Received January 22, 1993

Permethylyttrocene alkyl and hydrido derivatives $\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}-\mathrm{R}$ ( $\mathrm{Cp}^{*}=\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{5} ; \mathrm{R}=\mathrm{H}, \mathrm{CH}\left(\mathrm{SiMe}_{3}\right)_{2}$ ) are effective catalysts for a variety of reactions. ${ }^{1}$ Previously we have found that $\mathrm{Cp}^{*}{ }_{2}{ }^{-}$ $\mathrm{LnR}\left(\mathrm{Ln}=\mathrm{Y}, \mathrm{La}, \mathrm{Ce} ; \mathrm{R}=\mathrm{CH}\left(\mathrm{SiMe}_{3}\right)_{2}\right)$ catalyzes, for instance, the oligomerization of terminal alkynes. ${ }^{1 \mathrm{a}, 2}$ We were interested in exploring yttrium-based systems with an alternative coordination environment and comparing these with the known chemistry. We have chosen the bidentate $N, N^{\prime}$-bis(trimethylsilyl)benzamidinate ligand, earlier employed by Roesky, ${ }^{3}$ Dehnicke ${ }^{4}$ and Edelmann, ${ }^{\text {S }}$ to develop new catalytic group 3 chemistry for $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bond formation.

Here we describe the preparation of bis( $N, N^{\prime}$-bis(trimethylsilyl) benzamidinate) yttrium hydride, $\left\{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{NSiMe}_{3}\right)_{2}\right]_{2} \mathrm{Y}-\mu\right.$ $\mathrm{H}\}_{2}$, and its use as a precursor in the catalytic dimerization of terminal alkynes, together with the synthesis and crystal structure of the novel acetylide complex $\left\{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{NSiMe}_{3}\right)_{2}\right]_{2} \mathrm{Y}-\mu\right.$ $\mathrm{C}=\mathrm{CH}\}_{2}$.

Multigram quantities of the chloride complex $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\right.$ ( $\left.\mathrm{NSiMe}_{3}\right)_{2} \mathrm{l}_{2} \mathrm{YCl} \cdot \mathrm{THF}(1)^{7 a}$ can be easily obtained by reaction of $\mathrm{Li}\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{NSiMe}_{3}\right)_{2}\right]^{6}$ with $\mathrm{YCl}_{3} \cdot \mathrm{THF}_{3.5}{ }^{7 \mathrm{~b}}$ The chloride is an excellent precursor to new yttrium alkyl complexes. ${ }^{8}$ For instance, reaction of 1 with $\mathrm{LiCH}\left(\mathrm{SiMe}_{3}\right)_{2}$ afforded salt-free $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{NSiMe}_{3}\right)_{2}\right]_{2} \mathrm{YCH}\left(\mathrm{SiMe}_{3}\right)_{2}$ (2). ${ }^{7 \mathrm{~b}}$ The proton-coupled ${ }^{13} \mathrm{C}$ NMR spectrum of 2 shows a double doublet from the methyne carbon at $\delta 43.5$ ( ${ }^{1} J_{Y-C}=30 \mathrm{~Hz},{ }^{1} J_{C-H}=88 \mathrm{~Hz}$ ), which is shifted significantly downfield from the $\mathrm{C}-\mathrm{H}$ resonance in $\mathrm{Cp}^{*}{ }_{2} \mathrm{YCH}-$ $\left(\mathrm{SiMe}_{3}\right)_{2}$ ( $\delta 25.2$ ), ${ }^{9}$ suggesting a more electrophilic yttrium environment in 2. Like in $\mathrm{Cp}^{*}{ }_{2} \mathrm{YCH}\left(\mathrm{SiMe}_{3}\right)_{2}\left({ }^{1} J_{\mathrm{C}-\mathrm{H}}=84 \mathrm{~Hz}\right)$, ${ }^{9}$ the small coupling constant for the $\alpha$-carbon resonance ( ${ }^{1} J_{C-H}=$ 88 Hz ) indicates an agostic interaction ${ }^{10}$ of the alkyl C-H bond with yttrium as is expected for an electronically very unsaturated

