# Aza-Claisen Rearrangements Initiated by Acid-Catalyzed Michael Addition 

Edwin Vedejs" and Marc Gingras<br>Contribution from the Chemistry Department, University of Wisconsin, Madison, Wisconsin 53706

Received August 30, 1993*

#### Abstract

The reaction of allylic amines with dimethyl acetylenedicarboxylate is subject to protic acid catalysis and affords 15, the product of Michael addition and aza-Claisen rearrangement. The sequence involves Michael addition of 4c or 19-21 to generate an intermediate $N$-alkenyl ammonium salt 14 that undergoes a charge-accelerated rearrangement to 15. Toluenesulfonic acid is a useful catalyst for the Michael addition step. Benzoic acid is not effective because the intermediate 14 is competitively dealkylated by the benzoate counterion. In one case, the intermediate $N$-alkenylammonium ion 18 has been detected by ${ }^{1} \mathrm{H}$ NMR spectroscopy and has been observed to undergo the azaClaisen rearrangement at $-20^{\circ} \mathrm{C}$. The sequence of Michael addition and rearrangement can also be catalyzed by Lewis acids. This variation affords 15 at temperatures below $-40^{\circ} \mathrm{C}$. Finally, the Michael addition, aza-Claisen sequence has been applied to cyclic allylic amines 11 and 35 , resulting in ring expansion products 12,36 , and 37.

## Introduction

In 1931, Diels and Alder isolated an unusual 2:1 adduct from the reaction of dimethyl acetylenedicarboxylate (DMAD) and $N$-methylpyrrole 1, but were unable to deduce the structure. ${ }^{19}$ Acheson and Vernon eventually identified the $2: 1$ adduct as 3 and suggested that this substance is formed from an intermediate $1: 1$ adduct 2 via a cyclic mechanism (Scheme 1, eq 1). ${ }^{16}$ This reaction is an early example of the aza-Claisen family of [3,3] sigmatropic shifts. Many related rearrangements involving the addition of allylic amines to acetylenic esters are now known, and recent papers by Kandeel and Vernon ${ }^{2}$ and by Schwan and Warkentin ${ }^{3}$ have explored the thermal reaction in depth. Mariano et al. have used analogous reactions of propiolate esters with allylic amines in alkaloid synthesis, ${ }^{4}$ and several other groups have also made valuable contributions. ${ }^{5}$ To quickly summarize this data (Scheme 2), the $[3,3$ ] rearrangement to 7 can take place by the equivalent of a cyclic transition state (eq 2) or by an ionic pathway involving $\mathrm{C}-\mathrm{N}$ bond heterolysis to the ion pair 6 and recombination to 7 (eq 3). Depending on the conditions, 6 may decompose by enolate C-protonation or by nucleophilic capture of the cation, resulting in net N -dealkylation of 5 and the formation of 8 (eq 4). If the allylic fragment has additional substitution, then the cation can also decompose by elimination reactions. ${ }^{5}$

The DMAD-induced aza-Claisen rearrangement has found limited use for the synthesis of $\alpha$-keto carboxylic acids via

[^0]hydrolysis of 7 followed by decarboxylation, ${ }^{2}$ but other applications remain largely unexplored. We have been interested in potential uses including the preparation of unsaturated acids 10 via controlled enamine hydrolysis ( 7 to 9 ) and base-induced oxaloyl cleavage and also the conversion of cyclic allylic amines such as 11 into medium ring amines $12 .{ }^{6}$ By comparison with other azaClaisen techniques, ${ }^{7}$ the DMAD-amine reactions are appealing for their experimental simplicity. On the other hand, the literature does not make clear why some reactions proceed at room temperature ${ }^{1 \mathrm{a}, 5 \mathrm{sc}, \mathrm{d}}$ while others require heating at $80^{\circ} \mathrm{C}$. ${ }^{3-5}$ The empirical findings suggest either a pronounced dependence of rates on the substrate or the intervention of unknown catalysts.

