Mixed-metal clusters ${ }^{1,2}$ often exhibit unusual structures and properties and cooperative (synergistic) effects which are important in the development of such critical technologies as catalysis ${ }^{3}$ and nanoelectronics. ${ }^{4}$ We report herein the synthesis and structure of the largest trimetallic $(\mathrm{Au} / \mathrm{Ag} / \mathrm{Pt})$ cluster known to date.

Our recent work on bimetallic $\mathrm{Au}-\mathrm{Ag}$ clusters has yielded a novel series of clusters whose metal frameworks are based on vertex-sharing polyicosahedra. ${ }^{5-10}$ We refer to these highnuclearity mixed-metal clusters as "clusters of clusters". This cluster of clusters series follows well-defined design rules, giving rise to a novel growth sequence by successive additions of icosahedral units via vertex-sharing, as exemplified by the biicosahedral ${ }^{8}\left[\left(p \text {-tol }{ }_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{13} \mathrm{Ag}_{12} \mathrm{Br}_{8}\right]^{+,}{ }^{86}$ the triicosahedral ${ }^{9}$ $\left[\left(p \text {-tol }{ }_{3} \mathrm{P}\right)_{12} \mathrm{Au}_{18} \mathrm{Ag}_{20} \mathrm{Cl}_{14}\right],{ }^{9,9}$ and the tetraicosahedral ${ }^{10}\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{12^{-}}\right.$ $\mathrm{Au}_{22} \mathrm{Ag}_{24} \mathrm{Cl}_{10}$ ] clusters. The biicosahedral 25 -metal-atom cluster (mac) series ${ }^{8}$ of general formulas $\left[\left(\mathrm{R}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{13} \mathrm{Ag}_{12} \mathrm{X}_{8}\right]^{+}$and $\left[\left(\mathrm{R}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{13} \mathrm{Ag}_{12} \mathrm{X}_{7}\right]^{2+}$ (where $\mathrm{R}=$ phenyl or tolyl; $\mathrm{X}=\mathrm{Cl}$ or $\mathrm{Br})$ is particularly interesting in that these compounds exhibit various metal configurations and bridging ligand arrangements due to relative rotations of the two metal icosahedra (about the shared vertex) and the satellite ring of bridging ligands, respectively (represented by large circles and an ellipse, respectively, in Chart I, top figures). For example, the monocationic cluster $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{13} \mathrm{Ag}_{12} \mathrm{Br}_{8}\right]^{+8 \mathrm{c}}$ (1b), with a staggered-eclipsed-staggered (ses) arrangement of four adjacent metal pentagons, has a ring of six bromides bridging the two middle silver pentagons, while the dicationic clusters $\left[\left(p-\text { tol }_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{13} \mathrm{Ag}_{12} \mathrm{Cl}_{7}\right]^{2+8 \mathrm{ec}}(\mathbf{2})$, with a nearly ses metal configuration, has five bridging halides.

## Chart I

(

The title cluster, $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{PtCl}_{7}\right] \mathrm{Cl}$ (3), which represents the first example of a trimetallic polyicosahedral supracluster, was synthesized by reducing a mixture of $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{8} \mathrm{Au}_{8}-\right.$ $\mathrm{Pt}]\left(\mathrm{NO}_{3}\right)_{2}{ }^{11}(0.07 \mathrm{mmol})$ and $\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{4} \mathrm{Ag}_{4} \mathrm{Cl}_{4}{ }^{12}(0.1 \mathrm{mmol})$ with $\mathrm{NaBH}_{4}(0.3 \mathrm{mmol})$ in ethanol. The resulting dark red precipitate was filtered and recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{CH}_{3} \mathrm{CN}$. Preparative and spectroscopic details are given in the supplementary material. Figures $1 a$ and $b$ depict the $\left[\mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{Pt}\right]$ core and [ $\mathrm{P}_{10} \mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{PtCl}_{7}$ ] framework of 3 , respectively. ${ }^{13}$ Under space group $P 2_{1} / m$, the cluster resides on the crystallographic $C_{s}-\mathrm{m}$ site symmetry (passing through Au 13 and $\mathrm{Cl} 1-\mathrm{Cl} 5$ ). The metal core can be described as two $\mathrm{Au}_{6} \mathrm{Ag}_{6}$ icosahedra, one Pt-centered and one Au-centered (designated as AP11 and AP11' due to the mirror-related disorder), sharing a common gold (Au13) atom. ${ }^{14}$ The four metal pentagons adopts the ses configuration. The 10

