# Skipped Cyclic Ene- and Dienediynes. 2. Models for the Homoconjugation between Double and Triple Bonds ${ }^{\dagger}$ 

Rolf Gleiter,* Roland Merger, and Hermann Irngartinger<br>Contribution from the Organisch-Chemisches Institut der Universität Heidelberg, Im Neuenheimer Feld 270, D-6900 Heidelberg, Germany. Received April 20, 1992

#### Abstract

The molecular structures of the skipped dienediynes 4,9-dimethylene-1,6-cyclodecadiyne (1) and (Z,Z)-4,10-cyclododecadiene-1,7-diyne (2) have been determined by X-ray analysis. These studies reveal a chair conformation for both compounds. The intramolecular distances between the triple bonds are 3.003 (9) $\AA$ for 1 and 3.363 (10) $\AA$ for 2 . The distances between the termini of the double and triple bonds amount to 2.490 (12) $\AA$ for 1 and 2.469 (8) $\AA$ for 2 . The PE spectra of 1 and 2 together with 12 congeners have been recorded. The assignment of the first 5-6 PE bands is based on the comparison of the PE spectra of related species as well as on MO calculations. These investigations provide clear-cut evidence for homoconjugation between double and triple bonds.

## Introduction

Since the original proposal of Winstein, ${ }^{1}$ homoconjugation between double bonds has been investigated frequently by means of different methods. ${ }^{2}$ Systematic investigations dealing with the concept of homoconjugation between triple bonds ${ }^{3}$ or even between double and triple bonds are rare or nonexistent, mainly because sufficiently simple yet conformationally rigid model systems have not been available. From the results of work on the electronic properties of cyclic dialkynes (type I), ${ }^{4,5}$ it became obvious that we would obtain ideal model compounds for the study of homoconjugation between other $\pi$-systems and triple bonds if we were able to replace the central carbon atom of one or two $\left(\mathrm{CH}_{2}\right)_{3}$ bridges in a cyclic dialkyne with such a $\pi$-system, thus generating cyclic diynes of types II and III.

By interaction of the triple bonds in cyclic dialkynes (type I) four $\pi$-MOs are formed, the energetical sequence of which depends both on the transannular distance between the alkyne units as well as on the symmetry of the highest $\sigma$-orbital of the $\left(\mathrm{CH}_{2}\right)_{n}$ bridges. ${ }^{4,5}$ Two of these $\pi$-orbitals are symmetrical, and the other two are antisymmetrical with respect to the vertical plane of symmetry ( $\sigma_{v}$ ) between the alkyne units (see below). If the additional $\pi$-systems in the bridges of type II and type III mol-

[^0]ecules are symmetrical with respect to $\sigma_{v}$, as is the case for both endo- and exocyclic $\mathrm{C}=\mathrm{C}$ double bonds, homoconjugative orbital interaction is only possible with the symmetrical and not with the antisymmetrical set of triple bond orbital combinations. Thus, the energy differences between correlated MOs in cyclic dialkynes (type I) and in "skipped" enediynes (type II) or dienediynes (type III) (in which double and triple bonds are always separated from each other by one saturated carbon atom ${ }^{6}$ ) should yield information on homoconjugative interactions between double bonds and triple bonds. Also, this comparison should provide experimental evidence for the proposed electronic structure of cyclic dialkynes, which hitherto has mainly been based on the assignment of ionization energies according to MO calculations.

[^1]We have recently synthesized ${ }^{7}$ a series of 10 skipped cyclic enediynes and dienediynes. The dienediynes are the following: 4,9-dimethylene-1,6-cyclodecadiyne (1), ( $Z, Z$ )-4,10-cyclo-dodecadiene-1,7-diyne (2), 10 -methylene-( $Z$ )-4-cycloundecene-1,7-diyne (3), and 4,9-diisopropylidene-1,6-cyclodecadiyne (4).

