }_{\text {all }}$ | $\begin{aligned} & \theta_{\mathrm{DH}-\mathrm{Al}} \\ & \theta_{\mathrm{DH}-\mathrm{A} 2} \end{aligned}$ | $\begin{aligned} & d_{\mathrm{DAI}} \\ & d_{\mathrm{D}-\mathrm{A} 2} \end{aligned}$ | \% ${ }_{\text {ell }}$ |
| Phe ${ }^{6} \mathrm{NH}$ | Ala ${ }^{3} \mathrm{C}=0$ | 135.3 | 297 |  | - | - | - |
|  | Glu ${ }^{4} \mathrm{C}=0$ | 131.5 | 301 | 22.5 |  |  |  |
| Ala ${ }^{3} \mathrm{NH}$ | Phe ${ }^{6} \mathrm{C}=0$ | 138.4 | 315 |  | - | - | - |
|  | D-Pro ${ }^{1} \mathrm{C}=0$ | 130.2 | 325 | 8.0 |  |  |  |

${ }^{a}$ Only hydrogen bonds with an occurrence greater than $3 \%$ are displayed. The criterion for a hydrogen bond is the donor hydrogen-acceptor angle must be larger than $90^{\circ}$ and the distance $d_{\mathrm{H}-\mathrm{A}}$ from hydrogen to acceptor smaller than 250 pm .

Phe ${ }^{6}$. The results for the NOE's with the largest violation are given in Table X .
The resulting structures for both conformers are given in Figures 5 and 6; each is obtained after averaging over a $40-\mathrm{ps}$ time span and 5 steps of EM (with the same $K_{\mathrm{dc}}$ as in the simulation). The comparison between experimental and calculated distances, the dihedral angles, and the hydrogen bonds are given in Tables V , VII, and IX, respectively.

Comparison of the Structures for the Glycopeptide and the Cyclic Hexapeptide. It has been shown that $\mathbf{N}$-glycosylation does not affect the conformation or the overall shape of the peptide backbone or side chains. A fast dynamical interconversion between two major conformers in equilibrium differing by the type of the $\beta$-turn was observed for both compounds.

Comparison of the two different hexapeptide conformers with the corresponding glycopeptide conformers shows a great similarity. The dihedral angles of the different peptide conformers are identical with the corresponding glycopeptide conformers. The comparison of the glutamic acid to the glutamine in the glycopeptide shows the greatest deviations caused by the lack of NOE-derived distance data for the fixing of this side chain; therefore, an exact structural analysis of this side chain conformation in II is impossible.

We could not observe any change of the peptide backbone structure, conformation of side chains, hydrogen-bonding pattern, or fast dynamical equilibrium caused by N -glycosylation. A quite similar set of NOE data leads after MD refinement of the crude structures to the same set of two backbone conformers for I and II, respectively.

A comparison between the molecular mobility during the MD simulations of I and II (positional or torsion angle rms fluctuations) further shows that N -glycosylation has no significant effect on the peptide backbone mobility. Comparing MDI ${ }^{\mathrm{b}}$ with MDII ${ }^{\mathrm{b}}$, only the Glu ${ }^{4} \varphi / \psi$ angles show increased mobility (3-4 times). All other fluctuations are in the same range. This is also observed from the comparison of the simulation $\mathrm{MDI}^{\mathrm{a}} / \mathrm{MDII}^{\mathrm{a}}$. The mobility of the Gln ${ }^{4}$ side chain decreased when compared with the Glu ${ }^{4}$ mobility in the cyclic hexapeptide, but this effect seems to be an artifact from applying different distance constraints for the side chains.

## Experimental Section

a. Synthesis. General Procedures. The protected amino acid derivatives were prepared as described in the literature. All intermediates were characterized by TLC, melting point, specific rotation, and ${ }^{1} \mathrm{H}$ NMR. Melting points were determined on a Tottoli melting point apparatus and are uncorrected. Thin-layer chromatography was carried out on Merck silica gel GF 254 plates; the following solvent systems were used: (A) $n$-butanol/ $\mathrm{H}_{2} \mathrm{O} /$ acetic acid (3:1:1); (B) chloroform/methanol

