#### Abstract

The reactivity of the two isoelectronic cations ( $\mathrm{Hg}^{2+}$ and $\mathrm{Tl}^{3+}$ ) toward the cyclopropane ring is compared, and further evidence for the exclusive corner selectivity for $\mathrm{Hg}^{2+}$ is provided by isotope labeling. Cleavage of cyclopropyl derivative 1 with $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2}$, followed by KBr quenching, afforded the stable, rearranged organomercurial 3, whose transmetalation has been studied. Whereas reaction of $\mathbf{3}$ with Pd (II) afforded lactol 4, treatment with $\mathrm{Me}_{2} \mathrm{CuLi}$ resulted in the formation of cyclobutanol derivative ( $\mathbf{3} \boldsymbol{\rightarrow 2 9}$ ); a nalogous conjugate addition has also been accomplished ( $32 \rightarrow 35$ ). Similarly, the organomercurial 22, obtained from 21 as the major product on the Hg (II)-mediated ringopening, reacted with $\mathrm{Me}_{2} \mathrm{CuLi}$ or $\mathrm{AlCl}_{3}$ to give the ring-closure product 21. These reactions represent a novel method for the stereoselective construction of four- and three-membered rings. The stereochemistry of the key steps of these transformations has been established by using stereospecifically deuterated substrates $\mathbf{1 b}, \mathbf{3 b}$, 21b, and 22b.

## Introduction

Activation of organic substrates by both transition and nontransition metals ${ }^{1}$ has the promise of controlling reactivity, enhancing selectivity and efficiency of chemical transformations, and achieving synthetic goals that cannot be attained by traditional methods. ${ }^{2}$ Further avenues can be opened by transmetalation, ${ }^{1,3}$ a methodology that combines (often in one pot) the benefits of specific reactivities of two or more metals in tandem reactions.

Stereocontrolled cyclopropanation, ${ }^{4.5}$ catalyzed by various metals, ${ }^{6}$ followed by ring-opening, ${ }^{4}$ is an attractive strategy for construction of up to three contiguous chiral centers. ${ }^{2}$ However, the mechanism of cleavage of the cyclopropane ring was only little understood until very recently, ${ }^{7}$ which has considerably hampered a wider synthetic application of this reaction.

Revitalization of interest in cyclopropane scission in the last few years has led to defining certain relations between the mechanism and the reagent employed. ${ }^{7}$ Thus, electrophilic opening by reagents capable of back-donation, such as transition metals ( $\mathrm{Pd}, \mathrm{Pt}$, and Rh$)^{8}$ and halogens ( Cl and Br ), ${ }^{9}$ is now known to occur via a stereospecific "edge" attack, resulting in retention of configuration at the carbon to which the electrophile becomes linked (Scheme 1). Alternative "corner" opening has also been considered, ${ }^{7,10}$ but there was a lack of direct evidence in support

[^0]Scheme 1

of this mechanism and this issue has been a subject of controversy. Using double isotopic labeling ( ${ }^{2} \mathrm{H}$ and ${ }^{18} \mathrm{O}$ ), we have recently shown, for the first time, that thallium(III) is capable of stereospecific "corner" activation and have decribed a unique skeletal rearrangement (Scheme 2) of $3 \alpha, 5$-cyclo-5 $\alpha$-cholestan$6 \alpha$-ol (1 $\boldsymbol{2} \rightarrow 4$ ). ${ }^{11}$ While this project was in progress, exclusive "corner" opening was also observed with other poor back-donors, namely, with a proton ${ }^{12}$ and with mercury(II). ${ }^{12-14}$

## Scheme 2

Herein we compare the reactivity of the two isoelectronic cations ( $\mathrm{Tl}^{3+}$ and $\mathrm{Hg}^{2+}$ ) in cyclopropane ring-opening, offer further evidence for the preferential corner selectivity for $\mathrm{Hg}^{2+}$, and report on the outcome of transmetalation with various metals ( $\mathrm{Pd}, \mathrm{Li}$, and Cu ) of the stable organomercurials arising from the cyclopropane opening. In this study we have employed three readily available cyclopropyl derivatives 1,7 , and 21 .

## Results

Cyclopropane Ring-Opening by $\mathbf{H g}$ (II) and Tl (III) in Steroidal Derivative 1. Treatment of steroidal cyclopropyl alcohol ${ }^{15}$ 1a with $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ in DME- $\mathrm{CH}_{3} \mathrm{CN}(2: 5)$ at room temperature

(16) The structure was determined by NMR spectra using H,H-COSY, P.E. COSY, and NOESY, ${ }^{17} \mathrm{HMQC}$, HSQC, and multiple bond HSQC, 18 , HMBC, ${ }^{18}$ and DEPT and selective INEPT. ${ }^{19}$ i H NMR: 9.72 ( $\mathrm{s}, 1 \mathrm{H}, \mathrm{CHO}$ ). ${ }^{13} \mathrm{C}$ NMR: $34.78\left(\mathrm{CH}_{2} \mathrm{HgBr}\right), 206.22$ (CHO). ${ }^{199} \mathrm{Hg}$ NMR: $-1063 \mathrm{ppm} .{ }^{20}$ The full assignment of carbon signals in the ${ }^{13} \mathrm{C}$ NMR spectrum has been achieved.
for 1.5 h led, after KBr workup, to a single product $3 \mathrm{a}^{16}$ in $97 \%$ isolated yield (Scheme 2). ${ }^{21}$ In contrast to the Tl (III)-mediated reaction, ${ }^{11}$ where the organothalliated species 2 a undergoes an instantaneous conversion to lactol 4a, the organomercurial 3a could be isolated as a stable compound.

This reaction appears to be unique as it is limited solely to $\mathrm{Hg}^{2+}$ and $\mathrm{Tl}^{3+}$ (strong, soft Lewis acids ${ }^{22}$ ). Other isoelectronic cations ( $\mathrm{Au}^{+}$and $\mathrm{Pb}^{4+}$ ) and those of high redox potential as well as other ions $\left(\mathrm{Ce}^{4+}, \mathrm{Cu}^{+}, \mathrm{Cu}^{2+}, \mathrm{Ag}^{+}, \mathrm{Mn}^{3+}, \mathrm{Al}^{3+}, \mathrm{In}^{3+}\right.$, and $\mathrm{Ti}^{4+}$ ) were found either to be inert or to convert 1a to cholesterol or its esters (acetate, nitrate, etc.). Cholesteryl tosylate was formed on reaction with $\mathrm{PhI}(\mathrm{OH}) \mathrm{OTs}$. Transition metals, such as Pd, Pt , and Rh , turned out either to be inert (presumably due to steric hindrance in 1) or to trigger a rearrangement to cholesteryl derivatives (e.g. with $\mathrm{PdCl}_{2}$ ) at higher temperature and prolonged reaction time. The latter reaction can be ascribed to the inherent acidity of $\mathrm{PdCl}_{2}$.

Mechanism of $\mathbf{H g}$ (II)-Mediated Ring-Opening in Cyclopropyl Alcohol 1 and Transmetalation of Hg for Pd in Organomercurial 3. We assumed that the stereochemistry of cyclopropane fission could be established in a way analogous to that which we have employed for thallium, ${ }^{11}$ i.e. by using stereospecifically deuterated cyclopropyl alcohol 1b. ${ }^{23}$ To this end, we needed to assign the NMR signals of the two diastereotopic protons at C(4) in the product of cleavage. In the spectrum of 3 a , they appeared at $1.93 \mathrm{ppm}(\mathrm{dd}, J=8.7$ and $J=11.7 \mathrm{~Hz}$ ) and $2.05(\mathrm{dd}, J=8.1$ and $J=11.7 \mathrm{~Hz}$ ), respectively. However, the similarity in their coupling constants was suggestive of relatively free rotation about the $\mathrm{C}(3)-\mathrm{C}(4)$ bond so that the assignment was not possible at this stage. ${ }^{26}$ Hence, transformation of 3 a to a compound in which the $\mathrm{C}(3)-\mathrm{C}(4)$ bond was conformationally fixed was required. After much experimentation, Pd (II) was found to convert 3a to lactol 4 a or acetal 5 a (via 6 a ), in which $4 \alpha-\mathrm{H}$ and $4 \beta-\mathrm{H}$ were easily identified. ${ }^{27}$ Similarly, excess of $\mathrm{Br}_{2}$ (or NBA) transformed 3a to the corresponding lactone.

Having found the means for an unequivocal assignment of the NMR signals for the two protons at C(4), we could now carry out experiments with labeled compounds. Stereospecifically labeled cyclopropyl derivative 1b was treated with $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and quenched with aqueous KBr in the same way as was the unlabeled analogue 1a. Analysis of the ${ }^{1} \mathrm{H}$ NMR spectrum of the product 3 b revealed the absence of the lower field resonance ( 2.05 ppm ), while the upfield signal at 1.93 ppm was changed to a doublet ( $J=8.7 \mathrm{~Hz}$ ). This indicated that the reaction was stereohomogeneous ( $\geq 98 \%$ ). Catalytic reaction with $\mathrm{Li}_{2} \mathrm{PdCl}_{4}$ ( $5 \mathrm{~mol} \%$; generated from $\mathrm{PdCl}_{2}$ and LiCl ) and $\mathrm{CuCl}_{2}$ ( 5 equiv) in DME/ $\mathrm{H}_{2} \mathrm{O}$, which is assumed to proceed with retention of

[^1]configuration ${ }^{28,29}$ via $\mathbf{6 b}$, furnished lactol $\mathbf{4 b}$, while in the presence of MeOH , methyl acetal $\mathbf{5 b}$ was formed. A stoichiometric reaction, in which only $\mathrm{Li}_{2} \mathrm{PdCl}_{4}$ (1.1 equiv) was added, gave the same result. The configuration of deuterium as being $4 \beta$ was inferred from the ${ }^{1} \mathrm{H}$ NMR spectra of the respective products: in the labeled compounds, the absence of the higher field signal $(3.40 \mathrm{ppm})$ and the conversion of the lower field doublet of doublets at 4.17 ppm into a doublet ( $J=9.2 \mathrm{~Hz}$ ) are compatible only with the $4 \beta-{ }^{2} \mathrm{H}$ configuration; ${ }^{27}$ the other stereoisomer could not be detected. ${ }^{30}$

Heumann and Bäckvall have shown ${ }^{28}$ that $\mathrm{Pd}-\sigma$-complexes generated, for example, from organomercurials by the $\mathrm{PdCl}_{2}$ / $\mathrm{CuCl}_{2}$ method undergo $\mathrm{S}_{\mathrm{N}} 2$ substitution by $\mathrm{Cl}^{-}$to give alkyl chlorides. Hence, lactol 4 b could be conjectured to arise from the initially formed chloride by a second inversion. To rule out this possibility, the reaction was run under the chloride-free conditions, with a stoichiometric amount of palladium triflate, generated in situ from ( AcO$)_{2} \mathrm{Pd}$ and $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$. The product (4b) was identical with that formed by the $\mathrm{PdCl}_{2} / \mathrm{CuCl}_{2}$ method. Apparently, the intramolecular $\mathrm{S}_{\mathrm{N}} 2$ substitution is highly favored in 6 by the steric arrangement which suppresses the intervention of $\mathrm{Cl}^{-},-31,32,34$ These experiments thus provided conclusive evidence for the mechanism of the whole sequence and showed that opening of the cyclopropane ring in 1 by $\mathrm{Hg}($ II $)$ occurred solely in a corner fashion.

Cyclopropane Ring-Opening by $\mathbf{H g}$ (II) and Tl (III) inSteroidal Hydrocarbon 7. In the absence of the $6 \alpha$-hydroxy group, as in the hydrocarbon 7 , the reaction with $(\mathrm{AcO})_{2} \mathrm{Hg}$ has been reported to proceed via a simple ring-opening followed by elimination to give the acetate of the corresponding allylic alcohol 11 (Scheme 3). ${ }^{35}$ The reaction was believed to be initiated by an edge attack of Hg (II). ${ }^{35}$ In light of the evidence accumulated by us and by other investigators, ${ }^{12-14}$ this interpretation seems doubtful. Now, we have found that Tl (III) reacts in a similar way, giving a 72:28 mixture of allylic alcohols 11 and $12,{ }^{36}$ presumably via allylic cation 10. ${ }^{38}$ These reactions demonstrate that the presence of the $6 \alpha$-hydroxy group is not a prerequisite for the regioselective cleavage between the most (C-5) and the least substituted (C-4) carbon of the cyclopropyl ring. The initial formation of the most

## Scheme 3

Scheme 4

stable carbocation 8 appears to be the driving force for the reaction. While here the elimination $(8 \rightarrow 9)$ seems to be the energetically cheapest subsequent process, in the case of cleavage of 1 the initial ring-opening is followed by Wagner-Merrwein migration of C-7.