At least some of the variations in the published reaction temperatures probably reflect medium effects. Thus, Kandeel and Vernon demonstrated that $\mathbf{4 b}$ rearranges at room temperature (time scale of hours), provided that the experiment is done in acetonitrile solution. ${ }^{2}$ The N -dealkylation process (eq 4) also competes, increasingly so as the water content of the acetonitrile is increased ${ }^{2}$ or as the temperature is raised. ${ }^{3}$ Using the best conditions (dry acetonitrile, room temperature), the distilled product 7 b contains ca. $10 \%$ of the byproduct $\mathbf{8 b}$. By comparison, the reaction of 4 a in deuteriochloroform has been reported to occur very slowly at room temperature ( $13 \% 7$ a detected after 6 days). ${ }^{3}$ Fragmentation to 8 (eq 4) is the major pathway ( $37 \%$ ), but additional byproducts are formed as the result of the amineinduced decomposition of chloroform. The authors recognized the possibility that proton transfer from chloroform could influence the mechanism of the aza-Claisen rearrangement. ${ }^{3}$ Thus, protonation of 5 might give the cationic intermediate 14, and subsequent $[3,3]$ shift would benefit from acceleration by the cationic charge at nitrogen. ${ }^{7}$ However, attempts to catalyze the reaction with a weak acid gave puzzling results. Treatment of $4 a$ and DMAD in chloroform with $5 \mathrm{~mol} \%$ benzoic acid added actually decreased the yield of 7a. These observations did not confirm the suspected conversion of 5 to 14 , but the authors left open the possibility that proton transfer may be involved in some unknown way. ${ }^{3}$
The findings from the benzoic acid experiments could be taken as evidence against other variants of an acid-induced process, such as the formation of 14 by the catalyzed Michael addition
(6) Conceptually related ring expansions have recently appeared using a nitrogen adaptation of the Belluš reaction: Edstrom, E. D. J. Am. Chem. Soc. 1991, 113, 6690. See also: Roberts, S. of the tertiary amine to the electron-deficient alkyne. ${ }^{8}$ However, early experiments in our laboratory had shown that the hydrochloride salt of 4 c reacts with methyl propiolate at $20^{\circ} \mathrm{C}$ in chloroform in a relatively fast reaction to give the aza-Claisen product $\mathbf{1 6}$ in $>90 \%$ yield. This observation revives the issue of acid catalysis in the DMAD-induced aza-Claisen reactions. We now report conditions that make this process a viable, high-yielding method for $\mathrm{C}-\mathrm{C}$ bond formation at room temperature or below.

[^1]
## Results

Several different acids were explored as potential catalysts for the reactions of 4 c with DMAD (Table 1). It was found that 10 $\mathrm{mol} \%$ toluenesulfonic acid (TsOH) induces conversion to 7 c in chloroformat room temperature in excellent yield. Trifluoroacetic acid was reasonably effective (entry 3 ), but benzoic acid gave only traces of 7c together with other minor products that were difficult to isolate or identify because of the low conversion. Upon further investigation of reaction conditions, the reasons for this behavior became clear. When the reaction of 4 c with DMAD was repeated using $50 \mathrm{~mol} \%$ benzoic acid (Table 1, entry 5), the usual product 7 c was formed (ca. $47 \%$ as a $3: 1$ mixture of isomers). However, 8 c was the major product ( $50 \%$ ) according to NMR assay, and allyl benzoate (47\%) was also present. This substance is probably formed by the N -dealkylation of 14 a by the nucleophilic benzoate counterion. Because this reaction destroys the intermediate as well as the catalyst, benzoic acid is not an effective catalyst for the conversion of 4 into aza-Claisen products. Acids having relatively non-nucleophilic counterions are necessary for good catalyst turnover.