The cyclic enediynes are 4 -methylene-1,6-cyclodecadiyne (5), 4-methylene-1,6-cycloundecadiyne (6), ( $Z$ )-4-cycloundecene-1,7-diyne (7), ( $Z$ )-4-cyclododecene-1,7-diyne (8), 4 -iso-propylidene-1,6-cyclodecadiyne (9), and 4-isopropylidene-1,6cycloundecadiyne (10). According to perturbation theory, ${ }^{8}$ the

energy shift which is due to homoconjugative interactions strongly depends on the basis orbital energies of the interacting systems. In order to estimate these energies and for comparison, we also needed the acyclic skipped enediynes 4 -methylene- and 4 -iso-propylidene-1,6-heptadiyne ( $11^{9}$ and $12^{7}$ ) as well as ( $E$ )- and ( $Z$ )-4-octene-1,7-diyne ( 13 and 14$)^{10-12}$ and the cyclic diynes 1,6-cyclodecadiyne (15), 1,6-cycloundecadiyne (16), and 1,7 cyclododecadiyne (17).4,5

The isopropylidene-substituted diynes 4,9 , and 10 are serving as counterproofs for the expected homoconjugation effects in the other cyclic systems, since the orbital energy of the double bonds in these systems should be too high for a sizeable homoconjugative interaction with the symmetrical triple bond orbital combinations mentioned above. We therefore expected the ionization energies of the symmetrical triple bond orbital combinations of 4,9, and 10 to have nearly the same values as in the parent systems 15 and 16. The method of choice to investigate the interactions prevailing in $\mathbf{1 - 1 0}$ is $\mathrm{He}(\mathrm{I})$ photoelectron (PE) spectroscopy. The structural parameters of the enynes are important for the discussion of their electronic properties; therefore, we have investigated the structure of the key compounds $\mathbf{1}$ and 2 by the X-ray technique. In the following sections we will report on these investigations.

## Structures

(a) Structures of 1 and 2. To compare the structural parameters of 1 and 2 with their congeners $15^{4}$ and $17,{ }^{4}$ we carried out X-ray investigations on single crystals of 1 and 2 . Both molecules crystallize in a chair conformation as presented in Figure 1. In this figure we have listed the most relevant distances and angles of both molecules. ${ }^{13}$ At the endocyclic $\mathrm{sp}^{2}$ centers of 1 we note

(13) For both $\mathbf{1}$ and 2, there are two independent molecules situated on two different crystallographic centers of symmetry in the unit cell. The numbers given in Figure 1 and in the discussion are averaged values of chemically equivalent distances and angles. The scatter is given in brackets. The standard deviations of the individual values, which can be found in the supplementary material. are $0.001-0.002 \AA$ and $0.1-0.2^{\circ}$.

Figure 1. Geometry of 1 and 2 as determined by an X-ray investigation. The most relevant bond lengths ( $\AA$ ) and bond angles (deg), averaged for chemically equivalent values for both independent molecules, are given. The scatter is put in parentheses. The standard deviations are $0.001-0.002 \AA$ and $0.1-0.2^{\circ}$, respectively. ${ }^{13}$

a reduction of the bond angle within the ring (117.9(5) ${ }^{\circ}$ ) from the usual values. The triple bonds are bent ( $\left.172.0(7)^{\circ}\right)$. Both triple bonds are arranged parallel to each other, with a transannular distance of 3.003 (9) $\AA$. At the $\mathrm{sp}^{2}$ centers of 2 we note an enlargement of the bond angle within the ring (125.4 (6) ${ }^{\circ}$ ). The triple bonds are slightly less bent ( $174.1(7)^{\circ}$ ) than in 1 , and the transannular distance between the parallel triple bonds is 3.363 (10) $\AA$. The reduction of the angle at the $\mathrm{sp}^{2}$ center in 1 we ascribe to the repulsion between the exomethylene groups and the ring atoms. The enlargement of the $\mathrm{sp}^{2}$ angles in 2 reduces the transannular repulsion between the triple bonds.
A comparison of the molecular parameters of $\mathbf{1}$ and $15^{4}$ shows great similarity, which can be traced back to the mentioned reduction in the angle at the ring $\mathrm{sp}^{2}$ center in 1 to $117.9^{\circ}$ and an enlargement of the angle at centers 4 and 9 in $15\left(115.9^{\circ}\right)$. The comparison of the molecular parameters of 2 and 17 shows considerable differences in the crystal. For 2 we have found a chair conformation with parallel triple bonds. In the case of 17 a twisted chair-chair conformation was found in which the triple bonds were inclined by $24^{\circ}$, and the distance between them was found to be $4.06 \AA$, considerably longer than in 2.
The distance between the endocyclic sp ${ }^{2}$ center and the adjacent sp center in 1 amounts to 2.490 (12) $\AA$. In the case of 2 the distance between the termini of the double bond and the adjacent