Cyclopropane Ring-Opening by $\operatorname{Pd}$ (II) in Cyclopropyl Olefin 13. While on treatment with Pd (II) cyclopropyl alcohol 1a gave only cholesteryl derivatives due to preferential attack on hydroxyl (see above), hydrocarbon 7 was either inert to the same reagents (at room temperature) or afforded an intractable mixture of lipophilic products (at elevated temperature). On the other hand, introduction of a double bond in the 6,7-position, as in 13, had a dramatic effect (Scheme 4). ${ }^{39}$ Thus, on treatment with $\left(\mathrm{CH}_{3}\right.$ $\mathrm{CN})_{2} \mathrm{PdCl}_{2}$ in methanol at room temperature for $20 \mathrm{~h}, 13$ was converted into the $\eta^{3}$-complex 15 ( $93 \%$ ). The structure of 15 was corroborated by combination of spectral methods (namely NMR) and chemical correlation: reduction of 15 with $\mathrm{LiAl}^{2} \mathrm{H}_{4}$ (which is assumed to proceed stereoselectively via a syn-delivery of hydride from Pd$)^{1}$ afforded deuterated olefin 16, for which the $7 \alpha-{ }^{2} \mathrm{H}$ configuration was confirmed by the coupling constant $J_{6-\mathrm{H}, 7 \beta \cdot \mathrm{H}}$ $=5.4 \mathrm{~Hz}$. The ring-opening in 13 is apparently boosted by initial coordination of $\mathrm{Pd}(\mathrm{II})$ to the double bond (14) and occurs via an edge attack on the $C(3)-C(5)$ bond.

Mercury(II)-Mediated Ring-Opening in Cyclopropyl Derivative 21. In order to further explore the reactivity of the cyclopropane

[^2]
## Scheme $5^{a}$

${ }^{a}$ Mes $=\mathrm{CH}_{3} \mathrm{SO}_{2}$.
ring toward Hg (II) and the transmetalation of the resulting organomercurials, another model compound has been synthesized, namely, 20 (Scheme 5). ${ }^{40}$ In this case, preferential cleavage of the $\mathrm{C}(5)-\mathrm{C}(19)$ and /or $\mathrm{C}(10)-\mathrm{C}(19)$ bond was anticipated ${ }^{41}$ in accordance with the apparently general regioselectivity observed, e.g., with 1 (the bond between the most and the least substituted carbon). This cleavage would create an electron-deficient center at $C(5)$ and/or $C(10)$, whose stabilization by proton elimination could produce up to four isomeric olefins. In order to minimize the number of expected products, we have prepared ketone 21a because, in this instance, the C(5)-cation should produce only a conjugated ketone. The deuterated derivative 21b was prepared from the aldehyde 17 employing a literature procedure (Scheme 5):40,42 reduction of aldehyde 17 with $\mathrm{NaB}^{2} \mathrm{H}_{4}$ afforded the deuterated alcohol 18b as a $70: 30$ mixture of $\mathrm{C}(19)$-epimers. ${ }^{42}$ Mesylation followed by reaction with $\mathrm{LiAlH}_{4}$ afforded cyclopropyl alcohol 20b, ${ }^{43}$ oxidation of which with Jones' reagent furnished the desired ketone 21b as a 68:32 mixture of C(19)-epimers. ${ }^{44}$ We have now found that the aldehyde 17 can be reduced with $\mathrm{LiAl}^{2} \mathrm{H}\left(\mathrm{OBu}^{t}\right)_{3}$ (generated in situ from 1 mol of $\mathrm{LiAl}^{2} \mathrm{H}_{4}$ and 3 mol of tert-butyl alcohol) to give 18b as an 85:15 epimeric mixture. The latter alcohol was converted to the cyclopropyl ketone 21b ( $84: 16$ ) using the same procedure as before (Scheme 5).
Treatment of 21a with $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ in DME at $0^{\circ} \mathrm{C}$ for 2 h led, after KBr workup, to a mixture of three olefinic organomercurials 22a, 24a, and 25a (Scheme 6). ${ }^{45}$ The structures of 22a and 25a were corroborated by chemical correlation: upon

[^3]
## Scheme 6

$\mathrm{Bu}_{3} \mathrm{SnH}$ reduction, 22a furnished the known cholest-4-en-3-one (23), while 25a afforded the Westphalen-type ketone 26, identicalwith an authentic sample. ${ }^{46,47}$ The structure of 24a was deduced from spectral data. ${ }^{48}$

The reaction of the deuterated cyclopropyl derivative 21b with $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{3}$ proceeded analogously giving 22b, 24b, and 25 b . The reaction was highly stereospecific: starting from a 68:32 mixture of 21b and its $\mathrm{C}(19)$-epimer, 22b turned out to be a $65: 35$ mixture of $\mathrm{C}(19)$-epimers as revealed by ${ }^{2} \mathrm{H}$ NMR; a similar composition was detected for 24b (68:32). ${ }^{49}$ This outcome corresponds to $96 \%$ and $100 \%$ diastereoselectivity, respectively, which is within the experimental error of the ratio determination by ${ }^{1} \mathrm{H}$ and ${ }^{2} \mathrm{H}$ NMR. Since the configuration at $\mathrm{C}(19)$ of these organomercurials could not be safely established from their NMR spectra, we sought a suitable chemical correlation that would address this issue. We reasoned that a stereospecific ring-closure reaction employing the carbon adjacent to mercury, as a nucleophile, and an electrophilic neighboring group ( $\mathrm{C}=\mathrm{O}$ or $\mathrm{C}=\mathrm{CC}=\mathrm{O}$ ) might provide the required tool. Utilizing $\mathbf{3 b}$ (of known configuration at C-4) as a model compound, we have therefore endeavored to find conditions under which such reactions occur.

Transmetalation of Hg for Li and Cu in Organomercurial 3 and Construction of a Cyclobutane Ring. In order to bring about an intramolecular addition to the aldehyde group which would construct a four-membered ring in a novel way, we have attempted a transmetalation of 3a that would generate a more reactive organometallic species. ${ }^{50,52}$ Organolithium reagents (MeLi, $n-\mathrm{BuLi}$, and $t-\mathrm{BuLi}$ ) proved unrewarding as they produced complex mixtures. We reasoned that intermediates derived from

[^4]Scheme 7

softer metals might be more promising, and after several unsuccessful attempts using various transition metals, we turned our attention to copper ${ }^{53}$ (Scheme 7). Rather surprisingly, MeCu effected clean methylation on mercury, providing the MeHg derivative 27 (94\%). This result itself may represent a new method for the preparation of dialkyl mercury derivatives $\mathrm{RHgR}^{\prime}$ from the readily available organomercury halides RHgBr . Other reagents that also gave high yields of 27 were $\mathrm{Me}_{3} \mathrm{Al}$ (69\%) and $\mathrm{Me}_{2} \mathrm{Zn}$ (91\%).

Subsequent treatment of $\mathbf{2 7}$ with MeLi at low temperature resulted in the formation of the desired cyclobutanol 29a (73\%). Alternatively, 29a was obtained in one pot on reaction of 3a with $\mathrm{Me}_{2} \mathrm{CuLi}$ in an excellent yield (93\%). This reaction can be understood in terms of the Lipshutz equilibrium between a cuprate and alkyllithium ( $2 \mathrm{Me}_{2} \mathrm{CuLi} \rightleftarrows \mathrm{MeLi}+\mathrm{Me}_{3} \mathrm{Cu}_{2} \mathrm{Li}$ ). ${ }^{54,55}$

The stereostructure of cyclobutanol 29a was corroborated by combination of NMR spectroscopy and chemical transformations: (1) Upon irradiation of $10 \beta-\mathrm{CH}_{3}$, an NOE ( $5.7 \%$ ) was observed for CHOH which is compatible only with an $\alpha$-configuration for the hydroxyl. (2) Alcohol 29a was oxidized with Jones' reagent to ketone 30a, whose $\nu_{\mathrm{C}}=0=1750 \mathrm{~cm}^{-1}$ was in the range typical for cyclobutanones. ${ }^{57}$ (3) On reduction with $\mathrm{LiAlH}_{4}$, ketone 30a

[^5]Scheme 8

35

34
furnished alcohol 31,59 epimeric with 29a, for which no NOE for CHOH and $10 \beta-\mathrm{CH}_{3}$ could be observed.

When deuterated organomercurial 3b was subjected to the reaction with $\mathrm{Me}_{2} \mathrm{CuLi}$, a stereospecifically deuterated cyclobutanol 29 b was obtained. In this case, the $4 \alpha$-configuration of deuterium was determined in ketone 30b, ${ }^{60}$ which was prepared from 29b by Jones' oxidation. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{3 0 b}$ also revealed a ca. $86 \%$ diastereoisomeric purity, which in view of the label content, indicates $\geq 90 \%$ overall retention of configuration at $C(4)$. This result is compatible with double retention of configuration at $C(4)$ through the whole sequence and with a mechanism for the cyclization step comprising intramolecular coordination of the metal to the carbonyl oxygen.

Having thus successfully accomplished intramolecular addition to the $\mathrm{C}=\mathrm{O}$ bond to produce cyclobutanol 29 , we explored the possibility of an intramolecular conjugate addition to an activated $\mathrm{C}=\mathrm{C}$ bond. The required substrate, $\alpha, \beta$-unsaturated ester 32, was prepared from aldehyde 3a on Horner-Emmons olefination with (EtO) ${ }_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{Et}$ and BuLi in refluxing THF (Scheme 8). Although the reaction was rather slow (reflux for 12 h ) due to steric hindrance, the yield of 32 was good ( $73 \%$ ). To our knowledge, this is the first successful Wittig-type olefination in the presence of an HgBr group in the substrate molecule. ${ }^{61}$ The organomercurial 32 was first methylated with MeCu or $\mathrm{Me}_{3} \mathrm{Al}$ to give 33 (in $91 \%$ and $95 \%$ yield, respectively). In contrast to 27, however, reaction of 33 with MeLi or BuLi produced a complex mixture; $\mathrm{Me}_{2} \mathrm{CuLi}$ proved more efficient, furnishing the desired cyclobutane derivative 35 (40\%). A much better yield of 35 ( $75 \%$ ) was obtained in one pot from 32 on reaction with $\mathrm{Me}_{2}$ CuLi . This behavior suggests that the actual reactive species 34 involves copper. Although the structure of 34 is speculative, it seems reasonable to assume ${ }^{33}$ that $\mathrm{M}=\mathrm{CuLiCH}_{3}$ or $\mathrm{CuHgLiCH}_{3}$ and that the more suitably positioned $\mathrm{C}(4)$ in the complex 34 adds across the double bond in preference to the $\mathrm{CH}_{3}$ group.

[^6]
## Scheme 9

Finally, treatment of 33 (first generated in situ from 32 by means of $\mathrm{Me}_{3} \mathrm{Al}$ ) with $\mathrm{Me}_{3} \mathrm{Al} / n-\mathrm{BuLi}$ furnished 35 in $92 \%$ isolated yield. ${ }^{62,63}$

Stereoselective Skeletal Rearrangement of Organomercurial 3 by Means of Lewis Acids. In the previous paragraph, we have described stereoselective ring-closures ( $3 \rightarrow 29$ and $32 \rightarrow 35$ ) via activating the nucleophilic component in the molecule ( $\mathrm{C}-\mathrm{Hg}$ ). Another possibility was to activate the electrophilic group ( $\mathrm{C}=\mathrm{O}$ ) by coordination to a Lewis acid. As mentioned above, $\mathrm{Me}_{3} \mathrm{Al}$ (a weak Lewis acid) only effected methylation on mercury ( $3 \mathrm{a} \rightarrow$ $27 a$ and $32 \rightarrow 33$ ). By contrast, we have now found that the reaction of 3 a with $\mathrm{AlCl}_{3}$ (a strong Lewis acid) takes a completely different course, producing 38a (Scheme 9). Similar reaction was also observed with $\mathrm{MoCl}_{5}{ }^{64}$ and $\mathrm{SiCl}_{4}$. This unexpected outcome can be rationalized as follows: the reagent $\left(\mathrm{AlCl}_{3}\right)$ apparently activated the $\mathrm{C}=\mathrm{O}$ group in 3a by coordination to the oxygen. However, instead of closing a four-membered ring by reacting with the nucleophilic carbon $\mathrm{C}(4)$, this coordination triggered a stereoelectronically controlled Wagner-Meerwein migration of $\mathrm{C}(7)$ from $\mathrm{C}(5)$ to $\mathrm{C}(6)$, generating carbocation 36a. The latter cationic species is likely to form a bond between $\mathrm{C}(4)$ and $\mathrm{C}(5)$, which may, presumably, occur with inversion at $\mathrm{C}(4)$, as suggested by the geometry of $\mathbf{3 6 a}$ (this sequence may well be concerted). The resulting cyclopropyl intermediate 37a subsequently collapses to cholesteryl chloride (38a) via the wellknown ${ }^{65}$ "iso-steroid" rearrangement.