${ }^{a}$ For the notation of the different MD trajectories, please see text. For each simulation, the average restraint violation (pm), the total potential energy $E_{\text {tot pot }}\left(\mathrm{kJ} \mathrm{mol}^{-1}\right)$, and the energy of the distance restraints $E_{\text {dii }}(\mathrm{kJ}$ $\mathrm{mol}^{-1}$ ) are denoted, obtained by averaging over the corresponding simulations. ${ }^{b}$ Increased by 100 pm for MD run ( $\mathrm{CH}_{3}$ group (ref 42 b )). c Increased by 90 pm for MD run ( $\mathrm{CH}_{2}$ without diastereotopic assignment (ref 42 b )). 'NOE's omitted in the MD runs MD1b and MDII ${ }^{\mathrm{b}}$ (see text).
(9:1); (C) chloroform/methanol/acetic acid (95:5:3).
Boc-d-Pro-Phe-OMe (III) (MW = 376.45). To a stirred and cooled $\left(-15^{\circ} \mathrm{C}\right)$ solution of Boc-D-Pro-OH ( $6.5 \mathrm{~g}, 30 \mathrm{mmol}$ ) in anhydrous $\mathrm{CHCl}_{3}$ /DMA ( $75 \mathrm{~mL}, 2+1$ ), subsequently, 1 equiv of NMM ( 3.3 mL , 30 mmol ) and 1.1 equiv of isobutyl chloroformate ( $4.27 \mathrm{~mL}, 33 \mathrm{mmol}$ ) were added. After $30-45 \mathrm{~min}\left(-15^{\circ} \mathrm{C}\right)$, a precooled solution of H -Phe-OMe $\cdot \mathrm{HCl}(6.5 \mathrm{~g}, 30 \mathrm{mmol})$ in anhydrous $\mathrm{CHCl}_{3} / \mathrm{DMA}(75 \mathrm{~mL}$, $2+1)$ containing NMM ( $3.3 \mathrm{~mL}, 30 \mathrm{mmol}$ ) was added. The obtained reaction mixture maintained at $-10^{\circ} \mathrm{C}$ for 1 h was then allowed to warm to room temperature. After completion of the reaction (TLC control), the mixture was concentrated under reduced pressure (bath temperature $40-45^{\circ} \mathrm{C}$ ), taken up in ethyl acetate ( 30 mL ), and cooled to $4^{\circ} \mathrm{C}$. The salts were filtered off, and the organic layer was subsequently washed with aqueous I N HCl , saturated $\mathrm{NaHCO}_{3}$, and saturated NaCl solution
and finally dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After concentration under reduced pressure, the oily residue was taken up in $\mathrm{CHCl}_{3}$ and crystallization was initialized by adding dropwise petroleum ether ( $50-70^{\circ} \mathrm{C}$ ), producing white crystals ( $7.9 \mathrm{~g}, 70 \%$ ). Mp: $106-107^{\circ} \mathrm{C}$. $[\alpha]_{\mathrm{D}}{ }^{20} ; 40.9^{\circ}$ (c 1 in methanol). $R_{f}$ : A, $0.77 ;$ B, $0.67 ; \mathrm{C}, 0.69$. 'H NMR (DMSO- $d_{6}$ ): two sets of signals according to the two rotamers of the urethane $\mathrm{NH}-\mathrm{CO}$ bond; $8.33+8.2$ (each d, 1 H , Phe-NH); 7.16-7.33 ( $\mathrm{m}, 5 \mathrm{H}$, aromatic protons); 4.6 ( $\mathrm{m}, 1 \mathrm{H}$, Phe- $\alpha$ ); 4.05 (m, 1 H, Pro- $\alpha$ ); $3.66+3.61$ ( $\mathrm{s}, 3$ $\mathrm{H}, \mathrm{OMe}$ ); 3.13-3.33 (m, $2 \mathrm{H}, \mathrm{Pro}-\delta$ ); $3.08+2.9$ (each m, 2 H, Phe- $\beta$ ); 1.8-2.02, 1.63-1.73, 1.35-1.5 (each m, $4 \mathrm{H}, \mathrm{Pro}-\beta$ and - $\gamma$ ); $1.4+1.3$ (each s $(2+1), 9 \mathrm{H}, \mathrm{tBu}) \mathrm{ppm}$.

H-D-Pro-Phe-OMe-TFA (IV) (MW = 390.36), To a stirred solution of III ( $8 \mathrm{~g}, 21.24 \mathrm{mmol}$ ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(32 \mathrm{~mL})$, TFA ( 32 mL ) was added dropwise and the reaction mixture stirred for 30 min . The solution was concentrated under reduced pressure (bath temperature below $40^{\circ} \mathrm{C}$ ) and coevaporated with toluene (twice, 30 mL ) and acetone $(30 \mathrm{~mL}$ ). The oily residue was taken up in a small amount of diethyl ether and crystallized by adding petroleum ether ( $50-70^{\circ} \mathrm{C}$ ). After drying in vacuo with KOH , a white amorphous solid was obtained (7.77 $\mathrm{g}, 93.7 \%) . \mathrm{Mp}: 127-129^{\circ} \mathrm{C} .[\alpha]_{\mathrm{D}}{ }^{20}: 21.35$ ( $c 1$ in methanol). $R_{f:} \mathrm{A}$, $0.53 ; \mathrm{B}, 0.31 ; \mathrm{C}, 0.23 .{ }^{1} \mathrm{H}$ NMR (DMSO-d ${ }_{6}$ ): 9.08 (br, $2 \mathrm{H}, \mathrm{NH}_{2}{ }^{+}$); 7.15-7.35 (m, 5 H, aromatic protons); 4.65 (m, 1 H, Phe- $\alpha$ ); 4.19 (m, $1 \mathrm{H}, \operatorname{Pro}-\alpha$ ); 3.68 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{OMe}$ ); 3.05-3.21 (m, $3 \mathrm{H}, \operatorname{Pro}-\delta+$ one Phe- $\beta$ ); 2.89 ( $\mathrm{m}, 1 \mathrm{H}$, second Phe- $\beta$ ); $2.13+1.42$ (each m, 2 H, Pro- $\gamma$ ); $1.79+$ 1.63 (each m, 2 H, Pro- $\beta$ ) ppm.