Since the acid-catalyzed reaction is facile, the possibility exists that previous experiments involving the DMAD or the methyl propiolate induced aza-Claisen rearrangements may have encountered adventitious catalysis. We therefore investigated several other conditions as listed in Table 1 (entries 6-11). Less than $2 \%$ rearrangement could be detected after 24 h in $\mathrm{CDCl}_{3}$ that had been freshly purified by filtration over alumina. Rearrangements reported earlier using deuteriochloroform may

therefore have been influenced by traces of HCl as the catalyst. ${ }^{3}$ In the absence of acid, the reaction is very slow unless higher dielectric solvents are used, such as DMF, acetonitrile, ${ }^{2}$ and propionitrile (entries 6-8). The zwitterionic mechanism via 5 appears to be consistent with the available evidence in these solvents. However, high yields are difficult to obtain because the intermediate 5 is easily diverted into the undesired N -dealkylation pathway if good nucleophiles are present.

To define temperature limits for the cationic aza-Claisen rearrangement, the acid-catalyzed reactions were studied more thoroughly. First, a model compound was prepared by the addition of tri-n-propylamine to DMAD in the presence of TsOH. ${ }^{8}$ This reaction produced a stable salt 17 having a characteristic low-field signal for the vinyl proton at $\delta 7.36 \mathrm{ppm}\left(\mathrm{CDCl}_{3}\right.$ solution). With 17 available as a reference compound, the reaction of the allylic amine 4 c could be probed by NMR methods. Upon mixing 4 c with 0.34 equiv of TsOH at $-40^{\circ} \mathrm{C}$, a complex spectrum resulted containing residual signals of both reactants and traces of the product 15a, together with distinct signals that could be assigned to an ammonium salt 18 . Since 18 could not be isolated, the strongest evidence for this structure is the similarity in chemical shifts for the characteristic vinyl proton in 17 and 18 and the transient nature of the signals assigned to 18. Slow conversion from 18 to 15 a could be monitored over hours at $-20^{\circ} \mathrm{C}$ or minutes above $-10^{\circ} \mathrm{C}$. This experiment shows that the charge-accelerated aza-Claisen rearrangement of $\mathbf{1 8}$ is sufficiently fast to account for the TsOH-catalyzed reactions observed at room temperature. Presumably, the electron-withdrawing ester groups contribute somewhat to lowering the activation barrier. Similar effects are seen in other [3,3] sigmatropic rearrangements. ${ }^{9}$ Thus, 18 rearranges significantly faster than do simple $N$-alkenyl $N$-allylammonium salts. ${ }^{7}$

The acid-catalyzed reactions of Table 1 proceed with minor complications due to the N -dealkylation pathway. Traces of the byproduct 8 were detected in nearly all cases, but the side reaction was problematic only in the case of the benzoic acid catalyzed reaction (entry 5). Qualitatively, the ratio of 15 to 8 increased as the nucleophilicity of the counterion in 14 decreased. Thus, triflic acid gave somewhat cleaner reactions than did TsOH in deuteriochloroform (entry 4 vs entry 2).

These observations indicate that eq 2 and eq 4 have acidmediated counterparts. Acid catalysts activate the alkyne for nucleophilic addition of the amine, and the resulting 14 can undergo the charge-assisted aza-Claisen rearrangement to 15