The mechanism was verified by labeling. The deuterated organomercurial 3a was treated with $\mathrm{AlCl}_{3}$ in $\mathrm{Et}_{2} \mathrm{O}$ as was its unlabeled counterpart. Analysis of the ${ }^{1} \mathrm{H}$ NMR spectrum of the resulting deuterated cholesteryl chloride 38b established the configuration of deuterium as being $4 \beta^{66}$ and revealed that the whole reaction sequence was remarkably stereoselective, as no other diastereoisomer could be detected. The $4 \beta-2 \mathrm{H}$ configuration

[^7]Scheme 10

is compatible with inversion of configuration at $\mathrm{C}(4)$ in the $\mathrm{C}(4)-$ $\mathrm{C}(5)$ bond-forming step ( $\mathbf{3 6 b} \rightarrow \mathbf{3 7 b}$ ). ${ }^{67}$
Transmetalation of Hg for Li and Cu in Organomercurial 22 and Construction of a Cyclopropane Ring. Having found the means for the stereoselective construction of a $\mathrm{C}-\mathrm{C}$ bond between the carbon adjacent to mercury and an electrophilic center ( $C=0$, $\mathrm{C}=\mathrm{CC}=\mathrm{O}$, or $\mathrm{C}^{+}$), which worked remarkably well for 3 and 32 , we set out to explore the reactivity of the unlabeled organomercurial 22a with the aim to close up a cyclopropane ring. To our delight, $\mathrm{Me}_{2} \mathrm{CuLi}$ was found to induce cyclization, resulting in the formation of 21a ( $86 \%$ ). This highly efficient ring-closure represents a novel way for the construction of cyclopropyl derivatives and was also accomplished with $\mathrm{AlCl}_{3}$ and/or $\mathrm{SiCl}_{4}$ in good yields ( $93 \%$ and $80 \%$, respectively).

Unfortunately, the cuprate-mediated cyclization of 22b turned out to be nonstereospecific. Thus, starting from the $65: 35$ mixture of $\mathbf{2 2 b}$ and its $\mathrm{C}(19)$-epimer, which originated from the ringopening of 21b ( $68: 32$ mixture; Scheme 6 ), a mixture of 21b and 21c in a $53: 47$ ratio was formed (Scheme 10), as revealed by integration of the signals of cyclopropane protons in the ${ }^{1} \mathrm{H}$ NMR spectrum (singlets at 0.47 for 21 b and 0.51 for 21 c ). This is in sharp contrast with the highly stereohomogeneous cyclobutane ring-closure 3b $\rightarrow$ 29b (Scheme 7), where no more than $10 \%$ scrambling was observed: ${ }^{68}$ while retention of configuration at the nucleophilic carbon largely dominated the cyclobutane ring formation (Scheme 7), this pathway ( $22 b \rightarrow \mathbf{B} \rightarrow \mathbf{2 1 c}$; Scheme 10) was considerably suppressed at the expense of a competing mechanism (22b $\rightarrow \mathrm{A} \rightarrow 21 \mathrm{~b}$ ).
The latter mechanism would be in line with the inversion of the configuration at $\mathrm{C}(4)$ in the $\mathrm{AlCl}_{3}$-mediated cyclopropane ring-closure $\mathbf{3 6 b} \rightarrow \mathbf{3 7 b}$. Therefore, the cyclization of $\mathbf{2 2 b}$ by means of $\mathrm{AlCl}_{3}$ (although much slower than that with cuprate) was also explored. In this case we have observed acceptable stereoselectivity since the resulting cyclopropyl derivative turned out to be a $62: 38$ mixture of $\mathbf{2 1 b}$ and 21c, which corresponds to $95 \%$ de for the ring-closure and $91 \%$ de overall for the two-step sequence (21b $\boldsymbol{\mathbf { 2 2 b }} \boldsymbol{\rightarrow 2 1 b}$ ). Since transmetalation of Hg for
(67) A recent precedent suggests that the carbon atom adjacent to HgX can serve as an effective nucleophile to quench an electron-deficient center ( $\mathbf{i} \rightarrow \mathrm{ii}$ ), even in preference to the nucleophilic AcO group: Takemoto, Y.; Ohra, T.; Yonetoku, Y.; Imanishi, T.; Iwata, C. J. Chem.Soc., Chem. Commun. 1992, 192.

(68) Racemization has also been observed with another $\mathrm{Hg} \rightarrow \mathrm{Cu}$ transmetalation. ${ }^{\text {53a }}$

Al is unlikely, we can conclude that the crucial ring-closure occurred predominantly with inversion at $\mathrm{C}(19)(22 \mathrm{~b} \rightarrow \mathrm{~A} \rightarrow$ 21b; $\mathrm{M}=\mathrm{HgBr}$ ), which is in line with the previously observed stereochemistry ( $\mathbf{3 6} \rightarrow \mathbf{3 7}$; Scheme 9). In view of these mechanistic considerations we can assign a (19S) configuration to the organomercurial 22b (major epimer), which is consistent with a stereospecific corner opening of the cyclopropane ring in 21b (Scheme 6).

Since 21b was recovered (after the opening and ring-closure) as a 62:38 mixture of $C(19)$-epimers (Scheme 10), one can possibly argue that this ratio may reflect some sort of thermodynamic equilibration rather than a stereodefined transformation. We reasoned that this issue can be addressed by carrying out the sequence of ring-opening and ring-closure again with cyclopropane derivative 21b of higher epimeric purity (such as 84:16; see above). Treatment of the enriched derivative 21 b (84:16) with $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2}$ gaveorganomercurial 22b (Scheme 6), which was converted back to 21b on reaction with aluminum chloride. ${ }^{1} \mathrm{H}$ NMR analysis (namely the integration of the 19-H signals for the major and the minor isomer) revealed a 79:21 epimeric ratio. This corresponds to $94 \%$ diastereoselectivity for the two-step sequence, which is in excellent agreement with the overall stereoselectivity obtained for the lower isomeric ratio ( $91 \%$ de; see above). Hence, it can be concluded that the originally observed ratio reflected the stereoselectivity of the ring-closure rather than a thermodynamic equilibration. The above rationalization is thus further confirmed.

## Discussion

The observed behavior of mercury(II) parallels the reactivity of thallium(III) in both the stereo- and regioselectivity of the cyclopropane ring-opening. These results also demonstrate that both metals favor stereospecific corner opening ${ }^{69}$ and a fission of the C-C bond between the most and the least substituted carbon. This appears to be a general feature (at least for Hg ) as the same reactivity has now been observed for several structurally different compounds: for 1 and 21 (this report), for the parent cyclopropane $39^{13}$ and its methylated counterpart ${ }^{14}$ (Scheme 11), and for 41 (and its endo-annulated isomer). ${ }^{12}$ Unfortunately, direct comparison of the reactivity of Hg and Tl with the behavior of transition metals ( $\mathrm{Pd}, \mathrm{Pt}$, etc.) and $\mathrm{Br}_{2}$ could not be made with our model compounds 1 and 21 as they either are inert to these reagents or undergo different transformations (namely the conversion to cholesterol or its derivatives; see above). However, reaction of the cyclopropyl derivative 13 with $\mathrm{Pd}(\mathrm{II})$ demonstrates that edge opening is indeed possible with our type of compounds, i.e. that the polycyclic structure itself does not preclude the reagent approach on the edge. Moreover, for example, the cyclopropyl derivative 43, very closely related to 41 (which is known to be corner-opened ${ }^{12}$ with $\mathrm{Hg}^{2+}$ ), has been cleaved by Pt (a transition metal) with exclusive edge selectivity ${ }^{\text {8e }}$ (Scheme 11). In view of this experimental evidence, we are confident that the mechanism of opening (corner or edge) is dictated by the nature of the reagent rather than by the substrate structure.

The preferential edge opening by transition metals and halogens has been attributed to the back-donation from the electrophile to the LUMO Walsh orbitals, which stabilizes the transition state..$^{12,13}$ By contrast, electrophiles incapable of back-donation ( $\mathrm{H}^{+}, \mathrm{Hg}^{2+}$, and $\mathrm{Tl}^{3+}$ ) cannot provide such a stabilization, which results in the preferential corner opening. This mechanism may be further boosted by simultaneous stabilization of the developing positive charge on the other carbon of the $\mathrm{C}-\mathrm{C}$ bond being split via a homologous $\mathrm{S}_{\mathbf{N}} 2$-like reaction with an external nucleophile
(69) The stereostructures of the products of cyclopropane cleavage are most consistent with the corner activation. However, an initial edge attack cannot rigorously be excluded, provided that the initially formed edge-metalated intermediate quickly stereomutates to the corner-metalated species via a trigonal bipyramid. ${ }^{13}$

## Scheme 11

( $\mathbf{3 9} \boldsymbol{\rightarrow 4 0}$ or $\mathbf{4 1} \boldsymbol{\rightarrow 4 2 \text { ) or by the Wagner-Meerwein migration }}$ ( $\mathbf{1} \boldsymbol{\rightarrow}$ or 3 ).

The two isoelectronic cations ( $\mathrm{Tl}^{3+}$ and $\mathrm{Hg}^{2+}$ ) not only share the same reactivity in the initial step but in the following events as well, namely, the unique skeletal rearrangement ( $\mathbf{1 \rightarrow 2}$ or 3 ), The difference between Tl and Hg is only seen in the fate of the organometallics generated in this way. While the organomercurial 3 is fairly stable and can be isolated in pure state and used for subsequent transformations, its thalliated counterpart is more reactive and undergoes the nucleophilic ring-closure ( $2 \rightarrow 4$ ), This divergence in behavior serves as a clear example of how a choice of metal can be used for delicate control of the reactivity.

The reactions of organomercurials with MeLi or $\mathrm{Me}_{2} \mathrm{CuLi}$, presumably occurring via transmetalation, represent a novel methodology for cyclobutane annulation ( $3 \rightarrow 29$ and $32 \rightarrow 35$ ) that may be of general use in view of the rather limited number of alternative approaches ${ }^{70,71}$ and of the failure of radical reactions. The relatively high configurational stability of the organometallic species such as $28\left(a t-78^{\circ} \mathrm{C}\right)$ is noteworthy as it contrasts, for example, with the recently reported ${ }^{72}$ isomerization of an $\mathrm{R}-\mathrm{Li}$ intermediate (at $-78^{\circ} \mathrm{C}$ ), generated from the corresponding R-SMe compound.

A remarkable dichotomy has been observed for the steric course of the $\mathrm{C}-\mathrm{C}$ bond-forming ring-closure reactions: retention of configuration at the nucleophilic carbon in the formation of the cyclobutane ring induced by cuprates (Scheme 7) and a nonstereospecific reaction or predominant inversion of configuration in cyclopropane formation when cuprates or Lewis acids are used, respectively (compare Schemes 9 and 10). Since no difference in hybridization at the carbon atom adjacent to mercury has been observed for $3 a$ and $22 a,{ }^{73}$ the difference in reactivity must originate elsewhere. In the cyclobutane ring formation, one can assume frontal interaction of the $\sigma$-orbital of the $\mathrm{C}-[\mathrm{M}]$ bond

[^8] for 22a.

## Scheme 12

with the $\pi^{*}$-orbital of the double bond ( $\mathrm{C}=\mathrm{C}$ or $\mathrm{C}=\mathrm{O}$ ), which is presumably boosted by further coordination of $[\mathrm{M}]$ to the double bond (Scheme 12). This scenario will result in the retention of configuration (I). By contrast, a mechanism involving inversion (II) would preclude the latter stabilization of the transition state. As a result, retention (I) is favored over inversion (II). The geometric picture for the cyclopropane ring formation is dramatically different: for the retention mechanism (III), coordination of $[\mathrm{M}]$ is hardly attainable and the bonding angle $\left(\sim 109^{\circ}\right)$ also disfavors the formation of the cyclopropane ring (where a $\sim 60^{\circ}$ angle is required). ${ }^{74}$ For the inversion mechanism (IV), at least the bonding angle is much more favorable ( $\sim 71^{\circ}$ ). Naturally, inversion at the nucleophilic carbon will be energetically costly. However, it has been shown on rigid nitrogen compounds that the barrier for the flipping is lower than the activation energy of nucleophilic substitution ( $\mathbf{V}+\mathbf{V I} \rightarrow \mathbf{V I I}) .{ }^{75}$ If similar relative energy levels are assumed for the reaction of $\mathrm{C}-[\mathrm{M}]$ with an electrophilic partner, the preference for inversion in the case of cyclopropane ring-closure (IV) can be understood. Hence, for cuprates capable of coordination, retention is highly favored for the formation of a four-membered ring (I), whereas both retention and inversion mechanisms (III and IV) apparently operate when a three-membered ring is to be closed up. With Lewis acids as activators, no transmetalation is assumed to occur. Since the coordination ability of mercury is expected to be poor as compared to copper, the preferred mechanism seems to correspond to the more suitable geometry of the molecular framework and, as a result, the reaction predominantly occurs with inversion (IV).

## Conclusions

In conclusion, we have achieved a unique regio- and stereoselective opening of a cyclopropane ring by $\mathrm{Tl}(\mathrm{III})$ or $\mathrm{Hg}(\mathrm{II})$, followed by a skeletal rearrangement, to generate a " 5,5 " system ( $\mathbf{1} \boldsymbol{\rightarrow} \mathbf{2}$ or 3 ). Stereospecific deuteration ( $\mathbf{1 b}$ and 21 b ) provided further evidence to support the concept of preferred corner opening ${ }^{69}$ of the cyclopropane ring by poor back-donors $\left(\mathrm{H}^{+}\right.$, $\mathrm{Hg}^{2+}$, and $\mathrm{Tl}^{3+}$ known to date).