Z-Phe-D-Pro-Phe-OMe (V) (MW = 557.65). Z-Phe-OH ( 1.38 g , 4.55 mmol ) and IV ( $1.38 \mathrm{~g}, 4.5 \mathrm{mmol}$ ) were dissolved in anhydrous THF ( 24 mL ) containing NMM ( $0.55 \mathrm{~mL}, 5 \mathrm{mmol}$ ). The solution was cooled to $-10^{\circ} \mathrm{C}$ and subsequently mixed with $\mathrm{HOBt}(0.61 \mathrm{~g}, 4.5 \mathrm{mmol}$, EDCI $\cdot \mathrm{HCl}(1.13 \mathrm{~g}, 5.85 \mathrm{mmol})$ and NMM ( $0.55 \mathrm{~mL}, 5 \mathrm{mmol})$. After stirring for 1 h at $-10^{\circ} \mathrm{C}$, the mixture was warmed to room temperature and the reaction continued until completion (TLC control). The solution was concentrated under reduced pressure (bath temperature below 45 ${ }^{\circ} \mathrm{C}$ ), taken up in ethyl acetate ( 35 mL ), and cooled to $4^{\circ} \mathrm{C}$. The salts were filtered off, and the organic layer was subsequently washed with aqueous i N HCl , saturated $\mathrm{Na} \mathrm{HCO}_{3}$, and saturated NaCl solution and finally dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After concentration under reduced pressure to a volume of ca. 8 mL , diethyl ether/petroleum ether $(1+10)$ was added until the solution became cloudy. Rapid crystallization took place, and the obtained product was dried in vacuo over $\mathrm{P}_{2} \mathrm{O}_{\mathrm{s}}$, leaving a white amorphous solid $(2.28 \mathrm{~g}, 91 \%)$. $\mathrm{Mp}: 121-122^{\circ} \mathrm{C} .[\alpha]_{\mathrm{D}}{ }^{20}$ : $59.44^{\circ}(c$ 1 in methanol). $R_{f}: \mathrm{A}, 0.87 ; \mathrm{B}, 0.73 ; \mathrm{C}, 0.68$. ${ }^{1} \mathrm{H}$ NMR (DMSO- $d_{6}$ ): two sets of signals according to the two rotamers of the urethane $\mathrm{NH}-\mathrm{CO}$ bond; 8.78, 7.96, 7.74 (each d, $2 \mathrm{H}, \mathrm{NH}$ signals); 7.1-7.35 (m, 15 H , aromatic protons); 4.93 (dd), 4.91 (s), ( $2 \mathrm{H}, \mathrm{CH}_{2}-\mathrm{Z}$ group); $4.78,4.45$, 4.21, 4.04, 3.91 (each m, $3 \mathrm{H}, \alpha$-protons); 3.6 (s, $3 \mathrm{H}, \mathrm{OMe}$ ); $3.3+3.58$ (each m, $2 \mathrm{H}, \operatorname{Pro}-\delta$ ); 2.68-3.2 ( $2 \times \mathrm{dd}, 4 \mathrm{H}$, all Phe- $\beta$ ); 2.03, 1.45-1.73, 1.4 (each m, 4 H, Pro $-\beta$ and $-\gamma$ ) ppm.

Z-Phe-D-Pro-Phe- $\mathrm{N}_{2} \mathrm{H}_{3}(\mathrm{VI})(\mathbf{M W}=557.65) . \mathrm{V}(4 \mathrm{~g}, 7.16 \mathrm{mmol})$ was dissolved in absolute methanol ( 22 mL ) and hydrazine monohydrate $(7 \mathrm{~mL}, 143.6 \mathrm{mmol}$ ) added with stirring. After 10 h , the resulting suspension was concentrated under reduced pressure and further coevaporated with toluene ( 25 mL , six times) to remove excess hydrazine. The solid residue was dissolved in methanol and treated with water under stirring. The obtained amorphous solid was dried under vacuum over $\mathrm{P}_{2} \mathrm{O}_{5}(3.73 \mathrm{~g}, 93 \%) . \mathrm{Mp}: 111-113^{\circ} \mathrm{C}$. $[\alpha]_{\mathrm{D}}{ }^{20}: 35.49$ ( $c 0.8$ in methanol). Rf: A, $0.78 ; \mathrm{B}, 0.49 ; \mathrm{C}, 0.44$. ${ }^{1} \mathrm{H}$ NMR (DMSO-d ${ }^{6}$ ): two sets of signals according to the two rotamers of the urethane $\mathrm{NH}-\mathrm{CO}$ bond; $8.49+8.0$ (each d, 1 H, Phe ${ }^{3}$-NH); $7.68+7.62$ (each d, 1 H, Phe ${ }^{1}$-NH); 7.08-7.38 (m, 15 H , aromatic protons); 4.84-5.05 (m, $2 \mathrm{H}, \mathrm{CH}_{2}-\mathrm{Z}$ group); 4.82, 4.45 (each m, 2 H, Phe $^{1.3}-\alpha$ ); $4.16+4.0$ (each m, 1 H , Pro- $\alpha$ ); $3.52+3.28$ (each m, 2 H, Pro- $\delta$ ); $2.48-3.18$ (m, 4 H , all Phe- $\beta$ ); 1.2-2.05 (m, 4 H, Pro- $\beta$ and - $\gamma$ ); 8.9 and 4.1-4.4 (hydrazide), ppm.