triple bond is found to be 2.469 (8) A. These values are similar to the distances between the termini of the double bonds found in $1,4,7$-cyclononatriene ( $2.46 \AA$ ), ${ }^{14}$ a homoconjugated olefin. The crystallographic data of $\mathbf{1}$ and $\mathbf{2}$ and the atomic coordinates are listed in Tables I and II.
(b) Structures of 3-10. Since no single crystals of 3-10 were available, we carried out force field calculations (MMX) on these molecules to derive the molecular parameters. We chose this method because the calculated parameters for $\mathbf{1}$ and $\mathbf{2}$ compare quite well with the X-ray data. It should be mentioned that the MINDO/ 3 method also gave very satisfactory results. In Table III we have collected the most relevant data for 3-10. In Figure 2 the conformations of $\mathbf{1 - 1 0}$ are shown. As anticipated, in the 10 -membered rings smaller distances ( $3.0 \AA$ ) between the triple bonds are found than in the larger rings (3.1-4.1 $\AA$ ). With the exception of 6 and 8 , the triple bonds are predicted to be oriented almost parallel to each other. In the case of 6 the angle of inclination is predicted to be $12^{\circ}$ and in 8 to be $15^{\circ}$. The distance between the nearest termini of the endo double bond and the triple

bond is found to be $2.4 \AA$ in all cases; for the exo double bond this value is calculated to be $2.5 \AA$. The angles at the triple bonds vary between $170^{\circ}$ and $176^{\circ}$ (see Table III). The endocyclic bond angles at the $\mathrm{sp}^{2}$ atoms were found to be $120^{\circ}$ for the methylene groups, $116^{\circ}$ for the isopropylidene groups, and $125^{\circ}$ for the endocyclic double bonds, except in 7 where this angle was calculated to be $124^{\circ}$.

## Photoelectron Spectra

In interpreting the $\mathrm{He}(\mathrm{I})$ photoelectron (PE) spectra in the low-energy region, we assume that the recorded vertical ionization energies, $I_{\mathrm{y} j}$, can be directly correlated with the calculated negative values of the molecular orbital energies, $\epsilon_{j}$ (Koopmans' theorem ${ }^{15}$ ). Before presenting the PE spectroscopic results on 1-14, we will briefly discuss the results of the investigations on 15-17.4,5 The $\pi$-MOs in these species can be differentiated into a set of two $\pi_{i}$-orbitals which lie "in the molecular plane" that is defined by the two parallel triple bonds, $\pi^{1}$ and $\pi^{2}$, and a set of two $\pi_{0}$-orbitals which are perpendicular to this plane. Within both sets two linear combinations can be formed, one of which is bonding, $\pi^{+}$, and one of which is antibonding, $\pi^{-}$, with respect to the vertical plane of symmetry between the triple bonds ( $\sigma_{v}$, see the Introduction).

$$
\pi_{\mathrm{i}}^{ \pm}=1 / \sqrt{2}\left(\pi_{\mathrm{i}}^{1} \pm \pi_{\mathrm{i}}^{2}\right) \text { and } \pi_{0}^{ \pm}=1 / \sqrt{2}\left(\pi_{0}^{1} \pm \pi_{0}^{2}\right)
$$

The PE spectroscopic investigations on 15 reveal a strong interaction between $\pi_{\mathrm{i}}^{-}$and the $\sigma$-frame of the propano groups. Thus the band which is assigned to the ionization from $\pi_{i}^{-}\left(I_{v, 1}=8.47\right.$ eV ) is considerably separated (by 1.5 eV ) from the $\pi_{\mathrm{i}}{ }^{+}$-band ( 10.02 eV ). The sequence of the $\pi_{0}$-bands is less clear-cut, because semiempirical and ab initio (3-21G basis) calculations suggest ${ }^{4}$ the assignment of the second band in the PE spectrum of 15 (9.12 $\mathrm{eV})$ to be $\pi_{0}^{+}$and the third one $(9.42 \mathrm{eV})$ to be $\pi_{0}^{-}$. These results

are due to a stronger hyperconjugative interaction of $\pi_{0}{ }^{+}$with the adjacent $\mathrm{CH}_{2}$ groups as compared to $\pi_{0}{ }^{-}$(predicted by the calculations). An empirical assignment ${ }^{5}$ places $\pi_{0}{ }^{-}$at lower ionization