By virtue of specific transmetalations (with $\mathrm{Pd}, \mathrm{Li}$, or Cu ) and/or reactions with Lewis acids, we have been able to effect stereoselective transformations of the organomercurials 3 and 22, initially generated by the cyclopropane ring-opening. Our results have further demonstrated the potential of the transmetalation methodology. Combining the reactivity of $\mathrm{Hg}^{2+}$, which is the only reactive species capable of the cyclopropane ringopening in this unique way (as illustrated, for example, in Scheme 2), with the reaction potential of other metals, enabled us to achieve different synthetic goals: (1) the Pd -mediated intramolecular $\mathrm{S}_{\mathrm{N}} 2$ displacement ( $3 \rightarrow 6 \rightarrow 4$ ); (2) the unprecedented Cu -facilitated construction of the cyclobutane ring via the

[^9]intramolecular addition to a carbonyl group ( $3 \rightarrow 29$ ) or to an activated double bond ( $\mathbf{3 2} \rightarrow 35$ ); (3) the novel cuprate- or Lewis acid-mediated cyclopropane ring-closure via a conjugate addition (22 $\boldsymbol{\rightarrow} \mathbf{2 1}$ ). Although the experiments were confined to the steroidal skeleton, we are confident that our findings are of a general nature and may be used for synthetic purposes, particularly in view of a number of methods for preparation of organomercurials.

## Experimental Section

General Methods. Melting points were determined on a Kofler block and are uncorrected. The optical rotations were measured in $\mathrm{CHCl}_{3}$ with a Perkin-Elmer 141 polarimeter at $22^{\circ} \mathrm{C}$ with an error of $< \pm 1^{\circ}$. The NMR spectra were recorded for $\mathrm{CDCl}_{3}$ solutions at $25^{\circ} \mathrm{C}$ on a Varian Unity 400 (operating at 400 MHz for ${ }^{1} \mathrm{H}, 100.6 \mathrm{MHz}$ for ${ }^{13} \mathrm{C}$, and 61.4 MHz for ${ }^{2} \mathrm{H}$ ), Varian XL-300, or Bruker AM 300 spectrometer. Chemical shifts were indirectly referenced to TMS via the solvent signals ( 7.26 ppm for ${ }^{1} \mathrm{H}$ and ${ }^{2} \mathrm{H}$ and 77.0 ppm for ${ }^{13} \mathrm{C}$ ). The ${ }^{199} \mathrm{Hg}$ NMR spectra were recorded on a Varian XL-300 instrument (at 53.7 MHz ) and referenced to external $\mathrm{Ph}_{2} \mathrm{Hg}$ (DMSO- $d_{6}$ solution) at -808.5 ppm . Diastereoisomeric ratios for $\mathbf{2 2 b}$ and $\mathbf{2 4 b}$ were determined by ${ }^{2} \mathrm{H}$ NMR ( 61.4 MHz ); spectra were recorded for $\mathrm{CHCl}_{3}$ solutions (no lock, ${ }^{1} \mathrm{H}$ broad-band decoupling, 1-s acquisition time, spectral width 1000 Hz , 1000 transients). The areas for the partially overlapping signals of diastereoisomeric deuterons were determined by deconvolution (Lorenzian line-shape). The ${ }^{1} J_{\mathrm{C}-\mathrm{H}}$ values were determined from $\mathrm{f}_{2}$ traces of HMQC spectra. ${ }^{18 \mathrm{a}}$ Standard software supplied by the manufacturer was used throughout. The IR spectra were recorded in $\mathrm{CHCl}_{3}$ on a Perkin-Elmer 621 instrument. The mass spectra was measured on a Jeol JMS D-100 spectrometer using direct inlet and the lowest temperature enabling evaporation. All reactions were carried out under nitrogen. Standard workup of an ethereal solution means washing with $5 \% \mathrm{HCl}$ (aqueous), water, and $5 \% \mathrm{KHCO}_{3}$ (aqueous) and drying with $\mathrm{MgSO}_{4}$. Petroleum ether refers to the fraction boiling in the range $40-60^{\circ} \mathrm{C}$. The identity of samples prepared by different routes was checked by TLC and IR and NMR spectra. Yields are given for isolated product showing one spot on a chromatographic plate and no impurities detectable in the NMR spectrum.

3 $\beta$-((Bromomercurio)methyl)-A,B-dinor- $5 \beta$-cholestane-5-carbaldehyde (3a). To a solution of cyclopropyl alcohol 1a ( $200 \mathrm{mg} ; \mathbf{0 . 5 2 \mathrm { mmol } \text { ) } ) ~ ( 2 )}$ in DME ( 8 mL ) were added dropwise acetonitrile ( 20 mL ) and then mercury nitrate monohydrate ( $190 \mathrm{mg} ; 0.55 \mathrm{mmol}$ ). The resulting mixture was stirred at rt for 1 h , while monitored by TLC. The mixture was then quenched with aqueous KBr and diluted with ether ( 40 mL ), and the solution was washed with $5 \%$ aqueous $\mathrm{KHCO}_{3}(2 \times 10 \mathrm{~mL})$ and water ( $1 \times 20 \mathrm{~mL}$ ), dried with $\mathrm{MgSO}_{4}$, and evaporated. The residue contained pure product 3a ( 325 mg ; $97 \%$ ), showing one spot on TLC: mp 149-151 ${ }^{\circ} \mathrm{C}(\mathrm{EtOH}) ;[\alpha]_{\mathrm{D}}-9.9^{\circ}\left(c, 3.9\right.$ in $\left.\mathrm{CHCl}_{3} / \mathrm{EtOH}_{3: 2}\right)$; IR $\left(\mathrm{CHCl}_{3}\right) \nu$ (CHO) 1703 and $2706 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR $\delta 0.61(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 0.860(\mathrm{~d}$, $3 \mathrm{H}, J=6.5 \mathrm{~Hz}, 26-\mathrm{H}$ or $27-\mathrm{H}), 0.865(\mathrm{~d}, 3 \mathrm{H}, J=6.5 \mathrm{~Hz}, 26-\mathrm{H}$ or $27-\mathrm{H}), 0.90(7 \alpha-\mathrm{H}), 0.91(\mathrm{~d}, 3 \mathrm{H}, J=6.5 \mathrm{~Hz}, 21-\mathrm{H}), 0.95(\mathrm{~s}, 3 \mathrm{H}, 19-\mathrm{H})$, $1.09(17-\mathrm{H}), 1.10(14-\mathrm{H}), 1.11(9-\mathrm{H}), 1.27(11-\mathrm{H}), 1.50(25-\mathrm{H}), 1.55$ $(12-\mathrm{H}), 1.60(8-\mathrm{H}), 1.85(11-\mathrm{H}), 1.93\left(\mathrm{dd}, 1 \mathrm{H}, J_{\mathrm{gem}}=11.7 \mathrm{~Hz}, J_{3 a \mathrm{H}, 4 \mathrm{H}}\right.$ $=8.5 \mathrm{~Hz}$, pro-S-4-H), $2.05\left(\mathrm{~m}, 2 \mathrm{H}, 12-\mathrm{H}\right.$ and pro-R-4-H, $J_{\mathrm{gem}}=11.7$ $\left.\mathrm{Hz}, J_{4-\mathrm{H}, 3 \alpha \cdot \mathrm{H}}=8.1 \mathrm{~Hz}\right), 2.37(\mathrm{~m}, 1 \mathrm{H}, 3 \alpha-\mathrm{H}), 2.47\left(\mathrm{dd}, J_{7_{\alpha-\mathrm{H}, 7 \beta-\mathrm{H}}}=12.0\right.$ $\left.\mathrm{Hz}, J_{7 \beta \cdot \mathrm{H}, 88 \cdot \mathrm{H}}=6.9 \mathrm{~Hz}, 7 \beta-\mathrm{H}\right), 9.72(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CHO})$ ) ${ }^{13} \mathrm{C}$ NMR ( 75.4 MHz ) $\delta 12.20$ (C-18), 18.74 (C-21), 19.68 (C-19), 21.10 (t), 22.54 (C26 or C-27), 22.80 (C-26 or C-27), 23.86 ( t ), 24.37 ( t ), 27.99 (C-25), 28.46 (C-11), 34.78 (C-4), 35.63 (C-20), 36.20 (C-22), 36.93 (C-7), 38.88 (C-2), 39.40 (C-1), 39.46 (C-12 and C-24), 43.71 (C-13), 44.39 (C-8), 53.01 (C-3), 55.70 (C-17), 56.74 (C-14), 58.29 (C-10), 59.19 (C-9), 70.59 (C-5), 206.22 (C-6); ${ }^{199} \mathrm{Hg}$ NMR ( 53.6 MHz ) $\delta-1063$. NOE difference experiments: Irradiation of CHO resulted in the increase of $4-\mathrm{H}(1 \%), 4-\mathrm{H}^{\prime}(3 \%), 7 \beta-\mathrm{H}(1 \%)$, and $19-\mathrm{H}(3 \%)$. Irradiation of $7 \beta-\mathrm{H}$ resulted in the increase of $\mathrm{CHO}(4 \%)$ and $7 \alpha-\mathrm{H}(22 \%)$. Irradiation of $3 \alpha-\mathrm{H}$ gave an increase of $\mathrm{CHO}(1 \%), 4-\mathrm{H}(4 \%)$, and $4-\mathrm{H}^{\prime}(4 \%)$. Anal. Calcd for $\mathrm{C}_{27} \mathrm{H}_{45} \mathrm{BrHgO}: \mathrm{C}, 48.68 ; \mathrm{H}, 6.81 ; \mathrm{Br}, 12.00 ; \mathrm{Hg}, 30.11$. Found: C, 48.33; H, 7.16.
[ $\left.4^{\mathbf{2}} \mathrm{H}\right] \mathbf{3} \beta$-( (Bromomercurio)methyl)-A,B-dinor- $5 \beta$-cholestane- 5 -carbaldehyde (3b): mp 148-150 ${ }^{\circ} \mathrm{C}$; ${ }^{\text {l }} \mathrm{H}$ NMR $\delta 0.63$ (s, $3 \mathrm{H}, 18-\mathrm{H}$ ), 1.96 ( $\mathrm{d}, J=8.7 \mathrm{~Hz}, 1-\mathrm{H}, 4-\mathrm{H}$ ), $9.75\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CH}=\mathrm{O}\right.$ ); ${ }^{13} \mathrm{C}$ NMR $\delta 12.17$ (q), 18.71 (q), 19.65 (q), 21.07 (t), 22.52 (q), 22.77 (q), 23.82 (t), $24.35(\mathrm{t})$, 27.92 (d), 28.42 (t), 35.57 (d), 36.15 (t), 36.77 (t), 38.76 (t), 39.34 (t), 39.40 ( $2 \times$ t $), 43.64$ (s), 44.26 (d), 52.89 (d), 55.63 (d), 56.65 (d), 58.22 (s), 59.09 (d), 70.55 (s), 206.24 (d).

Lactol (4a). Method A. To a solution of 1a ( $410 \mathrm{mg} ; 1.06 \mathrm{mmol}$ ) in dioxane ( 12 mL ) and water ( 1 mL ) were added $10 \%$ aqueous $\mathrm{HClO}_{4}$ ( 2 mL ) and thallium nitrate trihydrate ( $570 \mathrm{mg} ; 1.28 \mathrm{mmol}$ ), and the mixture was stirred at rt for 24 h . The mixture was then diluted with ether and filtered, and the filtrate was worked up. The residue was chromatographed on silica gel ( $\mathbf{2 5 \mathrm { g } \text { ) using a petroleum ether-ether mixture (98:2) to remove }}$ impurities and then with a $90: 10$ mixture to afford lactol $4 a$ ( 269 mg , 63\%): mp 155-157 ${ }^{\circ} \mathrm{C}$ (aqueous acetone); IR $\left(\mathrm{CHCl}_{3}\right) \nu(\mathrm{OH}) 3395$, $3620 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 0.63(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 0.92(\mathrm{~s}$, $3 \mathrm{H}, 19-\mathrm{H}), 2.40(\mathrm{~m}, 1 \mathrm{H}, 3 \alpha-\mathrm{H}), 3.40\left(\mathrm{dd}, 1 \mathrm{H}, J_{\mathrm{gem}}=8.6 \mathrm{~Hz}, J_{3 \alpha \cdot \mathrm{H}, 4 \beta-\mathrm{H}}\right.$ $=4.9 \mathrm{~Hz}, 4 \beta-\mathrm{H}), 4.17\left(\mathrm{dd}, 1 \mathrm{H}, J_{\mathrm{gem}}=8.6 \mathrm{~Hz}, J_{3 \alpha \cdot \mathrm{H}, 4 \alpha-\mathrm{H}}=9.1 \mathrm{~Hz}\right.$, $4 \alpha-\mathrm{H}), 5.17(\mathrm{~s}, 1 \mathrm{H}, 6 \beta-\mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $75.4 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 12.21$ (q), 18.53 (q), 18.75 (q), 22.18 (t), 22.54 (q), 22.79 (q), 23.82 (t), 24.48 ( $)$, 27.98 (d), 28.44 (t), 28.56 (t), 35.64 (d), 36.10 (t), 36.21 (t), 37.87 (t), 39.47 (t), 39.73 (t), 40.92 (d), 43.66 (s), 49.24 (d), 53.02 (s), 55.04 (d), 55.67 (d), 56.56 (d), 65.44 (s), 71.91 (t), 101.16 (d); HRMS (EI, 70 eV ) $\mathrm{m} / \mathrm{z}$ (relative intensity) $402\left(26, \mathrm{M}^{+}\right), 385\left(17, \mathrm{M}^{+}-\mathrm{OH}\right), 384\left(21, \mathrm{M}^{+}\right.$ $\left.-\mathrm{H}_{2} \mathrm{O}\right), 358\left(21, \mathrm{M}^{+}-\mathrm{CO}_{2}\right), 356\left(58, \mathrm{C}_{26} \mathrm{H}_{44}\right)$. The configuration of hydroxyl was established by ${ }^{1} \mathrm{H}$ NMR, as an appreciable NOE (ca. 8\%) can be seen for the acetal proton upon irradiation of the angular methyl. Anal. Calcd for $\mathrm{C}_{27} \mathrm{H}_{46} \mathrm{O}_{2}$ : $\mathrm{C}, 80.54 ; \mathrm{H}, 11.51$. Found: $\mathrm{C}, 80.21 ; \mathrm{H}$, 11.72.