(13) Single crystal X-ray diffraction data were collected using an EnrafNonius diffractometer (Mo radiation). $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{PtCl}_{7}\right](\mathrm{Cl})$ : monoclinic $P 2_{1} / m, a=16.534(4) \AA, b=24.360(5) \AA, c=29.819(5) \AA, \beta=$ $103.25(3)^{\circ} ; V=11690.3 \AA^{3}$, and $Z=2$. Anisotropic (heavy atoms)-isotropic (rigid-body phenyl rings) refinement gave $R_{1}=7.0 \%$ for 3014 independent reflections ( $2 \theta \leq 45^{\circ}$ ) with $I>3 \sigma$.

Figure 1. Molecular architecture of the 25 -metal-atom cluster $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{10^{-}}\right.$ $\left.\mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{PtCl}_{7}\right]^{+}$(3), as the $\mathrm{Cl}^{-}$salt: (a) the metal core, $\mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{Pt}$; (b) the metal-ligand framework, $\mathrm{P}_{10} \mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{PtCl}_{7}$; (c) projection of the two silver pentagons onto the crystallographic mirror which passes through $\mathrm{Aul3}$ and the five doubly bridging chloride ligands $\mathrm{Cll}-\mathrm{Cl} 5$. Atoms AP11 and AP11' (centers of icosahedra) represent an equal admixture of Au and Pt due to the crystallographically imposed mirror ( $C_{s}-\mathrm{m}$ ) symmetry. Atoms related by the mirror symmetry are designated as primes. All radial bonds ( 12 each) from AP11 and AP11' have been omitted for clarity. Some important distances are $(\AA): A P 11-A u(n)$, 2.687(av); AP11-Ag(n), 2.810(av); AP11-Ag11, 2.767(2); AP11-Aul3, 2.824(7); $\mathrm{Aul3}-\mathrm{Ag}(\mathrm{n}), 2.873(\mathrm{av})$. Intrapentagonal: $\mathrm{Au}(\mathrm{n})-\mathrm{Au}(\mathrm{n}+1)$, $2.888(\mathrm{av}) ; \mathrm{Ag}(\mathrm{n})-\mathrm{Ag}(\mathrm{n}+1), 2.898(\mathrm{av})$. Interpentagonal: $\mathrm{Ag}(n)-\mathrm{Ag}-$ ( $n^{\wedge}$ ), 2.949 (av) where $n=1-5$; Au-P, 2.30(av); Ag11-Cl11, 2.389(5); $\mathrm{Ag}(n)-\mathrm{Cl}(n), 2.50$ (av) where $n=1-5$. The five doubly bridging chloride ligands form a slightly distorted pentagon with nonbonding distances $(\AA)$ of: $\mathrm{Cl} 1 \cdots \mathrm{Cl} 2,4.87, \mathrm{Cl} 2 \cdots \mathrm{Cl} 3,5.15, \mathrm{Cl} 3 \ldots \mathrm{Cl} 4,5.31, \mathrm{Cl} 4 \cdots \mathrm{Cl} 5,5.28$, and $\mathrm{Cl1} \cdots \mathrm{Cl} 5,5.69$.
$\mathrm{Ph}_{3} \mathrm{P}$ groups coordinate to 10 surface Au atoms in a radial fashion. As shown in Figure 1c, there are five doubly-bridging chloride ligands ( $\mathrm{Cl} 1-\mathrm{Cl} 5$ ) connecting the two inner $\mathrm{Ag}_{5}$ pentagons. Two more chloride ligands ( $\mathrm{Cl11}$ and $\mathrm{Cl11}^{\prime}$ ) coordinate terminally to the two apical Ag atoms ( Ag 11 and $\mathrm{Ag} 11^{\prime}$ ).