[^2](Scheme 3). If the counterion is nucleophilic, then competing $\mathrm{S}_{\mathrm{N}}$ 2-dealkylation of 14 can occur to give 8. In the case of the more highly substituted amine 20, the corresponding intermediate 14 may also be capable of N -dealkylation by an $\mathrm{S}_{\mathrm{N}} 1$ process. Formation of $12 \%$ of 8 c in this experiment is consistent with the expected increase in $\mathrm{C}-\mathrm{N}$ heterolysis of 14 in the acid-mediated equivalent of eq 3.
One additional complication was detected with the $\gamma$-disubstituted amine 20. This substrate gave the usual Claisen product 15c in reasonable yield (64\%), but traces (ca. $2 \%$ ) of an isomeric product were also obtained. This material was identified as 22, the product expected from heterolysis of $\mathbf{1 4 c}$, followed by cation recombination with 8 at the less hindered allylic position. The reaction was also unusual in that considerable unreacted starting material $\mathbf{2 0}$ was recovered (24\%). This fact implicates catalyst deactivation due to the N -dealkylation process discussed above and suggests that the allylic cation derived from heterolysis of 14 c can be intercepted by the tosylate counterion of TsOH . Comparable results were observed with the geraniol-derived amine 23 (Scheme 4), but the rearrangement in this case was marginally better ( $73 \%$ isolated yield of 24).
To summarize the above findings, acid catalysis suppresses the undesired fragmentation pathway (eq 4) in simple acyclic substrates. It also lowers the reaction temperature substantially. However, the mechanistic options remain in delicate balance. Structural changes that interfere with effective overlap in the six-center transition state can be expected to promote the alternative pathways. Thus, attempted conversion of $\mathbf{2 5}$ into $\mathbf{2 6}$ gave only the fragmentation product 27 , corresponding to the formation of 8 from the acyclic amines.
Having established conditions for reliable rearrangement of the simple substrates, we turned to the issue of hydrolytic cleavage of representative adducts. As expected, conversion to structures 9 and 10 could be demonstrated easily. Treatment of the rearranged products 15 with aqueous acid (room temperature; two-phase conditions) afforded the oxaloyl derivatives 9 in excellent yield (Table 2). The reactions of entries 1-4 were performed using purified enamine esters, but comparable results were obtained using a one-pot method (entries $5,7,8$ ). In the latter examples, the acid-catalyzed aza-Claisen reaction was done in the usual way, and the crude product was treated directly with dilute acid. The neutral extract consisted of 9 and traces of impurities that could be removed by flash chromatography.
Base-induced oxaloyl cleavage and simultaneous saponification of 9 were accomplished using aqueous sodium hydroxide at room temperature to give $\mathbf{1 0 a}$ or $\mathbf{1 0 b}$ in nearly quantitative yield after

Scheme 3

## Scheme 4

neutralization. The overall conversion from 15b to 10a could be achieved in $>90 \%$ yield if care was taken to purify 9 a . However, the oxaloyl cleavage did not take place cleanly in the more highly substituted 9 c . The product was a $1: 2$ mixture of 10 c and the $\alpha$-keto acid derived from 9c by complete saponification and decarboxylation.

## Lewis Acid Catalysis

In the course of the low-temperature experiments with 4 c we noticed that a small amount of rearrangement had already occurred at $-30^{\circ} \mathrm{C}$. Since the subsequent rearrangement by the observable intermediate 18 was too slow to account for the conversion at $-30^{\circ} \mathrm{C}$, we suspected that the initially formed allenol 13 may be the species responsible for the $-30^{\circ} \mathrm{C}$ rearrangement. Conclusive proof for this conjecture has not been found. However, the above result suggested that the fastest rearrangements should
be observed using catalysts that are less likely to proceed from the reactive allene intermediate to the enoate tautomer corresponding to 14. Lewis acid catalysis was therefore investigated. The Lewis acid coordinated Michael adduct 28 should be capable of direct rearrangement to a Lewis acid complex 29 of the product enamine ester (Scheme 5). The overall conversion would benefit not only from the cationic charge but also from the conversion of an allene subunit into the highly delocalized vinylogous amide 29. In the case of simple hydrocarbon systems, the corresponding transformation from an allene into a conjugated 1,3 diene is favored by $>10 \mathrm{kcal} / \mathrm{mol}$ in terms of overall free energy. ${ }^{10,11} \mathrm{~A}$

fraction of this free energy advantage in the transition state for [3,3] sigmatropic rearrangement should lower the activation barrier for the aza-Claisen process.