Method B. To a solution of lithium chloride ( 30 mg ; 5 equiv) in DME ( 3 mL ) was added palladium(II) chloride ( $1.5 \mathrm{mg} ; 5 \mathrm{~mol} \%$ ), and the mixture was stirred at rt for 15 min . Copper(II) chloride ( $100 \mathrm{mg} ; 5$ equiv) was then added, and the mixture was stirred for an additional 15 min . Then a solution of organomercurial 3a ( $100 \mathrm{mg} ; 0.15 \mathrm{mmol}$ ) in DME ( 2 mL ) was added, and the mixture was stirred at rt. The reaction reached completion after 12 h (TLC). The mixture was then diluted with ether ( 20 mL ), washed with water $\left(6 \times 10 \mathrm{~mL}\right.$ ), $5 \%$ aqueous $\mathrm{KHCO}_{3}$ $(1 \times 10 \mathrm{~mL})$, and water ( $1 \times 10 \mathrm{~mL}$ ), and dried with $\mathrm{MgSO}_{4}$. The solvent was evaporated, and the residue was chromatographed on a column of silica gel, using a petroleum ether-ether mixture (9:1) as eluent to give lactol da ( $56 \mathrm{mg} ; 93 \%$ ), identical with an authentic sample: $\mathrm{mp} 156-158$ ${ }^{\circ} \mathrm{C}$.

Deuterated lactol (4b): mp $152-154^{\circ} \mathrm{C}$ (aqueous acetone); ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 0.63(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 0.88(\mathrm{~s}, 3 \mathrm{H}, 19-\mathrm{H}), 4.15(\mathrm{~d}$, $\left.1 \mathrm{H}, J_{3 \alpha \cdot \mathrm{H}, 4 \alpha \cdot \mathrm{H}}=9.2 \mathrm{~Hz}, 4 \alpha-\mathrm{H}\right), 5.17(\mathrm{~s}, 1 \mathrm{H}, 6 \beta-\mathrm{H})$; in NOE difference experiments, irradiation at $4.15(4 \alpha-\mathrm{H})$ gave $11 \%$ enhancement of the signal at $2.39(3 \alpha-H)$, while irradiation at 2.39 resulted in $17 \%$ enhancement of the signal at $4.15(4 \alpha-H)$; no enhancement of the latter signal was detected upon irradiation at $5.17(6 \beta-H) ;{ }^{13} \mathrm{C}$ NMR (75.4 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 12.27(\mathrm{q}), 18.53(\mathrm{q}), 18.76(\mathrm{q}), 22.20(\mathrm{t}), 22.52(\mathrm{q})$, 22.86 (q), 23.83 (t), 24.49 ( $t), 27.99$ (d), 28.40 (t), 28.57 (t), 35.66 (d), 36.10 (t), 36.22 (t), 37.89 (t), 39.48 (t), 39.74 (t), 40.94 (d), 43.68 ( s$)$, 49.15 (d), 53.04 (s), 55.09 (d), 55.68 (d), 56.58 (d), 65.49 (s), 101.20 (d); LRMS $m / z 403\left(\mathrm{M}^{+}\right)$.

Methyl acetal (5a) was prepared from 3a in the same way as lactol 4 a , using $\mathrm{PdCl}_{2}, \mathrm{CuCl}_{2}$, and LiCl in a mixture of DME and methanol ( $1: 1$ ) as a solvent: $\mathrm{mp} 75-76^{\circ} \mathrm{C}$ (dec; $\mathrm{CHCl}_{3}$-acetone); ${ }^{1} \mathrm{H}$ NMR $\delta(300$ $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 0.64(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 0.88(\mathrm{~s}, 3 \mathrm{H}, 19-\mathrm{H}), 0.91(\mathrm{~d}, 3 \mathrm{H}$, $J=7 \mathrm{~Hz}, 21-\mathrm{H}), 1.80(\mathrm{~m}, 2 \mathrm{H}, 2 \alpha-\mathrm{H}$ and $2 \beta-\mathrm{H}), 2.01$ (ddd, $1 \mathrm{H}, J_{\mathrm{gem}}$ $\left.=12.5 \mathrm{~Hz}, J_{11 \alpha \cdot \mathrm{H}, 12 \beta \cdot \mathrm{H}}=6.5, J_{11 \beta \cdot \mathrm{H}, 12 \beta \cdot \mathrm{H}}=6.5 \mathrm{~Hz}, 12 \beta-\mathrm{H}\right), 2.24$ (dd, $\left.1 \mathrm{H}, J_{\text {gem }}=12.9 \mathrm{~Hz}, J_{7 \beta-\mathrm{H}, 8 \beta-\mathrm{H}}=6.0,7 \beta-\mathrm{H}\right), 2.31(\mathrm{~m}, 1 \mathrm{H}, 3 \alpha-\mathrm{H}), 3.32$ $\left(\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{O}\right), 3.37\left(\mathrm{dd}, 1 \mathrm{H}, J_{\mathrm{gem}}=8.5 \mathrm{~Hz}, J_{3 \alpha \cdot \mathrm{H}, 4 \beta \cdot \mathrm{H}}=4.4 \mathrm{~Hz}, 4 \beta-\mathrm{H}\right)$, $3.98\left(\mathrm{dd}, J_{\mathrm{gem}}=8.5 \mathrm{~Hz}, J_{3 \alpha-\mathrm{H}, 4 \alpha \cdot \mathrm{H}}=9.1 \mathrm{~Hz}, 4 \alpha-\mathrm{H}\right), 4.60(\mathrm{~s}, 1 \mathrm{H}, 6 \beta-\mathrm{H})$; ${ }^{13} \mathrm{C}$ NMR $\delta\left(75.4 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 12.27(\mathrm{q}, \mathrm{C}-18), 18.50(\mathrm{q}, \mathrm{C}-19)$, 18.78 ( $\mathrm{q}, \mathrm{C}-21$ ), 22.23 (t, C-11), 22.57 ( $\mathrm{q}, \mathrm{C}-26$ ), 22.82 ( $\mathrm{q}, \mathrm{C}-27$ ), 23.85 (t, C-16), 24.52 (t, C-15), 28.02 (d, C-25), 28.60 (t, C-2), 28.79 ( $t$, C-23), 35.68 (d, C-20), 36.10 (t, C-1), 36.24 (t, C-22), 37.31 (t, C-7), 39.51 (t, C-24), 39.79 (t, C-12), 40.93 (d, C-8), 43.71 (s, C-13), 49.88 (d, C-3), 53.18 (s, C-10), $54.05\left(\mathrm{q}, \mathrm{CH}_{3} \mathrm{O}\right), 54.90(\mathrm{~d}, \mathrm{C}-9), 55.70(\mathrm{~d}$, C-17), 56.68 (d, C-14), 65.99 (s, C-5), 71.75 (t, C-4), 107.61 (d, C-6) (the three $\mathrm{CH}_{2}$ carbons at $23.85,24.52$, and 28.79 were assigned tentatively and can be interchanged); HRMS (EI, 70 eV ) $\mathrm{m} / \mathrm{z}$ (relative intensity) $416\left(0.2 \mathrm{M}^{+}\right), 385\left(15, \mathrm{M}^{+}-\mathrm{CH}_{3} \mathrm{O}\right), 356\left(100, \mathrm{C}_{26} \mathrm{H}_{44}\right)$. 3-Methylidene-A-nor-5 $\beta$-cholestan-5-ol (12). A mixture of 7 (140 $\mathrm{mg} ; 0.38 \mathrm{mmol}$ ), thallium nitrate trihydrate ( $230 \mathrm{mg} ; 0.52 \mathrm{mmol}$ ), and aqueous $10 \%$ perchloric acid ( 0.4 mL ) in dioxane ( 8 mL ) was stirred at rt for 4 h . The mixture was diluted with ether, the precipitate was filtered off, and the organic phase was worked up as usual. The crude product was chromatographed on silica ( 10 g ) using hexane, which eluted lipophilic impurities, followed by hexane-ether ( $97: 3$ ) mixture to yield 12 ( 38 mg ; $26 \%$ ): $\mathrm{mp} 56-58{ }^{\circ} \mathrm{C}$ (aqueous acetone; lit. ${ }^{37}$ gives $58^{\circ} \mathrm{C}$ ); $[\alpha]_{\mathrm{D}}+21^{\circ}(\mathrm{c}$ 2.0; lit. ${ }^{37}$ gives $+20^{\circ}$ ); ${ }^{1} \mathrm{H}$ NMR $\delta 0.68(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 1.01(\mathrm{~s}, 3 \mathrm{H}$, $19-\mathrm{H}), 1.35(\mathrm{~m}, 1 \mathrm{H}, 1-\mathrm{H}), 1.65(\mathrm{~m}, 2 \mathrm{H}, 1-\mathrm{H}$ and $6-\mathrm{H}), 1.91(\mathrm{~m}, 1 \mathrm{H}$, $6-\mathrm{H}), 1.96(\mathrm{~m}, 1 \mathrm{H}, 12-\mathrm{H}), 2.30(\mathrm{~m}, 2 \mathrm{H}, 2-\mathrm{H}), 2.45(\mathrm{~m}, 2 \mathrm{H}, 2-\mathrm{H}), 4.99$ (dd, $J=2.2$ and $2.2 \mathrm{~Hz}, 1 \mathrm{H}, 4 E-\mathrm{H}$ ), 5.07 (dd, $J=2.5$ and $2.5 \mathrm{~Hz}, 1$ $\mathrm{H}, 4 Z-\mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta 12.01$ (q), 13.75 (q), 18.63 (q), 22.27 (t), 22.54 (q), 22.73 (q), 23.79 (t), 24.18 (t), 27.15 (t), 27.99 (d), 28.84 (t), 28.85 (t), 29.97 (t), 31.08 (t), 34.96 (d), 35.75 (d), 36.12 (t), 39.48 (t), 40.02 (t), 42.53 (s), 45.08 (d), 48.28 (s), 56.15 (d), 56.40 (d), 81.44 (s), 107.33 (t), 155.19 (s).