Several novel features of the structure of $\mathbf{3}$ are noteworthy. First, the most significant structural characteristic of $\mathbf{3}$ is that

[^1]one of the two centers of icosahedra is occupied by the unique Pt atom. ${ }^{14}$ Second, the shared vertex is Au , as in the majority of the bimetallic biicosahedral ( $\mathrm{Au} / \mathrm{Ag}$ ) supraclusters. ${ }^{8}$ Third, the observed metal configuration is exactly ses instead of nearly ses as in 2. Fourth, there are five symmetrical-bridging chloride ligands in $\mathbf{3}$ instead of $s i x$ as in $\mathbf{1 b}$. Fifth, while $\mathbf{1 b}$ is a monocation and $\mathbf{2}$ is a dication, $\mathbf{3}$, with a Pt atom replacing one of the Au atoms, is a monocation (vide infra).
The intermetallic bonding distances follow the trends (presumably bond strength in reversed order) of: (1) $\mathrm{Pt}-\mathrm{Au}<\mathrm{Pt}-$ $\mathrm{Ag}<\mathrm{Au}-\mathrm{Au} \leq \mathrm{Au}-\mathrm{Ag}<\mathrm{Ag}-\mathrm{Ag} ;$;-11 (2) $\mathrm{M}_{\mathrm{c}}-\mathrm{M}_{\mathrm{s}}<\mathrm{M}_{\mathrm{c}}-\mathrm{M}_{\mathrm{r}}<$ $\mathrm{M}_{\mathrm{v}}-\mathrm{M}_{\mathrm{s}}<\mathrm{M}_{\mathrm{s}}-\mathrm{M}_{\mathrm{s}}$ (where $\mathrm{c}, \mathrm{v}$, and s denote centers of icosahedra, shared vertex, and "surface" metal atoms, respectively); and (3) intraicosahedral <intericosahedral. These structural trends can be rationalized in terms of the disparities in cohesive energy and in electronegativity. The latter is related to the relativistic effects. ${ }^{15}$ These structural trends and their electronic origins provide strong evidence for the cluster of clusters ${ }^{5-10}$ concept, in which the individual icosahedral units serve as basic building blocks.

Finally, the observation of $\mathbf{3}$ suggests the existence of a parallel sequence of trimetallic ( $\mathrm{Au} / \mathrm{Ag} / \mathrm{Pt}$ ) vertex-sharing polyicosahedral supraclusters, from a single icosahedron of 13 metal atoms to an icosahedron of icosahedra of 127 metal atoms, in analogy to the bimetallic ( $\mathrm{Au} / \mathrm{Ag}$ ) vertex-sharing polyicosahedral clusters. ${ }^{5-10}$ Within the bicosahedral series, preliminary studies ${ }^{16}$ suggest the existence of a series of 25 -metal-atom trimetallic ( $\mathrm{Au} / \mathrm{Ag} / \mathrm{Pt}$ ) clusters of general formulas [ $\left.\left(\mathrm{R}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{11} \mathrm{Ag}_{12} \mathrm{Pt}_{2} \mathrm{X}_{7}\right]$ (4) and [ $\left(\mathrm{R}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{12} \mathrm{Ag}_{12} \mathrm{PtX} 8$ ] (5), as depicted in Chart I. In fact, 2,3, and 4 are members of the 5 -ring (Chart I, top) series $\left[\left(\mathrm{R}_{3} \mathrm{P}\right)_{10} \mathrm{Au}_{13-n-m} \mathrm{Ag}_{12+n} \mathrm{M}_{m} \mathrm{X}_{7}\right]^{(2-m)+}(m=0-2)$, whereas 1 and 5 are members of the 6 -ring series $\left[\left(R_{3} P\right)_{10} \mathrm{Au}_{13-n-m^{-}}\right.$ $\left.\mathrm{Ag}_{12+n} \mathrm{M}_{m} \mathrm{X}_{8}\right]^{(1-m)+}(m=0,1)$, where $n=0,1 ; \mathrm{R}=$ aryl, alkyl; $\mathrm{M}=\mathrm{Pt}, \mathrm{Pd}, \mathrm{Ni}$; and $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}$. All of these biicosahedral clusters satisfy the $\mathrm{M}-\mathrm{X}-\mathrm{Q}=8 n=16$ electrons ${ }^{7 \mathrm{a} .17}$ rule where $\mathrm{M}, \mathrm{X}, \mathrm{Q}$ refer to the numbers of Au or Ag atoms, halide ligands, and the overall charge, respectively. (Note that each group 11 or 10 metal atom contributes one or zero electron for cluster bonding, respectively.) The new synthetic strategy (reductive addition of a third metal to a preformed bimetallic cluster) reported here, in combination with those developed for the bimetallic ( $\mathrm{Au} / \mathrm{Ag}$ ) system ${ }^{5-10}$ (cluster of clusters approach), should allow a systematic design and synthesis of a new highnuclearity trimetallic ( $\mathrm{Au} / \mathrm{Ag} / \mathrm{Pt}$ ) vertex-sharing polyicosahedral cluster sequence (work in progress).