Z-Glu(OtBu)-Phe-OMe (VII) (MW = 498.57). Z-Glu(OtBu)OH.DCHA ( $2.18 \mathrm{~g}, 3.77 \mathrm{mmol}$ ) was dissolved in ethyl acetate ( 20 mL ) and $20 \%$ aqueous solution of citric acid ( 10 mL ) added. The two-phase system was stirred vigorously and then separated. The organic layer was concentrated under reduced pressure, and the oily residue was dried in vacuo over $\mathrm{P}_{2} \mathrm{O}_{5}$. The dried $\mathrm{Z}-\mathrm{Glu}(\mathrm{OtBu})-\mathrm{OH}$ was dissolved in anhydrous THF/DMA ( $20 \mathrm{~mL}, 1+1$ ) and cooled to $-15^{\circ} \mathrm{C}$. NMM ( 0.46 $\mathrm{mL}, 4.15 \mathrm{mmol}$ ) and isobutyl chloroformate ( $0.54 \mathrm{~mL}, 4.15 \mathrm{mmol}$ ) were added, and the mixture was stirred for 30 min at $-15^{\circ} \mathrm{C}$. A solution of H-Phe-OMe/p-TsOH ( $1.32 \mathrm{~g}, 3.77 \mathrm{mmol}$ ) in anhydrous THF ( 20 mL ) containing NMM ( $0.46 \mathrm{~mL}, 4.15 \mathrm{mmol}$ ) was cooled to $-15^{\circ} \mathrm{C}$ and added to the reaction mixture. After 1 h of stirring at $-10^{\circ} \mathrm{C}$, the solution was allowed to warm to room temperature. Stirring was continued until completion of the reaction (TLC control): The reaction mixture was concentrated in vacuo and taken up in ethyl acetate ( 30 mL ). The suspension was cooled to $4^{\circ} \mathrm{C}$, the salts were filtered off, and the organic layer was subsequently extracted with aqueous 1 N HCl , saturated
$\mathrm{NaHCO}_{3}$, and saturated NaCl solution and then dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$ The ethyl acetate layer was concentrated to a volume of 10 mL . Dropwise addition of isohexane with stirring afforded crystallization of the desired product ( $1.05 \mathrm{~g}, 55.6 \%$ ). Mp: $82-85^{\circ} \mathrm{C}$. $[\alpha]_{\mathrm{D}}{ }^{20}:-12.68^{\circ}$ (c 0.9 in methanol). R; A, $0.85 ;$ B, $0.68 ; \mathrm{C}, 0.73{ }^{1}{ }^{1} \mathrm{H}$ NMR (DMSO-d ${ }_{6}$ ): 8.29 (d, 1 H, Phe-NH); 7.28 (d, 1 H, Glu-NH); 7.13-7.43 (m, 10 H , aromatic protons); 5.02 (s, $2 \mathrm{H}, \mathrm{CH}_{2}-\mathrm{Z}$ group); 4.48, 4.02 (each $\mathrm{m}, 2$ $\mathrm{H}, \alpha$-protons); 3.59 (s, $3 \mathrm{H}, \mathrm{OMe}$ ); 3.0 ( $2 \times \mathrm{dd}, 2 \mathrm{H}$, Phe- $\beta$ ); 2.18 (m, $2 \mathrm{H}, \mathrm{Glu}-\gamma$ ); 1.6-1.9 (m, $2 \mathrm{H}, \mathrm{Glu}-\beta$ ); 1.39 (s, $9 \mathrm{H}, \mathrm{OtBu}$ ) ppm.