3 $\alpha, 5$-Cyclo-5 $\alpha$-cholest-6-ene (13). A solution of $3 \alpha, 5$-cyclo-5 $\alpha$-cholest6 -one ${ }^{15.76}(1.50 \mathrm{~g} ; 3.9 \mathrm{mmol})$ and tosylhydrazine ( $850 \mathrm{mg} ; 4.3 \mathrm{mmol} ; 1.1$ equiv) in methanol ( 30 mL ) was refluxed for 5 min and then cooled to rt , and the crystalline tosylhydrazone ( $1.85 \mathrm{~g} ; 86 \%$ ) was isolated by suction: mp 203-25 ${ }^{\circ} \mathrm{C}$ (dec) (methanol). The crude tosylhydrazone $(1.85 \mathrm{~g} ; 3.4 \mathrm{mmol})$ was dissolved in ether ( 30 mL ) and cooled to $-30^{\circ} \mathrm{C}$, and to this solution was added 1.4 M methyllithium ( $10 \mathrm{~mL} ; 14 \mathrm{mmol}$; 4.12 equiv). The mixture was stirred and allowed to warm slowly to rt. The reaction was complete after 2 h (as revealed by TLC). The mixture was decomposed by saturated aqueous $\mathrm{NH}_{4} \mathrm{Cl}$ and diluted with ether, and the ethereal solution was worked up to afford $13(1.20 \mathrm{~g} ; 96 \%)$ : mp $71-72^{\circ} \mathrm{C}\left(\right.$ lit. ${ }^{77}$ gives $\left.73^{\circ} \mathrm{C}\right) ;[\alpha]_{\mathrm{D}}-48^{\circ}\left(\mathrm{c} 1.4\right.$; lit. ${ }^{77}$ gives $\left.-47.2^{\circ}\right)$; IR $\nu(\mathrm{C}=\mathrm{C}) 1640, \nu(\mathrm{C}=\mathrm{CH}) 3020, \nu\left(\mathrm{C}-\mathrm{H}\right.$ cycloprop) $3060 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.46$ and 0.48 ( AB system, $J=5.1 \mathrm{~Hz}, 2 \mathrm{H}, 4 \alpha-\mathrm{H}$ and $4 \beta-\mathrm{H}$ ), 0.75 ( s , $3 \mathrm{H}, 18-\mathrm{H}), 0.93(\mathrm{~s}, 3 \mathrm{H}, 19-\mathrm{H}), 5.24\left(\mathrm{dd}, J_{6-\mathrm{H}, 7 \cdot \mathrm{H}}=9.8 \mathrm{~Hz}, J_{7 \cdot \mathrm{H}, 8 \beta-\mathrm{H}}\right.$ $=2.5 \mathrm{~Hz}, 1 \mathrm{H}, 7-\mathrm{H}), 5.57\left(\mathrm{dd}, J_{6-\mathrm{H}, 7 \mathrm{H}}=9.8 \mathrm{~Hz}, J_{6-\mathrm{H}, 88-\mathrm{H}}=1.5 \mathrm{~Hz}, 1\right.$ $\mathrm{H}, 6-\mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta 12.01$ (q), 14.49 (t), 17.68 (q), 18.53 (q), 22.16 (t), 22.43 (q), 22.68 (q), 23.78 (t), 24.03 (t), 25.00 (t), 25.63 (d), 27.86 (d), 28.28 (t), 31.35 (t), 35.70 (d), 36.03 (t), 36.36 (d), 36.53 (s), 39.36 (t), 40.15 (t), 42.38 (s), 43.20 (s), 45.93 (d), 54.84 (d), 56.04 (d), 127.42 (d), 131.46 (d).

Palladium Complex (15). A mixture of olefin 13 ( $110 \mathrm{mg} ; 0.30 \mathrm{mmol}$ ), $(\mathrm{MeCN})_{2} \mathrm{PdCl}_{2}(80 \mathrm{mg} ; 0.31 \mathrm{mmol})$, and $\mathrm{CuCl}_{2}(10 \mathrm{mg} ; 0.07 \mathrm{mmol})$ in methanol ( 30 mL ) was stirred at rt for 20 h under nitrogen and with exclusion of light. The solvent was then evaporated in vacuo, the residue was dissolved in petroleum ether, and the solution was filtered through a pad of aluminum oxide. First, impurities were eluted with a petroleum ether-benzene mixture ( $1: 1$ ). Elution with chloroform furnished a crude product ( 180 mg ), which was chromatographed on silica gel ( 10 g ) with a petroleum ether-ether-acetone mixture (89:10:1) to afford 15 (136 $\mathrm{mg} ; 93 \%$ ); recrystallization from a benzene-methanol mixture gave pure yellow crystals of $15(97 \mathrm{mg}): \mathrm{mp} 106-108^{\circ} \mathrm{C}(\mathrm{dec}) ;[\alpha]_{\mathrm{D}}-80^{\circ}(c 2.1)$; ${ }^{1} \mathrm{H}$ NMR $0.66(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 3.36\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{O}\right), 3.96(\mathrm{~m}, W / 2=22$ $\mathrm{Hz}, 3 \alpha-\mathrm{H}), 4.64$ and $5.19\left(\mathrm{AB}\right.$ system, $J_{6-\mathrm{H}, 7 \mathrm{H}}=8 \mathrm{~Hz}, 2 \mathrm{H}, 6-\mathrm{H}$ and 7-H). Anal. Calcd for $\mathrm{C}_{36} \mathrm{H}_{94} \mathrm{Cl}_{2} \mathrm{O}_{2} \mathrm{Pd}_{2}$ : $\mathrm{C}, 62.09 ; \mathrm{H}, 8.76$. Found: C , 61.85; H, 8.80.
[ $\left.7 \alpha-{ }^{2} \mathrm{H}\right]$-3 $\beta$-Methoxycholest-5-ene (16). To a solution of 15 (80 mg; 0.08 mmol ) in ether ( 5 mL ) was added lithium aluminum deuteride ( 20 $\mathrm{mg} ; 0.48 \mathrm{mmol}$ ) at $-78^{\circ} \mathrm{C}$, and the mixture was stirred at this temperature for 15 min . The excess of reagent was decomposed with water, the mixture was diluted with ether and water, and the organic layer was worked up. The residue was purified by chromatography on a silica gel plate ( $20 \times$ 20 cm ) using a petroleum ether-ether mixture ( $95: 5$ ) to give 16 ( 35 mg ; $53 \%$ ), identical (TLC) with an authentic sample of the unlabeled

[^10]compound: $\mathrm{mp} 83-84^{\circ} \mathrm{C}$ (lit. ${ }^{78}$ gives $83.7-84.4^{\circ} \mathrm{C}$ ); $[\alpha]_{\mathrm{D}}-40^{\circ}(\mathrm{c} 1.9)$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.68(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 2.16(\mathrm{~m}, W=29 \mathrm{~Hz}, 1 \mathrm{H}, 4 \beta-\mathrm{H}), 2.93$ $(\mathrm{m}, W=20 \mathrm{~Hz}, 1 \mathrm{H}, 4 \alpha-\mathrm{H}), 3.06(\mathrm{~m}, W=32 \mathrm{~Hz}, 3 \alpha-\mathrm{H}) ; 3.35(\mathrm{~s}, 3 \mathrm{H}$, $\left.\mathrm{OCH}_{3}\right), 5.35\left(\mathrm{dd}, J_{6-\mathrm{H}, 7 \alpha \mathrm{H}}=5.4, J_{6-\mathrm{H}, 4 \alpha-\mathrm{H}}=1.9 \mathrm{~Hz}, 1-\mathrm{H}, 6-\mathrm{H}\right) ; \mathrm{HRMS}$ $m / z 401\left(\mathrm{M}^{\cdot+}, \mathrm{C}_{28} \mathrm{H}_{47} \mathrm{DO}\right), 386,369,354,330,302,275,256,242,228$, $199,185,161,149,129,111,97,83,71,57,43$.
(19S)-[192H]-Cholest-5-eme-3 $\beta$,19-diol 3-Monoacetate (18b). To a solution of lithium aluminum deuteride ( $280 \mathrm{mg} ; 7.38 \mathrm{mmol}$ ) in ether ( 70 mL ) was added dropwise tert-butyl alcohol ( $1.64 \mathrm{~g} ; 22.13 \mathrm{mmol}$ ) in ether ( 5 mL ) at $-78^{\circ} \mathrm{C}$. The mixture was stirred at $-10^{\circ} \mathrm{C}$ for 30 min under argon and then cooled to $-78^{\circ} \mathrm{C}$. A solution of aldehyde 17 ( 300 mg ; $0.68 \mathrm{mmol})$ in ether ( 10 mL ) was added, and the mixture was stirred at $-78^{\circ} \mathrm{C}$ for 20 min while monitored by TLC. The excess of reagent was decomposed by saturated $\mathrm{NH}_{4} \mathrm{Cl}$ (aqueous), and the mixture was diluted by ether and worked up to afford $\mathbf{1 8 b}$ ( $290 \mathrm{mg} ; 96 \%$ ): ${ }^{1} \mathrm{H}$ NMR $\delta 0.72$ ( $\mathrm{s}, 3 \mathrm{H}, 18-\mathrm{H}$ ), $1.99\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{CO}_{2}\right), 3.56(\mathrm{~s}, 0.17 \mathrm{H}, 19-\mathrm{H}), 3.78(\mathrm{~s}$, $0.85 \mathrm{H}, 19-\mathrm{H}), 4.62(\mathrm{~m}, W=27.4 \mathrm{~Hz}, 1 \mathrm{H}, 3 \alpha-\mathrm{H}), 5.71(\mathrm{~d}, J=4.6 \mathrm{~Hz}$, $1 \mathrm{H}, 6-\mathrm{H})$.
(19S)-[19²H]-Cholest-5-ene-38,19-diol 3-Acetate 19-Mesylate (19b). To a solution of the alcohol 18 b ( $290 \mathrm{mg} ; 0.65 \mathrm{mmol}$ ) and triethylamine ( 0.1 mL ) in THF ( 60 mL ) was added mesyl chloride ( 0.8 mL ) at -10 ${ }^{\circ} \mathrm{C}$, and the mixture was kept at this temperature for 1 h . The mixture was then poured on ice and water, the product was extracted with ether, and the ethereal solution was worked up to yield mesylate 19b ( 330 mg , $97 \%$ ), identical (TLC) with its unlabeled counterpart (19a);42 this product was directly used in the next procedure without further purification.
(19R)-[192 H$]-5,19$-Cyclo- $5 \beta$-cholestan-3 $\beta$-ol (20b). The mesylate 19b ( $270 \mathrm{mg} ; 0.52 \mathrm{mmol}$ ) in ether ( 100 mL ) was treated with lithium aluminum hydride ( $250 \mathrm{mg} ; 6.51 \mathrm{mmol}$ ) at rt for 28 h . The mixture was then cooled to $-78^{\circ} \mathrm{C}$, the excess of reagent was decomposed with saturated $\mathrm{NH}_{4} \mathrm{Cl}$ (aqueous), the product was extracted with ether, and the ethereal solution was worked up. The crude product was chromatographed on silica gel $(15 \mathrm{~g})$ with a petroleum ether-ether mixture (8:2) to afford 20 b ( 176 mg ; $88 \%$ ), identical (TLC) with its unlabeled counterpart (20a). ${ }^{42}$

5,19-Cyclo- $5 \beta$-cholestan-3-one (21a). Method A. The alcohol ${ }^{42}$ 20a ( $750 \mathrm{mg} ; 1.94 \mathrm{mmol}$ ) was dissolved in acetone-DME mixture ( $1: 1 ; 50$ mL ) and oxidized with Jones' reagent at $0^{\circ} \mathrm{C}$ for 10 min . The excess of reagent was decomposed with methanol, the mixture was diluted with ether and water, and the product was extracted with ether. The ethereal solution was successively washed with saturated aqueous $\mathrm{KHCO}_{3}$ ( $3 \times$ 30 mL ) and water and dried with $\mathrm{MgSO}_{4}$. Ether was evaporated, and the residue was chromatographed on silica ( 30 g ) using a petroleum ether-ether mixture (95:5) as eluent to yield 21a ( $710 \mathrm{mg} ; 95 \%$ ): mp $96-98^{\circ} \mathrm{C}$ (acetone); $[\alpha]_{\mathrm{D}}+47^{\circ}(c 1.7)$; IR $\nu(\mathrm{C}=0) 1705 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.47(\mathrm{~d}, J=5.7 \mathrm{~Hz}, 1 \mathrm{H}, 19-\mathrm{H}), 0.51(\mathrm{~d}, J=5.7 \mathrm{~Hz}, 1 \mathrm{H}, 19-\mathrm{H})$, $0.70(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 2.51$ and $2.57\left(\mathrm{AB}\right.$ system, $J_{\mathrm{gem}}=18.1 \mathrm{~Hz}, 2 \mathrm{H}, 4 \alpha-\mathrm{H}$ and $4 \beta-\mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta 12.13$ (q), 17.53 (t, C-19), 18.32 (s), 18.54 (q), 22.43 (q), 22.68 (q), 23.68 (t), 23.93 (t), 25.11 (s), 25.35 (t), 26.38 (t), 27.24 (t), 27.86 (d), 28.10 (t), 31.74 (t), 35.53 (d), 35.60 (d), 36.00 (t), 36.08 (t), 39.35 (t), 39.85 (t), 42.97 (s), 46.44 (d), 48.28 (t), 54.99 (d), 56.28 (d), 212.55 (s). Anal. Calcd for $\mathrm{C}_{27} \mathrm{H}_{44} \mathrm{O}: \mathrm{C}, 84.31 ; \mathrm{H}, 11.53$. Found: C, 84.17; H, 11.75.

Method B. To a stirred suspension of copper(I) iodide ( $270 \mathrm{mg} ; 1.42$ mmol) in dry DME ( 5 mL ) was added dropwise a 1.4 M solution of methyllithium in ether ( $2 \mathrm{~mL} ; 2.8 \mathrm{mmol}$ ) at $-78^{\circ} \mathrm{C}$. The mixture was stirred under nitrogen at $-10^{\circ} \mathrm{C}$ for 10 min and then cooled to $-78^{\circ} \mathrm{C}$. At this temperature, a precooled $\left(-20^{\circ} \mathrm{C}\right)$ solution of the organomercurial 22a ( $80 \mathrm{mg} ; 0.12 \mathrm{mmol}$ ) in DME ( 1 mL ) was added. The mixture was stirred at $-78^{\circ} \mathrm{C}$ for 5 min and then quenched with water. The product was extracted with ether, and the ethereal solution was worked up. The crude product was chromatographed on silica ( 5 g ) using a petroleum ether-ether mixture (95:5) as eluent to give pure 21a ( $40 \mathrm{mg} ; 86 \%$ ): mp $98-99^{\circ} \mathrm{C}$.