In the event, Lewis acids based on the titanium blend reagents ${ }^{12.13}$ were found to catalyze the conversion of allylic amines into the DMAD-derived aza-Claisen products. Thus, treatment of 19 or 21c with DMAD and $10-20 \% \mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}$ gave the expected products of aza-Claisen rearrangement. These reactions were assayed after dilute acid cleavage to give 9a or 9b, and overall conversions of ca. $90 \%$ were demonstrated using the catalyst obtained from BINOL and $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}$ (Table 3).

[^4]A low-temperature experiment was also performed to probe the temperature limits for the process. Thus, a $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ solution of 21a was treated with DMAD and the catalyst generated from $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}+$ AgOTf. ${ }^{12}$ Analysis at $-50^{\circ} \mathrm{C}$ by ${ }^{1} \mathrm{H}$ NMR revealed traces of rearrangement, and further progress of the reaction could be monitored at $-40^{\circ} \mathrm{C}$ over a time scale of hours, ca. $50 \%$ conversion after 2 h . Relatively rapid reaction was observed upon warming the sample to $-20^{\circ} \mathrm{C}$. The Lewis acid catalyzed reactions are the fastest aza-Claisen rearrangements observed to date. Presumably, the rate advantage reflects a combination of the cationic acceleration mentioned earlier, together with the added driving force due to the conversion of an allene into the conjugated enamine. We are aware of one previous example of an aza-Claisen rearrangement that proceeds rapidly at $0^{\circ} \mathrm{C}$, a reaction that involves rearrangement of a vinyl aziridine

to a seven-membered ring. ${ }^{\text {sb }}$ This transformation is accelerated by release of aziridine ring strain. ${ }^{56.14}$ Thus, the Lewis acid catalyzed reactions of DMAD with simple allylic amines can be recommended for applications where the temperature of reaction is critical. However, for routine synthetic applications, the protic acid catalyzed reactions are more practical.

The potential of the Lewis acid catalyzed reactions for asymmetric synthesis was briefly explored. Conversion of an achiral allylic amine into 28 results in the creation of a chiral allene structure and suggests the possibility of control by a chiral Lewis acid catalyst. Alternatively, a chiral allylic amine such as 30 might allow the synthesis of enantiomerically enriched products under conditions of substrate control. In this case, the chiral amine subunit would serve in the less desirable role of a covalently bound auxiliary, and recycling of the amine obtained after hydrolysis of 32 would be necessary. Both of these options have been probed starting with the chiral substrate 30.

The inherent capacity of $\mathbf{3 0}$ for relaying stereochemical information to the newly created stereogenic carbon in 32 was evaluated using the simple achiral catalyst $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}$. A value of $83 \%$ ee was determined after the hydrolytic cleavage to 33 and conversion into the ( $S$ )- $\alpha$-methylbenzylamine-derived amide 34 for NMR assay, and absolute stereochemistry was assigned by X -ray analysis. The rearrangement was then repeated using a variety of Lewis acid catalysts modified with chiral ligands. The catalyst obtained from ( $R$ )- or ( $S$ )-1,1'-bi-2-naphthol and $10 \%$ $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}{ }^{12}$ gave the most promising results with achiral substrates, but ee values in excess of $30 \%$ were not obtained with 21a. In the case of the chiral substrate 30 , the evidence for double asymmetric induction in the derived $\mathbf{3 3}$ proved to be vanishingly small, and ee values of $80 \%$ and $86 \%$ were obtained with the ( $S$ ) and the ( $R$ ) 1, 1'-bi-2-naphthol-derived titanium catalysts, respectively. So far, we have not found conditions where catalyst control is effective by comparison to the best examples of substrate control. ${ }^{15}$ The distance between the metal ligands and the bonding

[^5]sites in the intermediate 31 may be too large to control the initial Michael addition process.