[^3]

Figure 3. PE spectra of $\mathbf{1 - 3}, \mathbf{5}, 7$, and 12.
energy than $\pi_{0}{ }^{+}$. For 16 the sequence of the bands parallels that of 15 ; hence, the splitting of the bands is smaller, although $\Delta I\left(\pi_{\mathrm{i}}\right)$ $=0.92 \mathrm{eV}$ and $\Delta I\left(\pi_{\mathrm{o}}\right)=0.27 \mathrm{eV}$. In 17 we observed only two close-lying peaks at 9.13 and 9.38 eV , which indicates a very small interaction between the triple bonds. To elucidate the interactions in 1-4 and their congeners 5-14, we recorded their photoelectron (PE) spectra. As examples we show the PE spectra of 1-3 together with those of 5, 7, and 12 (Figure 3). We note strongly overlapping bands for the dienediynes 2 and 3 , but more easily recognizable bands for 1 and the enediynes, especially those with a 10 - or 11 -membered-ring skeleton. To correlate the different peaks with the MOs, we compared the spectra with those which can be easily assigned empirically (11-14) or with 15-17, whose spectra have been interpreted recently. ${ }^{4,5}$ The ionization energies of 1-14 are collected in Table IV.

In addition to the empirical correlation we also rely on MO calculations. Procedurally we use ab initio calculations with a $3-21 \mathrm{G}$ basis set ${ }^{16}$ based on geometrical parameters derived from a MINDO/ $3{ }^{17}$ calculation (we used the MINDO/ 3 method because it has performed reasonably well for cyclic diacetylenes of medium ring size ${ }^{5}$ ); for $\mathbf{1}$ and $\mathbf{2}$ the experimental geometry has been used in addition to the above basis set. As there are hardly any differences in the ring geometry of the 10 -membered rings $1,4,5,9$, and 15 , their ionization energies can be correlated directly, without having to consider changes in the intramolecular distances between the interacting $\pi$-systems. We therefore start our discussion of the PE spectra with these systems.

## PE Spectra of the $\mathbf{1 0}$-Membered Rings 1, 4, 5, and 9

(a) Ionization Energies of the Double Bonds and the Out-ofPlane Orbitals. To understand the PE spectra of 1 and 4 , we start by discussing the PE spectra of simpler models such as those of $5,9,11$, and 12. In order to estimate the ionization energy of

${ }^{a}$ All values are in electronvolts.

Figure 4. Comparison of the first PE bands of 5,9,11, and 12.
the $\pi$-MO localized at the exomethylene group, we compared the PE spectra of 11 and 12 with those of 5 and 9 (Figure 4). The PE spectrum of 11 shows one peak at 9.63 eV and four strongly overlapping bands centered around 10.6 eV . A comparison with the PE spectrum of 1,1-dimethylethene ( $\left.I_{v, 1}=9.44 \mathrm{eV}\right)^{18}$ and the first bands of propyne ( $I_{v, 1}=10.36 \mathrm{eV}$ ) ${ }^{19}$ suggested the assignment of the peak at 9.6 eV to the ionization from the double bond in $11\left(\pi_{\mathrm{d}}\right)$ and the bands at 10.6 eV to the triple bonds ( $\pi_{\mathrm{t}}$ ). The suggested assignment is corroborated by comparison of the PE bands of 11 with those of 12 (Figure 4, Table IV). This comparison leads to a shift toward lower energy for the first band by 0.88 eV and for the bands at higher energy by an average value of 0.4 eV , which is anticipated from first-order perturbation theory. ${ }^{8}$