Method C. The organomercurial 22a ( 100 mg ) was treated with aluminum chloride ( 40 mg ) in dry DME ( 5 mL ) at rt for 12 h and monitored by TLC. The mixture was then cooled to $-20^{\circ} \mathrm{C}$, water ( 1 mL ) was added dropwise, and the mixture was allowed to warm to rt. The mixture was extracted with ether, and the ethereal solution was worked up. Chromatography on silica ( 5 g ) with a petroleum etherether mixture ( $95: 5$ ) yielded 21 a ( $54 \mathrm{mg} ; 93 \%$ ): $\mathrm{mp} 95-96^{\circ} \mathrm{C}$.
(19R)-[19² H$]-5,19$-Cyclo-5 $\beta$-cholestan-3-one (21b): $\mathrm{mp} 86-87^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.47$ (s, $\left.0.84 \mathrm{H}, 19-\mathrm{H}\right), 0.71$ (s, $\left.3 \mathrm{H}, 18-\mathrm{H}\right)$.

19-(Bromomercurio) cholest-4-en-3-one (22a). The third fraction after isolation of 24a and 25a contained 22a ( $543 \mathrm{mg} ; 35 \%$ ): mp $117-120^{\circ} \mathrm{C}$

5-Methyl-19-norcholest-9-en-3-one (26). A solution of 25a ( 40 mg ; 0.060 mmol ) in benzene ( 5 mL ) was refluxed with a 1 M benzene solution of tributyltin hydride ( 0.3 mL ) and a catalytic amount of $2,2^{\prime}$ azoisobutyronitrile for 10 min . The mixture was then diluted with ether, washed with $5 \% \mathrm{NaF}$ (aqueous) and $5 \% \mathrm{KHCO}_{3}$ (aqueous), and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and the solvent was evaporated. The residue was chromatographed on silica gel ( 2 g ) with a petroleum ether-ether mixture ( $9: 1$ ) as eluent to give 26 ( $23 \mathrm{mg} ; 69 \%$ ), identical with an authentic sample: $4^{46}[\alpha]_{\mathrm{D}}+18^{\circ}\left(c 2.0\right.$; lit. ${ }^{46}$ gives $\left.+20^{\circ}\right)$; IR $\nu(\mathrm{C}=\mathrm{O}) 1713 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.82(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 1.03$ ( $\mathrm{s}, 3 \mathrm{H}, 5 \beta$-methyl).

38-((Methylmercurio) methyl)-A,B-dinor-5 $\beta$-cholestane-5-carbaldehyde (27). Method A. To a stirred suspension of copper(I) iodide (266
$\mathrm{mg} ; 1.40 \mathrm{mmol}$ ) in dry THF ( 10 mL ) was added dropwisea 1.4 M solution of methyllithium in THF ( 1 mL ; 1.4 mmol ) at $-35^{\circ} \mathrm{C}$. The mixture was stirred under nitrogen at the same temperature for 10 min , and then a precooled $\left(-20^{\circ} \mathrm{C}\right)$ solution of organomercurial $3 \mathrm{a}(260 \mathrm{mg} ; 0.40 \mathrm{mmol})$ in THF ( 5 mL ) was added. Since TLC indicated an instantaneous reaction, the mixture was then poured into an ice-cold aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}$, the product was extracted with ether, and the organic phase was worked up. The solvent was evaporated to give oily methylmercury $27(225 \mathrm{mg} ; 94 \%)$ showing one spot on TLC: $[\alpha]_{\mathrm{D}}-6^{\circ}(c 6.3)$; IR 1712, $2698 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR $\delta 0.32\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{Hg}\right), 0.64(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 0.96$ ( $\mathrm{s}, 3 \mathrm{H}, 19-\mathrm{H}$ ), $9.81(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CH}=\mathrm{O}) ;{ }^{13} \mathrm{C}$ NMR $\delta 12.19$ (C-18), 18.72 (C-21), $19.57(\mathrm{C}-19), 20.94\left(\mathrm{CH}_{3} \mathrm{Hg}\right), 21.07(\mathrm{t}), 22.54$ (C-26 or $\mathrm{C}-27$ ), 22.80 (C-26 or C-27), 23.85 (t), 24.37 (t), 27.98 (d), 28.49 (t), 35.63 (d), $36.20(\mathrm{t}), 36.46(\mathrm{C}-7), 39.46(\mathrm{t}), 39.58(\mathrm{t}), 39.70(\mathrm{t}), 39.90(\mathrm{t}), 42.22(\mathrm{t})$, 43.67 (C-13), 44.04 (d), 54.37 (C-3), 55.73 (d), 56.87 (d), 57.38 (C-10), 59.45 (d), 71.57 (s), $207.37(\mathrm{CH}=\mathrm{O}) ;{ }^{199} \mathrm{Hg}$ NMR $\delta$-161.6; MS (EI, $70 \mathrm{eV}) m / z 600\left(\mathrm{M}^{+}, 0.3\right), 587(0.2), 559(3), 385(100), 367(20), 341$ (24), 247 (13), 217 (33), 215 (32). Anal. Calcd for $\mathrm{C}_{28} \mathrm{H}_{48} \mathrm{HgO}: \mathrm{C}$, $55.93 ; \mathrm{H}, 8.05 ; \mathrm{Hg}, 33.36$. Found: $\mathrm{C}, 55.71 ; \mathrm{H}, 7.83$.

Method B. To a solution of 3 a ( $150 \mathrm{mg} ; 0.23 \mathrm{mmol}$ ) in ether ( 50 mL ) was added a 2 M solution of trimethylaluminum in hexane ( $0.5 \mathrm{~mL} ; 1.1$ mmol ) at $-78^{\circ} \mathrm{C}$. The mixture was stirred at the same temperature for 30 min , the excess of the reagent was then decomposed by $10 \% \mathrm{HCl}$ (aqueous) at $-78^{\circ} \mathrm{C}$, and the mixture was worked up. The crude product was dissolved in ether and was filtered through a pad of silica gel. The filtrate was evaporated to give $27(121 \mathrm{mg} ; 69 \%)$, identical with the product prepared under method A.

Method C. A 1.4 M solution of methyllithium in THF ( $2 \mathrm{~mL} ; 2.8$ mmol) was added to zinc(II) chloride ( $200 \mathrm{mg} ; 1.47 \mathrm{mmol}$ ) in THF ( 50 mL ) at $-30^{\circ} \mathrm{C}$, and the mixture was stirred at $-30^{\circ} \mathrm{C}$ for 30 min . The organomercurial 3 a ( $100 \mathrm{mg} ; 1.50 \mathrm{mmol}$ ) was then added, and the mixture was stirred at $-30^{\circ} \mathrm{C}$, then cooled to $-78^{\circ} \mathrm{C}$, and decomposed with saturated $\mathrm{NH}_{4} \mathrm{Cl}$ (aqueous). The mixture was then diluted with ether and worked up to give pure 27 ( 82 mg ; $91 \%$ ), identical with the product obtained under method A.

A-Homo-B-nor-3,5-cyclo-5 $\alpha$-cholestan-6 $\alpha$-ol (29a). To a stirred suspension of copper(I) iodide ( $260 \mathrm{mg} ; 1.40 \mathrm{mmol}$ ) in dry THF ( 20 mL ) was added dropwise a 1.4 M solution of methyllithium in THF ( 2 mL ; 2.8 mmol ) at $-78^{\circ} \mathrm{C}$. The mixture was stirred under nitrogen at $-10^{\circ} \mathrm{C}$ for 10 min and then cooled to $-78^{\circ} \mathrm{C}$. At this temperature, a precooled ( $-20^{\circ} \mathrm{C}$ ) solution of the organomercurial 3 a ( $300 \mathrm{mg} ; 0.45 \mathrm{mmol}$ ) in THF ( 5 mL ) was added. Since TLC indicated an instantaneous reaction, the mixture was then poured into an ice-cold aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}$, the product was extracted with ether, and the organic phase was worked up. The solvent was evaporated to give cyclobutanol 29a ( $159 \mathrm{mg} ; 93 \%$ ), showing one spot on TLC: mp 97-99 ${ }^{\circ} \mathrm{C}\left(\mathrm{Me}_{2} \mathrm{CO}\right)$; $[\alpha]_{\mathrm{D}}+26^{\circ}(c 5.0)$; IR $\nu(\mathrm{OH}) 3430$ and $3600 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.66(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 0.94$ ( $\mathrm{s}, 3 \mathrm{H}, 19-\mathrm{H}$ ), 2.42 (ddd, $1 \mathrm{H}, 3 \alpha-\mathrm{H}$ ), 4.19 (dd, $1 \mathrm{H}, J=4.6$ and 5.4 $\mathrm{Hz}, \mathrm{CHOH}$ ); ${ }^{13} \mathrm{C}$ NMR $\delta 12.31$ (C-18), 17.17 (C-21), 18.78 (C-19), 21.85 (t), 22.56 (C-26 or C-27), 22.81 (C-26 or C-27), 23.83 (t), 24.49 (t), 28.00 (d), 28.56 (t), 28.96 (t), 32.86 (t), 34.95 (t), 35.66 (d), 36.25 (t), 36.30 (t), 39.50 (t), 39.82 (t), 40.96 (d), 43.98 ( $\mathrm{s}, \mathrm{C}-13$ ), 45.56 (d), 53.48 (d), 53.62 (s), 55.72 (d), 57.07 (d), 63.82 (s), 68.59 (d). Anal. Calcd for $\mathrm{C}_{27} \mathrm{H}_{46} \mathrm{O}: \mathrm{C}, 83.87 ; \mathrm{H}, 11.99$. Found: C, $83.60 ; \mathrm{H}, 12.24$.

6 $\alpha$-((Ethoxycarbonyl)methyl)-A-homo-B-nor-3,5-cyclo-5 $\alpha$-cholestane (35). Method A. To a solution of 32 ( $120 \mathrm{mg} ; 0.16 \mathrm{mmol}$ ) in dry THF ( 10 mL ) was added a 2 M solution of trimethylaluminum in hexane ( $0.2 \mathrm{~mL} ; 2.5$ equiv) at $-78^{\circ} \mathrm{C}$. The mixture was stirred at this temperature for 1 h . Then a 1.6 M solution of butylithium in hexane $(0.3 \mathrm{~mL} ; 3$
equiv) was added, and the mixture was stirred at $-78^{\circ} \mathrm{C}$ for 1 h and allowed to warm to rt. The excess of reagent was decomposed by $10 \%$ aqueous $\mathbf{H C l}$, the product was extracted with ether, and the ethereal layer was worked up. The solvent was evaporated, and the residue was chromatographed on a column of silica gel with a petroleum ether-ether mixture (97:3) as eluent to give pure 35 ( $68 \mathrm{mg} ; 92 \%$ ): $[\alpha]_{\mathrm{D}}+18^{\circ}(c$ 6.8 ); IR $1728 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.65$ (s, $3 \mathrm{H}, 18-\mathrm{H}$ ), 0.96 ( $\mathrm{s}, 3 \mathrm{H}, 19-\mathrm{H}$ ), $1.28\left(\mathrm{t}, J=7.1 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}\right), 4.15\left(\mathrm{q}, 2 \mathrm{H}, J=7.1 \mathrm{~Hz}, \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}\right)$; ${ }^{13} \mathrm{C}$ NMR $\delta 12.18$ (q), 14.17 (q), 17.28 (q), 18.64 (q), 21.93 (t), 22.42 (q), 22.67 (q), 23.69 (t), 24.37 (t), 26.95 (t), 27.86 (d), 28.43 (t), 29.06 (t), 30.68 (d), 35.52 (d), 36.02 (t), 36.11 (t), 37.46 ( t), 39.36 (two t), 39.76 (t), 40.90 (d), 43.82 (s), 46.53 (d), 52.84 (d), 54.09 (s), 55.57 (d), 56.90 (d), 59.93 (t), 60.21 (s), 173.20 (s). Anal. Calcd for $\mathrm{C}_{31} \mathrm{H}_{52} \mathrm{O}_{2}$ : C, 81.52; H, 11.48. Found: C, 81.33; H, 11.21 .

Method B. To a stirred suspension of copper(I) iodide ( $260 \mathrm{mg} ; 1.40$ mmol ) in dry THF ( 5 mL ) was added dropwise a 1.4 M solution of methyllithium in THF ( $2 \mathrm{~mL} ; 2.8 \mathrm{mmol}$ ) at $-78^{\circ} \mathrm{C}$. The mixture was stirred under nitrogen at $-10^{\circ} \mathrm{C}$ for 10 min and then cooled to $-78^{\circ} \mathrm{C}$. At the same temperature, a precooled $\left(-20^{\circ} \mathrm{C}\right)$ solution of $32(78 \mathrm{mg}$; 0.11 mmol ) in THF ( 5 mL ) was added. The mixture was stirred at -78 ${ }^{\circ} \mathrm{C}$ for 15 min and then allowed gradually to warm to rt . The excess of reagent was decomposed by aqueous $\mathrm{NH}_{4} \mathrm{Cl}$, the product was taken up into ether, and the ethereal solution was worked up. The solvent was evaporated, and the residue was chromatographed on a column of silica gel with a petroleum ether-ether mixture ( $9: 1$ ) to yield 35 ( $35 \mathrm{mg} ; 75 \%$ ), identical with the product obtained by method A.