Z-Ala-Glu(OtBu)-Phe-OMe (VIII) (MW = 569.65). A solution of VII ( $1.6 \mathrm{~g}, 3.2 \mathrm{mmol}$ ) in anhydrous methanol ( 40 mL ) was hydrogenated with $\operatorname{Pd} 10 \%$ on charcoal ( 400 mg ) as catalyst under standard procedure. After completion of the reaction (TLC control eluent B, $R$ (product) 0.7 ), the catalyst was filtered off and the organic layer evaporated. The oily residue was coevaporated with toluene (twice, 30 mL ) and used for coupling without further purification. Z-Ala-OH ( $692 \mathrm{mg}, 3.1 \mathrm{mmol}$ ) and NMM ( $0.45 \mathrm{~mL}, 3.5 \mathrm{mmol}$ ) were dissolved in anhydrous THF ( 10 mL ) and cooled to $-15^{\circ} \mathrm{C}$, and isobutyl chloroformate ( $0.44 \mathrm{~mL}, 3.4$ mmol ) was added. The reaction mixture was stirred for 30 min at -10 ${ }^{\circ} \mathrm{C}$, the cooled solution of the above hydrogenation product in anhydrous DMA ( 15 mL ) was added, stirred for 1 h , and allowed to warm to room temperature, and after completion of the reaction (TLC control) the solution was concentrated under reduced pressure. The residue was taken up in $\mathrm{CHCl}_{3}$ ( 30 mL ), and the organic layer was subsequently washed with aqueous I N HCl , saturated $\mathrm{NaHCO}_{3}$, and saturated NaCl solution. Further concentration to 6 mL volume and addition of isohexane afforded crystallization of the product as a white solid ( $1.52 \mathrm{~g}, 86 \%$ ). Mp: $138-139{ }^{\circ} \mathrm{C}$. $[\alpha]_{\mathrm{D}}{ }^{20}$; $-26.6^{\circ}$ ( $c 0.6$ in methanol). $R$; A, 0.67 ; B, 0.67 ; C, 0.64. ${ }^{1} \mathrm{H}$ NMR (DMSO- $d_{6}$ ): 8.3, 7.88 (each d, each 1 H , Phe,GluNH); 7.45 (d, $1 \mathrm{H}, \mathrm{Ala}-\mathrm{NH}$ ); 7.12-7.45 (m, 10 H , aromatic protons); 5.01 (s, $2 \mathrm{H}, \mathrm{CH}_{2}-\mathrm{Z}$ group); 4.48, 4.29, 4.05 (each m, each $1 \mathrm{H}, \alpha$ protons); 3.59 (s, $3 \mathrm{H}, \mathrm{OMe}$ ); 3.0 ( $2 \times \mathrm{dd}, 2 \mathrm{H}$, Phe- $\beta$ ); 2.2 (m, 2 H , Glu- $\gamma$ ); 1.5-1.95 (m, $2 \mathrm{H}, \mathrm{Glu}-\beta$ ); 1.38 (s, $9 \mathrm{H}, \mathrm{OtBu}$ ); 1.15 (d, 3 H , Ala- $\mathrm{CH}_{3}$ ) ppm.
Z-Phe-D-Pro-Pbe-Ala-Glu(OtBu)-Phe-OMe (IX) (MW =961.12). A solution of VIII ( $1.3 \mathrm{~g}, 2.28 \mathrm{mmol}$ ) in anhydrous methanol $(50 \mathrm{~mL})$ was hydrogenated with Pd $10 \%$ on charcoal ( 290 mg ) as catalyst under standard procedures. After completion of the reaction (TLC control eluent $\mathrm{B}, R_{\ell}$ (product) 0.7 ), the catalyst was filtered off and the organic layer evaporated. The oily residue was coevaporated with toluene (twice, 30 mL ) and used for coupling without further purification. VI ( 1.26 g , 2.25 mmol ) was dissolved in anhydrous DMA ( 13 mL ) and cooled to -20 ${ }^{\circ} \mathrm{C}$. HCl ( $36 \%$ in water, $0.9 \mathrm{~mL}, 5 \mathrm{~mol}$ equiv) was carefully added and the solution cooled to $-20^{\circ} \mathrm{C}$ before isopentyl nitrite ( $0.5 \mathrm{~mL}, 3.71$ mmol ) was quickly added. The reaction mixture was kept dry and dark with stirring for $1.5 \mathrm{~h} \mathrm{at}-10^{\circ} \mathrm{C}$, and then the precooled solution of the above hydrogenation product in anhydrous DMA ( 10 mL ) containing DIPEA ( $3.5 \mathrm{~mL}, 20.41 \mathrm{mmol}$ ) was added (resulting pH of the solution 7.5-8). After standing for 12 h at $4^{\circ} \mathrm{C}$, the reaction mixture was concentrated under reduced pressure and the resulting residue was taken up in $\mathrm{CHCl}_{3}$ ( 50 mL ). Subsequent washing of the organic layer with aqueous 1 N HCl , saturated $\mathrm{NaHCO}_{3}$, and saturated NaCl solution afforded after evaporation of the organic layer a crude product that could be recrystallized from methanol by addition of water ( $2 \mathrm{~g}, 92.5 \%$ ). Mp: $104-105^{\circ} \mathrm{C}$. $[\alpha]_{\mathrm{D}}{ }^{20}: 4.4^{\circ}(c 0.4$ in DMF). $R$; A, $0.68 ; \mathrm{B}, 0.78 ; \mathrm{C}, 0.67$. ${ }^{1}$ H NMR (DMSO- $d_{6}$ ): two sets of signals according to the two rotamers of the urethane $\mathrm{NH}-\mathrm{CO}$ bond.
Cyclo[-D.Pro ${ }^{1}-\mathrm{Phe}^{2}-\mathrm{Ala}^{3}$ - $\mathrm{Glu}(\mathrm{OtBu})^{4}-\mathrm{Phe}^{5}-\mathrm{Phe}^{6}-$ ] (II) (MW $=$ 794.95). The fully protected hexapeptide IX ( $1.5 \mathrm{~g}, 1.56 \mathrm{mmol}$ ) was dissolved in anhydrous methanol ( 19 mL ) and stirred with hydrazine monohydrate ( $1.53 \mathrm{~mL}, 31.2 \mathrm{mmol}$ ) for 16 h . The resulting suspension was evaporated and further coevaporated with toluene ( $30 \mathrm{~mL}, 3-4$ times) to remove excess hydrazine. The crude product was suspended in methanol/acetic acid ( $50 \mathrm{~mL}, 2+1$ ) and hydrogenated with Pd $10 \%$ on charcoal ( 300 mg , dried) as catalyst. After completion of the reaction (TLC control eluent B), the now clear solution was filtered and concentrated to dryness. The crude product was dried over $\mathrm{P}_{2} \mathrm{O}_{5}$ under vacuum; it showed no more signal for protecting groups in NMR spectra. The deprotected hexapeptide was dissolved in anhydrous DMF ( 11.5 mL ) and cooled to $-20^{\circ} \mathrm{C}$. After careful addition of $\mathrm{HCl}(36 \%$ in water, 0.58 $\mathrm{mL}, 7.23 \mathrm{mmol})$, isopentyl nitrite ( $0.32 \mathrm{~mL}, 2.39 \mathrm{mmol}$ ) was added. The reaction stood dry and dark at $-10^{\circ} \mathrm{C}$ for 1.5 h . The reaction mixture was added to a stirred and cooled ( $-18{ }^{\circ} \mathrm{C}$ ) vessel containing 2 L of anhydrous DMF. The pH of the solution was adjusted to $7.5-8$ by adding DIPEA (ca. 8 mol equiv, 3.72 mL ) and stored for 5 days at $4^{\circ} \mathrm{C}$. The organic layer was evaporated (bath temperature below $45^{\circ} \mathrm{C}$ ) and the oily residue taken up in methanol/water $(60 \mathrm{~mL}, 5+1)$ and shaked with ion exchange resin (Merck-Mischbett, 15 g ). The layer was evaporated in vacuo and the resulting residue recrystallized from $\mathrm{CHCl}_{3} /$ diethyl ether. The obtained amorphous solid was subsequently treated

with aqueous saturated $\mathrm{NaHCO}_{3}$ and 0.5 N HCl solution and water, giving after drying in vacuo the pure product ( $1.0 \mathrm{~g}, 80.6 \%$ ). Mp: $116-118^{\circ} \mathrm{C}$. $[\alpha]_{\mathrm{D}}{ }^{20}:-43.92^{\circ}\left(c 0.5\right.$ in methanol). $R_{\text {: }} \mathrm{A}, 0.79 ; \mathrm{B}, 0.58$; $\mathrm{C}, 0.54$. FAB-MS: $m / e 795\left(\mathrm{M}+\mathrm{H}^{+}\right)$. NMR data are given in Table I.