[^0]compound ( 14 electron system at maximum). Treatment of 2 with dihydrogen ( $3 \mathrm{~atm}, 40^{\circ} \mathrm{C}$ ) in benzene gives the very airsensitive hydride $\left\{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{NSiMe}_{3}\right)_{2}\right]_{2} \mathrm{Y}-\mu-\mathrm{H}\right\}_{2}(3){ }^{76}$ The ${ }^{1} \mathrm{H}$ NMR spectrum of 3 shows a triplet at $8.3 \mathrm{ppm}\left({ }^{1} J_{Y-H}=27.6\right.$ Hz ), which suggests a symmetric dimeric structure in solution. ${ }^{11}$ None of the synthesized complexes (1-3) shows any disproportionation or decomposition after 24 h at $100^{\circ} \mathrm{C}$ in benzene, demonstrating the high stability of this new class of yttrium compounds.
With 3 available, we were interested in examining the reactivity with terminal alkynes, and making comparisons with the bis(permethylcylopentadienyl) analogues of yttrium, lanthanum, and cerium. Treatment of 3 with an excess of $H C \equiv C R(R=$ $t-\mathrm{Bu}, \mathrm{Ph}$ ) gives a slow but selective reaction affording the head-to-tail coupled product $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}(\mathrm{R}) \mathrm{C} \equiv \mathrm{CR}(\mathrm{R}=t$ - $\mathrm{Bu}, \mathrm{Ph}) .{ }^{12}$ However, for $\mathrm{HC} \equiv \mathrm{CSiMe}_{3}$, a dramatic change in regioselectivity takes place and catalytic dimerization to exclusively the head-to-head coupled product trans- $\mathrm{R}(\mathrm{H}) \mathrm{C}=\mathrm{C}(\mathrm{H}) \mathrm{C} \equiv \mathrm{CR}$ ( $\mathrm{R}=$ $\mathrm{SiMe}_{3}$ ) is observed. ${ }^{12,13}$ By contrast, the $\mathrm{Cp}^{*}{ }_{2} \mathrm{LnR}$-catalyzed coupling of $\mathrm{HC} \equiv \mathrm{CPh}$ and $\mathrm{HC} \equiv \mathrm{CSiMe}_{3}$ gives either mixtures of head-to-tail and head-to-head isomers ( $\mathrm{Ln}=\mathrm{Y}$ ) or formation of higher oligomers $(\mathrm{Ln}=\mathrm{La}, \mathrm{Ce}) .{ }^{2}$ The mechanism for this reaction is believed to be the same as for the catalytic dimerization of terminal alkynes by $\mathrm{Cp}^{*}{ }_{2} \mathrm{LnR}(\mathrm{Ln}=\mathrm{Sc}, \mathrm{Y}, \mathrm{La}, \mathrm{Ce})$. ${ }^{\mathrm{la}, 2,14}$ Unlike $\mathrm{Cp}^{*}{ }_{2} \mathrm{ScMe},{ }^{15} 3$ does not oligomerize ethyne. Treating 3 with an excess of ethyne resulted in the formation of an acetylide. ${ }^{7 \mathrm{~b}}$ An X-ray structure determination revealed the compound to be $\left\{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{NSiMe}_{3}\right)_{2}\right]_{2} \mathrm{Y}-\mu-\mathrm{C} \equiv \mathrm{CH}\right\}_{2}$ (4), a dimer with bridging ethynyl groups. 4 was also prepared by treatment of 2 with ethyne in benzene (eq 1). ${ }^{7 \mathrm{~b}}$

An ORTEP drawing of $\mathbf{4}$ is shown in Figure 1. The unit cell contains two crystallographically independent moiecules, both obeying $C_{2}$ symmetry, that do not differ mariediy in their structures. ${ }^{16}$ In one molecule, two identical $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}(\mathrm{N}\right.$ $\left.\left.\mathrm{SiMe}_{3}\right)_{2}\right]_{2} \mathrm{Y}-\mathrm{C} \equiv \mathrm{CH}$ units are related to each other by a 2 -fold axis perpendicular to the plane of the acetylide bridge. In the other molecule, the two yttrium atoms are on a special pusition along the 2 -fold axis, with disordered acetylide fragments. Notable features of the nondisordered molecule will be discussed

[^1]

Figure 1. ORTEP drawing of $\left\{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\left(\mathrm{NSiMe}_{3}\right)_{2}\right]_{2} \mathrm{Y}-\mu-\mathrm{C} \equiv \mathrm{CH}\right\}_{2}$ (4). Only one of the crystallographically independent molecules is shown with $50 \%$ probability ellipsoids.
here (Figure 1). 4 is formed by two distorted octahedral yttrium atoms, each coordinated by two chelating benzamidinate ligands and two bridging acetylides. Due to a trans-effect, the $Y(3)$ $\mathrm{N}(5)(2.395(4) \AA)$ and $\mathrm{Y}(3)-\mathrm{N}(8)(2.381(4) \AA)$ bond lengths are longer than $\mathrm{Y}(3)-\mathrm{N}(6)(2.345(4) \AA)$ and $\mathrm{Y}(3)-\mathrm{N}(7)(2.335(4)$ $\AA$ ) (trans to the acetylide). The $\mathrm{Y}(3)-\mathrm{C}(29)(2.556(5) \AA)$ and $\mathrm{Y}(3) \mathrm{a}-\mathrm{C}(29)(2.509(5) \AA)$ bonds are longer than in $\mathrm{Cp}^{*}{ }_{2} \mathrm{Y}(\mu-$ $\left.\mathrm{C} \equiv \mathrm{CCMe}_{3}\right)_{2} \mathrm{Li} \cdot \mathrm{THF}(2.38(2) \AA)^{17 \mathrm{a}}$ but very similar to the Y-C distances in $\left[\mathrm{Cp}_{2} \mathrm{Y}-\mu-\mathrm{Me}\right]_{2}$ (2.553(1), 2.537(9) $\AA$ ). ${ }^{17 \mathrm{~b}}$ The Y-C bond lengths of 4 compare well with the $\mathrm{Ln}-\mathrm{C}$ distances of some 4f element acetylide complexes, $\left[\mathrm{Cp}^{\prime}{ }_{2} \mathrm{Ln}-\mu-\mathrm{C} \equiv \mathrm{CR}\right]_{2}\left(\mathrm{Cp}^{\prime}=\right.$ substituted cyclopentadienyl, $\mathrm{Ln}=\mathrm{Sm}, \mathrm{Er}$ ) when the differences