38-Chloro-5-cholestene (38a). A mixture of 3a ( 100 mg ) and aluminum chloride ( 20 mg ) in dry DME ( 5 mL ) was heated at $45^{\circ} \mathrm{C}$ for 18 h and monitored by TLC. The mixture was then cooled to $\mathbf{- 2 0}$ ${ }^{\circ} \mathrm{C}$, water ( 1 mL ) was added, and the mixture was allowed to warm to
rt. The mixture was extracted with ether, and the ethereal solution was worked up. Chromatography on silica ( 5 g ) with petroleum ether yielded 38a ( $48 \mathrm{mg} ; 79 \%$ ): mp $94-96{ }^{\circ} \mathrm{C}$ (ethyl acetate; Fluka catalog gives $94-96{ }^{\circ} \mathrm{C}$ ); ${ }^{1} \mathrm{H}$ NMR $\delta 0.68(\mathrm{~s}, 3 \mathrm{H}, 18-\mathrm{H}), 1.04(\mathrm{~s}, 3 \mathrm{H}, 19-\mathrm{H}), 2.49$ (ddd, $\left.J_{\mathrm{gem}}=13.5, J_{4 \alpha \cdot \mathrm{H}, 3 \alpha \cdot \mathrm{H}}=5.1, J_{4 \alpha \cdot \mathrm{H}, 6-\mathrm{H}}=2.1 \mathrm{~Hz}, 1 \mathrm{H}, 4 \alpha-\mathrm{H}\right), 2.56$ ( $\mathrm{m}, 1 \mathrm{H}, 4 \beta-\mathrm{H}$ ), 3.77 (m, $W=32.7 \mathrm{~Hz}, 1 \mathrm{H}, 3 \alpha-\mathrm{H}$ ), 5.38 (brd, $J=5.2$ $\mathrm{Hz}, 6-\mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\delta 11.87(\mathrm{q}), 18.73$ (q), 19.27 (q), $20.97(\mathrm{t}), 22.58$ (q), 22.84 (q), 23.85 (t), 24.28 (t), 28.03 (d), 28.23 (t), 31.79 (d), 31.84 (t), 33.39 (t), 35.79 (d), 36.19 (t), 36.38 ( s$), 39.12$ (t), 39.52 (t), 39.71 (t), 42.31 (s), 43.41 (t), 50.07 (d), 56.14 (d), 56.699 d$), 60.33$ (d), 122.46 (d), 140.77 (s); MS m/z 406 (34, M ${ }^{++}$), 404 (91).
[ $\left.4 \beta^{2} \mathrm{H}\right]$-3 3 -Chloro-5-cholestene (38b): mp $94-96^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR $\delta 0.71$ $(\mathrm{s}, 3 \mathrm{H}, 18-\mathrm{H}), 1.06(\mathrm{~s}, 3 \mathrm{H}, 19-\mathrm{H}), 2.50(\mathrm{~m}, W=6 \mathrm{~Hz}, 1 \mathrm{H}, 4 \alpha-\mathrm{H})$, $3.80(\mathrm{~m}, W=19.7 \mathrm{~Hz}, 1 \mathrm{H}, 3 \alpha-\mathrm{H}), 5.48(\mathrm{dd}, J=5.5$ and $2.0 \mathrm{~Hz}, 1 \mathrm{H}$, $6-\mathrm{H}) ; \mathrm{MS} \geq 95 \%^{2} \mathrm{H}\left(\mathrm{d}_{1}\right)$.

    (20) For typical NMR Hg-shifts of organomercurials, see, for example: Reischl, W.; Kalchhauser, H. Tetrahedron Lett. 1992, 33, 2451.
    (21) Much slower reaction was observed with $\left(\mathrm{CF}_{3} \mathrm{CO}_{2}\right)_{2} \mathrm{Hg} ;(\mathrm{AcO})_{2} \mathrm{Hg}$ did not react at rt at all. For $\mathrm{Hg}^{2+}$, a DME-MeCN mixture was found to be superior to dioxane, which, in turn, was the solvent of choice for Tl (III). ${ }^{11}$

    (25) For recent synthesis of $4 \alpha^{-2} \mathrm{H}$-cholesterol, see: Rabinowitz, M. H. Tetrahedron Lett. 1991, 32, 6081.
    (26) Chemical correlation carried out with deuterated compounds (see below) allowed the two signals to be assigned post festum: the upfield resonance to pro-( $S$ )-H and the downfield signal to pro- $(R)-\mathrm{H}$.
    (27) In the ${ }^{1} \mathrm{H}$ NMR spectrum of unlabeled 4a the $4 \alpha-\mathrm{H}$ appears at 4.17 ppm (dd, $J=8.6$ and 9.1 Hz ) and $4 \beta-\mathrm{H}$ at 3.40 ppm (dd, $J=8.6$ and 4.9 Hz ); the upfield signal exhibits an NOE ( $0.2 \%$ ) with the acetal proton ( $\delta$ 5.17), while the downfield signal shows an NOE ( $15 \%$ ) with $3 \alpha-\mathrm{H}$.

    (43) This reaction employs $\pi$-electrons of the double bond as an internal nucleophile and has been shown to proceed via an $\mathrm{S}_{\mathrm{N}} 2$-like inversion at $\mathrm{C}(19) .40,42$ For nucleophiles other than $\mathrm{H}^{-}$, see: (a) Tadanier, J. J. Org. Chem. 1966, 31, 2124. (b) Kojima, M.; Maeda, M.; Ogawa, H.; Nitta, K.; Ito, T. J. Chem. Soc., Chem. Commun. 1975, 47. (c) Bite, P.; Moravcsik, I. Acta Chim. Acad. Sci. Hung. 1977, 95, 311.
    (44) In the ${ }^{1} \mathrm{H}$ NMR spectrum of 21a the pro-R-H appears at $\delta 0.51$ (d, $J=5.7 \mathrm{~Hz}$ ), while the pro $-S-\mathrm{H}$ at 0.47 (d). In the spectrum of 21 b , two signals appeared as singlets at 0.51 and 0.47 , respectively, in a $32: 68$ ratio. This assignment is based on the stereochemistry of the reduction of aldehyde 17 and assuming $\mathrm{S}_{\mathrm{N}} 2$ inversion at $\mathrm{C}(19)$ in the cyclopropane formation (19b $\rightarrow$ 20b). ${ }^{42,43}$
    (45) In contrast to 1a, carrying the reaction in a DME-MeCN mixture resulted in the formation of a complex mixture of olefinic products, indicating that the $\mathrm{C}(10)$-cation has further migrated along the backbone of the skeleton. For a review on backbone rearrangements, see: Kočovsky, P. Chem. Listy 1979, 73, 583.

    (47) The $\mathrm{LiAlH}_{4}$ reduction of 22a produced cholest-4-en- $3 \beta$-ol as the major product, while 25a afforded 19 -nor-5-methyl- $5 \beta$-cholest- 9 -en- $3 \beta$-ol (ca. $60 \%$ ), identical with an authentic sample, ${ }^{46}$ along with its $\mathrm{C}(3)$-epimer.
    (48) Both ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were indicative of a trisubstituted double bond; treatment with a trace of aqueous HBr led to a conjugated ketone, as revealed by UV absorption of the product.
    (49) The ratio was determined by integration of the signals of $19-2 \mathrm{H}$ in the ${ }^{2} \mathrm{H}$ NMR spectrum for each pair of 19 -epimers. For 22 b the ratio of 2.53 $(W / 2=13.8 \mathrm{~Hz})$ to $2.23(W / 2=12.0)$ was $65: 35$; for 24 b , the signals at 2.42 ( $W / 2=18.0 \mathrm{~Hz}$ ) and $2.12(W / 2=13.8 \mathrm{~Hz})$ were in a $32: 68$ ratio.
    (50) As expected, ${ }^{51}$ attempted radical cyclizations failed: reduction of 3 a with $\mathrm{NaBH}_{4}$ or $\mathrm{Bu}_{3} \mathrm{SnH}$ furnished only the corresponding demercurated alcohol. No cyclobutane ring-closure was observed. ${ }^{52}$ For occasional reports on cyclobutane or cyclopropane formation via a radical addition, see: Jung, M.; Trunovich, I. D.; Lensen, N. Tetrahedron Lett. 1992, 33, 6719 and references therein.

    (54) Lipshutz, B. H.; Kozlowski, J. A.; Breneman, C. M. J. Am. Chem. Soc. 1985, 107, 3197.
    (55) Similarly, $\mathrm{CH}_{2}=\mathrm{MoCl}_{3}$, generated in situ from MeLi and $\mathrm{MoCl}_{5}, 56$ also converted 27 to 29 a in good yield.
    (56) Kauffmann, T.; Fiegenbaum, P.; Wiescholek, R. Angew. Chem., Int. Ed. Engl. 1984, 23, 531.
    (57) It is pertinent to note that the carbonyl group of ketone 30 a proved extremely hindered. Thus, for instance, attempts at Wittig or Peterson olefination were unsuccessful; only $\mathrm{Cp}_{2} \mathrm{Ti}=\mathrm{CH}_{2}$ (Tebbereagent) ${ }^{58}$ was reactive enough to convert this carbonyl into an exo-methylene group.
    (58) (a) Tebbe, F. N.; Parshall, G. W.; Reddy, G. S. J. Am. Chem. Soc 1978, 100, 3611. (b) Pine, S. H.; Zahler, R.; Evans, D. A.; Grubbs, R. H J. Am. Chem. Soc. 1980, 102, 3270.

[^6]:    (59) This reduction can be easily understood as occurring from the convex side of the molecule. The resulting alcohol 31 was also reoxidized to ketone 30a to make sure that no skeletal rearrangement had occurred on reduction.
    (60) The signals of $\mathrm{C}(4)$-protons were much better resolved in ketone 30a than in the parent alcohol 29a. Thus, in the ${ }^{1} \mathrm{H}$ NMR spectrum of $30 \mathrm{a}, 4 \alpha-\mathrm{H}$ appears at $2.90 \mathrm{ppm}(\mathrm{dd}, J=17.6$ and 8.6 Hz ), while $4 \beta-\mathrm{H}$ gives a signal at 2.61 ppm (dd, $J=17.6$ and 6.8 Hz ). In the spectrum of 30 b , the signal of $4 \alpha-\mathrm{H}$ was reduced to ca. $14 \%$ relative to the $4 \beta-\mathrm{H}$ signal. In view of the total deuterium content ( $\geq 94 \%$, as evidenced by MS) in ketone 30b, the corrected integration of the relative intensities of $4 \alpha-\mathrm{H}$ and $4 \beta-\mathrm{H}$ is indicative of a ca. 90:10 ratio of 30b to its 4 -epimer
    (61) No reaction of aldehyde 3a was observed with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{CHR}(\mathrm{R}=\mathrm{H}$, Me , or OMe ) or with $\mathrm{Ph}_{3} \mathrm{As}=\mathrm{CH}_{2}$, presumably due to the lower reactivity of these reagents and/or preferential coordination of P or As to Hg .

[^7]:    (62) We believe that, in this instance, the Lewis acid ( $\mathrm{Me}_{3} \mathrm{Al}$ ) accelerates the conjugate addition, as in its absence only a complex mixture was obtained.
    (63) Attempted radical cyclization of 32, using $\mathrm{NaBH}_{4}$ or $\mathrm{Bu}_{3} \mathrm{SnH}$, gave only the demercurated product. Attempted intramolecular Heck coupling, using various $\mathrm{Pd}(\mathrm{II})$ reagents, resulted solely in $\beta$-elimination. This is in sharp contrast to the analogous cyclizations that occur readily to produce five-membered rings. ${ }^{67}$

    (65) Kirk, D. N.; Hartshorn, M. P. Steroid Reaction Mechanisms; Elsevier: Amsterdam, 1968.
    (66) Diagnostic was the signal of $3 \alpha-\mathrm{H}$ (at 3.77 ppm ). While the width of this multiplet was 32.7 Hz for 38a, in the spectrum of the deuterated compound 38 b (in which $\geq 95 \%$ of deuterium was revealed by HRMS) it was only 19.7 Hz , which indicated that one large (i.e. axial) coupling was missing. This is only compatible with the $4 \beta-2 \mathrm{H}$ configuration. Compared to the spectrum of 38 a , where the $\mathrm{C}(4)$-protons appear at $2.48(4 \alpha-\mathrm{H})$ and 2.55 ( $4 \beta-\mathrm{H}$ ) ppm, the latter signal is absent in the spectrum of 38 b , and the former has lost its geminal coupling ( 13.6 Hz ). For a detailed description of the ${ }^{1} \mathrm{H}$ NMR patterns in $4 \alpha^{-2} \mathrm{H}-$ and $4 \beta-2 \mathrm{H}$-cholesterol, see ref 25 .