The comparison of the PE spectra of 5 and 11 (Figure 4) suggests assigning band 3 or 4 of the PE spectrum of 5 to the ionization of the $\pi$-MO at the double bond ( $\pi_{\mathrm{d}}$ ). The other four peaks are assigned to the ionization of $\pi-\mathrm{MO}$ s at the triple bonds. The latter we classify as the "in-plane" linear combinations $\pi_{i}{ }^{+}$ and $\pi_{i}^{-}$and the "out-of-plane" linear combinations $\pi_{0}^{+}$and $\pi_{0}^{-}$, as discussed in the previous paragraph for 15-17. We chose to assign the third band in the PE spectrum of 5 to the ionization from $\pi_{0}{ }^{+}$and the fourth band to $\pi_{\mathrm{d}}$ because both calculation methods predict this sequence. According to the 3-21G calculation, the energy of the $\pi_{0}{ }^{+}$orbital is only slightly affected by the introduction of the double bond(s) in 1 and 5, since the through-space interactions of these orbitals are largely compensated by hyperconjugation effects with the allylic-propargylic $\mathrm{C}-\mathrm{H}$ bonds. By following this choice the empirical band sequence for $1,4,5$, and 15 parallels the one derived from the $3-21 G$ calculations (see below). The ionization from the exomethylene double bond(s) in 1 and 5 we ascribe to the band at $9.6-9.8 \mathrm{eV}$. The comparison between the bands of 5 and 9 (Figure 4) as well as between 1 and 4 shows the anticipated low-energy shift of the $\pi_{\mathrm{d}}$-band(s) by 1.1 eV .

$$
\sigma^{\prime}\left(\pi_{0}+\pi_{d}-\sigma\right)
$$

The observation that the second band in the series 1,5 , and 15 remains at constant energy (see Figure 5) is best explained by assigning it to $\pi_{0}{ }^{-}$since, due to its nodal properties, ${ }^{8}$ this orbital should not be affected by the double bonds. This assignment is further supported by the fact that the energy of the $\pi_{0}{ }^{-}$combination also remains unchanged in 4 and 9 as well as in the larger rings (see below).
(b) Ionization Energies of the In-Plane Orbitals. In Figure 5 we have correlated the first PE bands of 15 with those of 1,4 , and 5. The slight shift of the first band in 1 and $5\left(\pi_{i}^{-}\right)$toward higher energy is understandable if we recall that in 15 the strong

[^4]

Figure 5. Comparison of the first PE bands of $1,4,5$, and 15.
split between $\pi_{i}^{-}$and $\pi_{i}^{+}$is due to an intense through-bond interaction of $\pi_{i}^{-}$with the highest $\sigma$-orbitals of the propano chains. Replacement of the sp ${ }^{3}$ center either at $C(4)$ or at both $C(4)$ and $C(9)$ in 15 by an $\mathrm{sp}^{2}$ center of the exomethylene group(s) will diminish the through-bond interaction somewhat by lowering the basis orbital energy for the corresponding $\sigma$-orbitals. In 4 and 9 this small effect is overcompensated by an increase of the energy of the propano chain orbitals caused by the methyl groups. Consequently, we find a slight shift of $\pi_{i}^{-}$toward lower ionization energy. Most interestingly, the comparison between 1 or 5 and $\mathbf{1 5}$ shows a significant shift of $\pi_{\mathrm{i}}{ }^{+}$in $\mathbf{1}(+0.33 \mathrm{eV})$ and $5(+0.21$ eV ) toward higher ionization energy (Figure 5). We consider this to be clear-cut evidence for a homoconjugative interaction between the double bond(s) and the triple bonds in 1 and 5 . The resulting linear combinations are shown schematically.

The change from 1 to 4 and from 5 to 9 resulted in the anticipated strong shift of $\pi_{d}$ toward lower energy, which indicates a large energy difference between the basis orbital energies of the double and triple bond(s) in 4 and 9 . As a consequence, in 4 and 9 the homoconjugative effects between the double bond(s) and $\pi_{i}^{+}$should be a lot weaker than in 1 and 5 . The PE spectra fully confirm this prediction, since the ionization energies assigned to the $\pi_{i}^{+}$orbitals of 4 and 9 are almost identical with the corresponding value of $15\left(\pi_{i}^{+}(15), 10.02 \mathrm{eV} ; \pi_{i}^{+}(4), 9.98 \mathrm{eV} ; \pi_{i}^{+}(9)\right.$, 10.0 eV ). This is a clear counterproof for the proposed homoconjugative interactions in 1 and 5 .