[^2]in atomic radii are taken into account. ${ }^{18}$ A remarkable feature is that, in contrast to the $\mathrm{Cp}^{*}{ }_{2} \mathrm{Ln}$ ( $\mathrm{Ln}=\mathrm{La}, \mathrm{Ce},{ }^{19 \mathrm{a}}$ and $\mathrm{Sm}^{196}$ ) systems, no coupling of acetylide fragments is observed. Both the $\mathrm{Y}(3)-\mathrm{C}(29)$ and $\mathrm{Y}(3) \mathrm{a}-\mathrm{C}(29)$ bond lengths and the $\mathrm{Y}(3)$ -$\mathrm{C}(29)-\mathrm{C}(30)$ (98.4(5) ${ }^{\circ}$ ) and $\mathrm{Y}(3) \mathrm{a}-\mathrm{C}(29)-\mathrm{C}(30)\left(159.8(5)^{\circ}\right)$ angles indicate that the bridge is clearly asymmetric with a strong interaction of the $\alpha$-carbon atom, $\mathrm{C}(29)$, with both yttrium centers. The acetylide absorption ( $\nu(\mathrm{C} \equiv \mathrm{C}) 1915 \mathrm{~cm}^{-1}$ ) in the IR spectrum (cf. $\left.\nu(\mathrm{C} \equiv \mathrm{C})\left(\mathrm{Cp}_{3} \mathrm{UC} \equiv \mathrm{CH}\right) 2062 \mathrm{~cm}^{-1}\right),{ }^{20}$ the ${ }^{1} J_{C-H}$ coupling constant for $\mathrm{YC} \equiv \mathrm{CH}$ of 218 Hz in the ${ }^{13} \mathrm{C}$ NMR spectrum, and the $\mathrm{Y}(3) \mathrm{a}-\mathrm{C}(29)-\mathrm{C}(30)$ angle of $159.8(5)^{\circ}$ suggest $\eta^{2}$ interaction of the triple-bond $\pi$ orbitals with $Y(3) .{ }^{18 a}$ Since $\pi$ interaction of the acetylide is expected to result in elongation of the $\mathrm{C} \equiv \mathrm{C}$ bond, the $\mathrm{C}(29)-\mathrm{C}(30)$ bond length of $1.164(8) \AA$, shorter than that in free acetylene ( $1.21 \AA$ ), is very surprising.
These preliminary results show that the $N, N^{\prime}$-bis(trimethylsilyl)benzamidinate acts as an inert spectator ligand in these complexes. The thermal stability and catalytic activity of 3 clearly demonstrate that a much more diverse chemistry is available to yttrium than that of cyclopentadienyl systems only. Indeed, exploratory experiments showed that the hydride $\left\{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{C}\right.\right.$ $\left.\left.\left(\mathrm{NSiMe}_{3}\right)_{2}\right]_{2} \mathrm{Y}-\mu-\mathrm{H}\right\}_{2}$ (3) also polymerizes ethene under mild conditions. These promising perspectives for catalytic C-H and $\mathrm{C}-\mathrm{C}$ bond formation are currently under investigation.

    (12) The reactions were followed by 'H NMR at elevated temperatures ( $70-100^{\circ} \mathrm{C}$, average turnover number of $35 \mathrm{~h}^{-1}$ ), and the products were characterized by GC/MS and 'H NMR ( $\mathrm{R}=t$-Bu, GC pure; $\mathrm{R}=\mathrm{Ph},>95 \%$; $\mathrm{R}=\mathrm{SiMe}_{3}, \mathrm{GC}$ pure).
    (13) Stockis and Hoffman have performed calculations on the polarization of the $\pi^{*}$ orbitals in (trimethylsilyi)acetylene and propyne. The alkyne substituent has a pronounced influence on the electron density of the alkyne sp-carbon atoms, and distinct differences in polarization were found for both alkynes. These electronic effects are believed to be responsible for the difference in regioselectivities of the dimerization reactions. Stockis, A.; Hoffman, R. J. Am. Chem. Soc. 1980, 102, 2952-2962.