Cyclo[-D-Pro ${ }^{1}$-Phe ${ }^{2}$-Ala ${ }^{3}$ - Glu $^{4}-$ Phe $^{5}-$ Phe $^{6}$-] (X) (MW = 738.84). The cyclic hexapeptide VIII ( $300 \mathrm{mg}, 0.377 \mathrm{mmol}$ ) was stirred in an ice cold solution of $\mathrm{HCl}_{\text {gab }}$ in diethyl ether ( 90 mL ) for 30 min . The organic layer was evaporated and the white solid residue coevaporated with toluene ( 30 mL , twice). The product was dried over KOH under vacuum, giving white crystals ( 277 mg , quantitative). Mp: $137-138^{\circ} \mathrm{C}$. $[\alpha]_{\mathrm{D}}^{20}:-43.38$ (c 0.8 in methanol). $R_{f}: \mathrm{A}, 0.8 ; \mathrm{B}, 0 ; \mathrm{C}, 0.06$.

Cyclo(-D-Pro ${ }^{1}-$ Phe $^{2}-$ Ala $^{3}-[\boldsymbol{N}$-(2-acetamido-3,4,6-tri- $O$-acetyl-2-desoxy- $\boldsymbol{\beta}$-D-glucopyranosyl) $\mathrm{GIn}^{4}-\mathrm{Phe}^{5}-\mathrm{Ph}{ }^{6}-$ ) (XI) (MW = 1067.16). To a cooled $\left(-15^{\circ} \mathrm{C}\right)$ stirred solution of cyclo(-D-Pro ${ }^{1}-$ Phe $^{2}-$ Ala $^{3}$ Glu ${ }^{4}$-Phe ${ }^{5}-$ Phe $^{6}-$ ) ( $0.122 \mathrm{mmol}, 90 \mathrm{mg}$ ) in anhydrous THF ( 2 mL ), subsequently HOBt ( 2 equiv, $0.244 \mathrm{mmol}, 38 \mathrm{mg}$ ) and EDCI ( 2 equiv, $0.244 \mathrm{mmol}, 47 \mathrm{mg}$ ) were added. After $1 \mathrm{~h}, 2$-acetamido-3,4,6-tri- 0 -acetyl-2-desoxy- $\beta$-D-glucopyranosylamine ( 3 equiv, $0.366 \mathrm{mmol}, 127 \mathrm{mg}$ ) was added and the reaction mixture maintained for 1 h at $-15^{\circ} \mathrm{C}$ and then allowed to warm to room temperature. After 3 days, EDCI ( 2 equiv, $0.244 \mathrm{mmol}, 47 \mathrm{mg}$ ) and 2 -acetamido-3,4,6-tri- $O$-acetyl-2-desoxy- $\beta$-D-glucopyranosylamine ( 2 equiv, $0.244 \mathrm{mmol}, 85 \mathrm{mg}$ ) were added at $0^{\circ} \mathrm{C}$ for completion of the reaction. When the reaction was finished (TLC control, 5 days), the mixture was concentrated in vacuo (bath temperature below $30^{\circ} \mathrm{C}$ ), taken up in ethyl acetate, and subsequently washed with aqueous 1 N HCl , saturated $\mathrm{NaHCO}_{3}$, and saturated NaCl solution. The organic layer was dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and concentrated. Chromatography of the obtained residue with silica gel 60 ( $70-230$ mesh ASTM) in chloroform/2-propanol (10:1), evaporation of the solvent, and drying over $\mathrm{P}_{2} \mathrm{O}_{5}$ afforded the product as an amorphous white solid ( $83 \mathrm{mg}, 64 \%$ ). [ $\alpha]_{\mathrm{D}}{ }^{20}:-27.5^{\circ}$ (c 0.6 in methanol). $R_{f:}$ A, 0.76 ; B, 0.33; C, $0.09 ; \mathrm{CHCl}_{3} / 2$-propanol ( $10: 1$ ), 0.13. FAB-MS: $m / e$ $1067.5\left(\mathrm{M}+\mathrm{H}^{+}\right), 1089.5\left(\mathrm{M}+\mathrm{Na}^{+}\right) .250-\mathrm{MHz}{ }^{1} \mathrm{H}$ and $75-\mathrm{MHz}^{13} \mathrm{C}$ chemical shifts (ppm) of cyclo(-D-Pro ${ }^{1}-\mathrm{Phe}^{2}-\mathrm{Ala}{ }^{3}-[\mathrm{N}$-(2-acetamido-3,4,6-tri-O-acetyl-2-desoxy- $\beta$-D-glucopyranosyl)]Gln ${ }^{4}$-Phe ${ }^{3}$-Phe ${ }^{6}$-) in DMSO-d ${ }_{6}$ at 300 K are given in Table XI.