## PE Spectra of the 11- and 12-Membered Rings 2, 3, 6-8, and 10

The assignment of the PE spectra of 2,3 , and 8 is hampered by the fact that only the first and last band in the area between 8.8 and 10.2 eV can be recognized clearly. In the region in between, we find mainly strongly overlapping bands. Our assignment relies on the results of the MO calculations, qualitative considerations, and the comparison with 6,7 , and the $10-\mathrm{mem}$ bered rings.
To understand the electronic structure of the 11-membered rings qualitatively, we have compared the PE spectra of $3,6,7$, and 16 in Figure 6. The first band and the last band are assigned to $\pi_{\mathrm{i}}^{-}$and $\pi_{\mathrm{i}}^{+}$, respectively. This follows from the correlation with the first and last bands of 16 and is confirmed by the MO calculations. Again, in the case of 6 , we find a strong stabilization of $\pi_{i}^{+}$by homoconjugation with the exomethylene group, which is completely analogous to the situation in 1 and 5 . The "counterproof" works equally well as for the 10 -membered rings, as the ionization energies assigned to the $\pi_{\mathrm{i}}^{+}$combinations of $\mathbf{1 0}$ and 16 are almost identical ( $\left.\pi_{\mathrm{i}}{ }^{+}(10), 9.68 \mathrm{eV} ; \pi_{\mathrm{i}}^{+}(16), 9.69 \mathrm{eV}\right)$.

In the case of 3 and 7, there are considerable differences in the ring geometry as compared to $16 .^{5}$ Whereas in 16 the triple bonds are calculated to be inclined by $10.2^{\circ}$ (MMX), in 3 and 7 they

Figure 6. Comparison of the first PE bands of $\mathbf{3 , 6 , 7}$, and 16.
are oriented parallel and the distance between Cl and C 7 is about $0.2 \AA$ shorter than in 16. Therefore, the through-space interaction and the resulting energy split between the two in-plane combinations must be somewhat larger than in 16, a fact which can be clearly seen in a slight decrease of the ionization energy of the $\pi_{i}^{-}$combination in $\mathbf{3}$ and 7 . However, in $\mathbf{3}$ and 7 we also observe a much stronger shift of $\pi_{i}^{+}$toward higher ionization energy, which provides clear evidence for the stabilization of $\pi_{i}^{+}$by homoconjugation with the endocyclic double bond. Since the second band in $3,6,7$, and 16 remains rather constant ( 9.1 eV ), we assign it to the ionization event from $\pi_{0}{ }^{-}$. This assumption is based on the fact that $\pi_{0}^{-}$is not interacting with the double bonds for reasons of symmetry (as already discussed in connection with the PE spectrum of the 10 -membered rings), and it is supported by the fact that the energy thus assigned to $\pi_{0}^{-}$is almost identical with the corresponding values of the 10 -membered rings.

The PE spectra of 13 and 14 (Table IV) reveal that there is no significant difference in ionization energy between the endocyclic double bond in 3 and 7 and a methylene double bond as in 6. Both spectra show one band at 9.6 eV , which is assigned to the ionization from the double bond and which is well separated from a broad peak of four triple bond ionizations around 10.5 eV (Table IV). Therefore, and in analogy to the $10-$ membered rings, we assign band 3 of the PE spectra of 3,6 , and 7 to the ionization from $\pi_{0}^{+}$. Band 4, and in the case of 3 also band 5 , we assign to the ionization from the double bonds. In the case of 3 and 7, this assignment differs from the results of the calculations (Table II). From a comparison of the experimental values with the results of the calculations for 11, 13, and 14, we conclude that the calculations tend to underestimate the ionization energy of the internal double bonds; for this reason we support the empirical assignment.