Cyclo(-D-Pro ${ }^{1}-\mathrm{Phe}^{2}-\mathrm{Ala}{ }^{3}-[\boldsymbol{N}$-(2-acetamido-2-deoxy- $\boldsymbol{\beta}$-D-glucopyranosyl) $\mathrm{Gln}^{4}-\mathrm{Phe}^{5}-\mathrm{Phe}^{6}$ ) (I) ( $\mathrm{MW}=941.05$ ). Cyclo(-D-Pro ${ }^{1-}$ Phe $^{2}-\mathrm{Ala}^{3}$-[ $N$-(2-acetamid-3,4,6-tri-O-acetyl-2-desoxy- $\beta$-D-glucopyranosyl)] $\mathrm{Gl}^{4}-$ Phe $^{5}-$ Phe $^{6}$ - $)(0.0328 \mathrm{mmol}, 35 \mathrm{mg})$ was coevaporated with toluene and dissolved in anhydrous methanol/ethanol ( $1: 1,1 \mathrm{~mL}$ ). After addition of KCN ( 0.6 equiv, $0.0197 \mathrm{mmol}, 1.3 \mathrm{mg}$; dried by coevaporation with toluene and applied as a solution in anhydrous methanol/ethanol ( $1: 1,1 \mathrm{~mL}$ )), the reaction was stirred in an argon atmosphere at room temperature until the reaction was completed (TLC control, 12 $h$ ). The mixture was filtered directly through a short column filled with silica gel 60 , eluted with ethanol, and concentrated. Purification by HPLC (Nucleosil C18/10 , chloroform/2-propanol (1:1)), eva poration, and drying over $\mathrm{P}_{2} \mathrm{O}$, yielded the product as an amorphous white solid ( $25 \mathrm{mg}, 81 \%$ ). $[\alpha]_{D}{ }^{20}:-24.0^{\circ}$ (c 0.9 in methanol). $R_{f}$ : chloroform/2-
propanol (1:1), 0.34.
b. NMR Measurements. All spectra were recorded on a Bruker AMX600 spectrometer, with the exception of the E.COSY (Bruker AC 250 spectrometer) and the HMBCS (Bruker AMX500 spectrometer). The samples contained 10.0 mg of I and 30.0 mg of II, respectively, in 0.5 mL of DMSO- $d_{6}$ ( $99.9 \%{ }^{2} \mathrm{H}$ atoms; Aldrich). All chemical shifts are referenced to the DMSO- $d_{6}$ signal at 2.5 ppm for ${ }^{1} \mathrm{H}$ and 39.5 ppm for ${ }^{13} \mathrm{C}$.
(1) $1 \mathrm{D}{ }^{1} \mathrm{H}$ NMR spectra: size 16 K , pulse length $3.0 \mu \mathrm{~s}, 80$ acquisitions. The spectra for determination of the temperature gradients were recorded at $300-340 \mathrm{~K}$ in steps of 10 K for I and II.
(2) DQF-COSY spectra: sequence $D_{1}-90^{\circ}-t_{1}-90^{\circ}-D_{2}-90^{\circ}-t_{2}$, relaxation delay $D_{1}=1.3 \mathrm{~s}, D_{2}=4 \mu \mathrm{~s}, 90^{\circ}$ pulse $7.8 \mu \mathrm{~s}$, spectral width in both dimensions $f_{1}$ and $f_{2} 7142.8 \mathrm{~Hz}$, quadrature detection in both dimensions.
(3) NOESY spectra: sequence $D_{1}-90^{\circ}-t_{1}-90^{\circ}-\tau_{\text {mix }}-90^{\circ}-t_{2}$, relaxation delay $D_{1}=1.3 \mathrm{~s}$, mixing time $\tau_{\text {mix }} 120 \mathrm{~ms}$, no random variation of $\tau_{\text {mix }}$, $90^{\circ}$ pulse $7.8 \mu \mathrm{~s}$, spectral width in both dimensions $f_{1}$ and $f_{2} 7142.8 \mathrm{~Hz}$, quadrature detection in both dimensions.
(4) TOCSY spectra: sequence $D_{1}-90^{\circ}-t_{1}$-MLEV17- $t_{2}$, relaxation delay $D_{1}=1.3 \mathrm{~s}$, spectra with different mixing times (duration of the spin-lock period) were recorded ( $\mathrm{a}, 20 \mathrm{~ms} ; \mathrm{b}, 80 \mathrm{~ms}$ ), $90^{\circ}$ pulse $7.8 \mu \mathrm{~s}$, spectral width in both dimensions $f_{1}$ and $f_{2} 7142.8 \mathrm{~Hz}$, quadrature detection in both dimensions.

#### Abstract

In order to provide physicochemical evidence for or against amidic resonance, three series of anilides and toluamides have been investigated by infrared spectroscopy and ${ }^{13} \mathrm{C}$ and ${ }^{15} \mathrm{~N}$ NMR, and barriers to rotation for several toluamides have been determined. Each series contains amides that are predisposed in one or more ways to disfavor resonance. These include rotation about the $\mathrm{N}-\mathrm{C}(\mathrm{O})$ bond in a series of bicyclic anilides, N -pyramidalization in a series of N -toluoyl cyclic amines, and removal of N electron density in some toluamides by inductive means or by occupying the N lone pair in an aromatic sextet. The structures of the $N$-toluoyl derivatives of azetidine, pyrrole, and 2,5 -dimethylpyrrole were determined by X-ray diffraction. The physicochemical data are generally consistent with the resonance model, but there are anomalies indicating that other factors are also important. When resonance is favored, the infrared $\nu_{\mathrm{c}}=0$ and $\nu_{\mathrm{C}-\mathrm{N}}$ bands are respectively found at lower and higher values than in amides where resonance is disfavored. The ${ }^{13} \mathrm{C}$ NMR chemical shift for a wide variety of toluamides and anilides with different resonance abilities consistently appears between $\delta 167$ and 172 ppm , except for the distorted bicyclic anilides ( $\delta 180-200 \mathrm{ppm}$ ) or $N$-toluoylaziridine ( $\delta 178 \mathrm{ppm}$ ). Since the sets include amides of considerable structural diversity, the ${ }^{13} \mathrm{C}=0$ chemical shifts are compared with the ${ }^{13} \mathrm{C}$ chemical shift of the corresponding N -methylamine: the $\Delta \delta\left({ }^{13} \mathrm{C}\right.$ )(amide-amine) values span a range of $\sim 122-143 \mathrm{ppm}$, with amides having inhibited resonance lying at the higher values. ${ }^{15} \mathrm{~N}$ chemical shifts for amides for which resonance can be invoked appear to be $\sim 80 \mathrm{ppm}$ downfield from their corresponding N -methylated tertiary amines. The ${ }^{15} \mathrm{~N}$ chemical shifts of amides in which resonance is impaired by rotation about the $\mathrm{N}-\mathrm{C}(\mathrm{O})$ bond, by N -pyramidalization, or by occupying the N lone pair in an aromatic sextet move upfield by $\sim 30-40$ ppm, but are still $45-50 \mathrm{ppm}$ downfield from their corresponding tertiary amines. The $\Delta G^{*}$ for rotation about the $\mathrm{N}-\mathrm{C}(\mathrm{O})$ bond in a series of toluamides appears to be relatively insensitive to the ability of the N to support ( + )-charge as gauged by the gas-phase basicity of the corresponding amines. Where structural and $\Delta G^{*}$ rotational data can be compared, those amides with short $\mathrm{N}-\mathrm{C}(\mathrm{O})$ bonds ( $1.34-1.37 \AA$ ) have high rotational barriers ( $14.5-16.5 \mathrm{kcal} / \mathrm{mol}$ ), while those amides with longer $\mathrm{N}-\mathrm{C}(\mathrm{O})$ bonds ( $1.40-1.42 \AA$ ) have reduced barriers to rotation ( $<6-8 \mathrm{kcal} / \mathrm{mol}$ ).

Resonance theory ${ }^{1}$ has enjoyed applicability in explaining various properties of amides such as the short $\mathrm{N}-\mathrm{C}(\mathrm{O})$ bond length, ${ }^{2}$ planar geometry, ${ }^{2}$ barrier to $\mathrm{N}-\mathrm{C}(\mathrm{O})$ rotation, ${ }^{3} \mathrm{C}=\mathrm{O}$ IR stretching frequencies, ${ }^{4}{ }^{15} \mathrm{~N}$ NMR chemical shifts, ${ }^{5}$ and kinetic stability toward nucleophilic attack/hydrolysis. ${ }^{6}$ However, the importance of resonance contributor 1a has been questioned by

2b

Wiberg and Laidig ${ }^{7}$ who have reported high-level ab initio calculations on planar and orthogonal formamides ( $1,2, R=H$, respectively) along with Bader's electron population analysis ${ }^{8}$ for the various atoms in each conformer. In contrast to what is expected on the basis of the resonance model, the computed electron population at N in $1, \mathrm{R}=\mathrm{H}$, is larger than in $2, \mathrm{R}=$ H , while the population at each O is similar. In $\mathbf{1}$, the electron population at $\mathbf{C}$ is less than in 2 so that there is a net transfer of electrons from $\mathbf{C}$ to N in the former. The $\mathrm{N}-\mathrm{C}(\mathrm{O})$ bond lengthens in passing from 1 to 2 , but the $\mathrm{C}=\mathrm{O}$ bond length is

[^12]scarcely affected. Finally, the computed barrier to $\mathrm{N}-\mathrm{C}(\mathrm{O})$ rotation ( $\mathbf{1} \boldsymbol{\mathbf { 2 b }} \boldsymbol{\mathbf { l }} \mathbf{1}$ ) is similar to the experimental one of 18-19 $\mathrm{kcal} / \mathrm{mol} .^{9}$ Wiberg and Laidig, ${ }^{7}$ Bader et al. ${ }^{10 \mathrm{a}}$ and Wiberg and

[^7]:    ${ }^{\text {a }}$ For the notation of the different MD trajectories, please see text. The distance data given in parentheses are values obtained from a $600-\mathrm{MHz}$ ROESY spectrum; they are also included in the distance constraints data file. ${ }^{\text {b }}$ Increased by 100 pm for MD run ( $\mathrm{CH}_{3}$ group (ref 42 b )). ${ }^{\text {c Increased }}$ by 90 pm for MD run ( $\mathrm{CH}_{2}$ without diastereotopic assignment (ref 42 b ). ${ }^{4}$ NOE's omitted in the MD run MD1 ${ }^{\text {b }}$ (see text).
    the coordinates of the determined averaged solution structure of I with the exception of the saccharide moiety was used. The starting structure was built according to the NMR-derived hydrogen bond patterns in both cases; some NMR derived distances have also been included in this manual model-building procedure. All peptide bonds were assumed to be in the trans configuration ( $\omega=180^{\circ}$ ), because there was no experimental indication ( ${ }^{13} \mathrm{C}$ chemical shift of D-Pro-C $\beta_{\beta}$, D-Pro-C ${ }_{\gamma}$ resonances, NOE data) for a cis orientation. ${ }^{12 n .30 c .43 .44,45}$ The side chains for I and II were