As in the case of 3 and 7, there are differences in the ring geometry between 2 and 8 and their parent system 17. ${ }^{4}$ The distances between the acetylenic carbon atoms in 8 (4.1 and 3.8 $\AA$ ) are somewhat shorter than the distances in 17 (4.06 $\AA$ ); however, they are still considerably longer than the van der Waals distance $(3.4 \AA)^{20}$ and the triple bonds remain skewed. Thus we do not expect significant differences in the through-space interactions of the triple bonds between 8 and 17. In changing from 17 to 8, the energy of $\pi_{\mathrm{i}}^{-}$should therefore remain constant, but in $8 \pi_{i}^{+}$should be considerably stabilized by homoconjugation with the endocyclic double bond. As in 2 the triple bonds are parallel and the distance between them ( $3.36 \AA$ ) is close to the van der Waals value; a slight shift of $\pi_{\mathrm{i}}^{-}$toward lower ionization energy can be anticipated, but the stabilization of $\pi_{i}{ }^{+}$by homoconjugation should still be the dominating effect in causing a stronger split between the in-plane orbitals compared to 17. In Figure 7 we have correlated the PE bands of 2, 8, and 17. As

[^5]

Figure 7. Comparison of the first PE bands of 2, 8, and 17.
we find strongly overlapping bands in the PE spectra of 2 and 8 , it is impossible to assign individual ionization energies to all MOs. However, the predictions discussed above are fully confirmed. According to the 3-21G calculation, we assign the highest ionization energies of $8(9.1 \mathrm{eV})$ and $17(9.13 \mathrm{eV})$ to the $\pi_{0}{ }^{-}$orbital. As expected, these values are almost identical with the corresponding energies of the 11 - and 10 -membered rings. According to the $3-21 \mathrm{G}$ calculations, the broad peak at 9.3 eV in the PE spectrum of 8 is assigned to the ionizations from $\pi_{0}^{-}, \pi_{0}^{+}$, and $\pi_{\mathrm{d}}$, and the first ionization peak of $2(9.0-9.5 \mathrm{eV})$ is assigned to the ionizations from $\pi_{\mathrm{i}}^{-}, \pi_{0}^{-}, \pi_{0}^{+}$, and the two $\pi_{\mathrm{d}}$ combinations. The strong overlap of the first five ionizations in the PE spectrum of $\mathbf{2}$ is not surprising as the $3-21 G$ method predicts the four highest MOs of 2 to have almost identical energy. From the first ionization bands of $\mathbf{2}$ and $\mathbf{8}$ we learn that in fact there is no considerable destabilization of $\pi_{\mathrm{i}}^{-}$in these two molecules as compared to 17. This confirms our prediction that the geometrical differences between 2, 8, and 17 do not cause a significant change in the through-space interactions of the triple bonds within this series. The peak at 9.88 eV in the PE spectrum of 8 and at 10.0 eV in that of 2 we assign to linear combinations which result from the interaction between $\pi_{i}^{+}$and the double bond(s). As the geometrical differences are not important, the strong shift of the ionization assigned to $\pi_{i}^{+}$in 8 and 2 (Figure 7) can be attributed to homoconjugation between the double and the triple bonds. The resulting linear combinations are shown schematically.

## Conclusions

The X-ray investigations on $\mathbf{1}$ and $\mathbf{2}$ show that the structural requirements for homoconjugative interactions between the double bonds and triple bonds are met. The distances between the termini of the double and triple bonds are as close as in the corresponding olefinic models. The PE spectroscopic investigations on 1-10 reveal a sizeable homoconjugation between the double and triple bonds. It is evidenced by a high-energy shift of bands by about 0.2 eV per double bond. To our knowledge this is the first time that such an interaction has been shown. The PE investigations furthermore reveal a confirmation of the assignment of the second band in the PE spectra of $\mathbf{1 5}$ and 16 to $\pi_{0}^{-}$. This assignment is in contrast to the prediction of calculations.

Acknowledgment. We thank the Deutsche Forschungsgemeinschaft (SFB 247), the Volkswagen-Stiftung, the State of Baden-Württemberg, the Fonds der Chemischen Industrie, and the BASF Aktiengesellschaft, Ludwigshafen, for financial support. R.M. is grateful to the Studienstiftung des Deutschen Volkes for a graduate fellowship. We thank N. Jochum for typing the manuscript.

Supplementary Material Available: Tables of atomic coordinates of the hydrogen atoms, anisotropic displacement factors of the carbon atoms, bond lengths, bond angles, and selected interatomic distances of 1 and 2 ( 3 pages). Ordering information is given on any current masthead page.