## Ring Expansions

With a variety of catalyzed and uncatalyzed reaction conditions available, the ring expansion applications were explored. Both the five- and the six-membered amine substrates $\mathbf{3 5}$ and 11 were studied using DMAD as the Michael acceptor (Scheme 6). In contrast to the products from acyclic amines, ring-expanded enamines such as 12 were sensitive to hydrolysis during isolation, and they also were easily destroyed by acid catalysts. These problems were most severe in the case of the nine-membered ring system. Thus, the toluenesulfonic acid catalyzed DMAD reaction of 35 was performed at $-15^{\circ} \mathrm{C}$, followed by chromatography over neutral alumina. The product $\mathbf{3 6}$ decomposed on attempted purification on silica gel, but it was obtained sufficiently pure for conclusive characterization by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR ( $57 \%$ recovery). The geometry of the $E$-disubstituted double bond was clear from the characteristic $15.5-\mathrm{Hz}$ coupling in the ${ }^{1} \mathrm{H}$ NMR spectrum. Attempts to perform the reaction under conditions of Lewis acid catalysis were complicated by decomposition during workup, but some product was detected at $-40^{\circ} \mathrm{C}$.
The six-membered amine 11 gave rearrangement products that were better behaved. The simple noncatalyzed reaction of 11 with DMAD in acetonitrile proceeded slowly at room temperature and gave $\mathbf{1 2}$ in $58 \%$ yield. Toluenesulfonic acid catalysis provided an improved $71 \%$ isolated yield of $\mathbf{1 2}$ under the usual conditions in deuteriochloroform. The reaction proceeded slowly between -10 and $0^{\circ} \mathrm{C}$ according to NMR assay. A similar reaction catalyzed by $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2} / \mathrm{AgOTf}^{12}$ was significantly faster and could be monitored $-35^{\circ} \mathrm{C}$. As in the nine-membered ring example, the $E$-disubstituted alkene was the exclusive initial product according to the NMR evidence. The enamine geometry is not rigorously known, but the more stable $E$-configuration as illustrated is supported by ${ }^{13} \mathrm{C}$ NMR chemical shift comparisons with acyclic analogues. ${ }^{2}$
The methyl propiolate reaction was also investigated. This reaction was more troublesome due to increased product sensitivity, and the acid-catalyzed process could not be performed in satisfactory yield. However, the noncatalyzed reaction occurred upon prolonged heating in THF, and the product 37 could be obtained in $71 \%$ yield and reasonable purity (ca. $90 \%$ by NMR assay) after distillation. All of these rearrangements follow the
usual preference for $E$-disubstituted alkene products that has also been reported by Edstrom in the case of the dichloroketeneinduced aza-Claisen ring expansions of similar substrates. ${ }^{6}$

## Summary

The acid-catalyzed conversion from tertiary allylic amines and DMAD into products of aza-Claisen rearrangement has been achieved with both acyclic and cyclic substrates. Examples of the preparative utility of the aza-Claisen process have been demonstrated by the hydrolytic conversion into $\alpha$-keto esters 9 and unsaturated acids $\mathbf{1 0}$ and by the extension to synthesis of medium ring amines 12,36 , and 37 . The reaction takes place at temperatures as low as -40 to $-50^{\circ} \mathrm{C}$ in optimal cases and is mechanistically distinct from the previously reported noncatalyzed reactions. ${ }^{2-5}$ The Lewis acid catalyzed variation is accelerated by the free energy advantage resulting from conversion of an allene derivative into a stabilized conjugated enamine. We have recently encountered other examples of sigmatropic rearrangement where the transition state benefits from a similar allene driving force. ${ }^{16}$

## Experimental Section

General. Analytical thin layer chromatography (TLC) was performed on precoated aluminum-backed silica gel (Merck 60F-254) or neutral alumina (Merck 150F-254). Flash chromatography was done on Merck 60 230-400-mesh silica gel. Melting points are uncorrected (Meltemp apparatus). All reactions were run under a $\mathrm{N}_{2}$ atmosphere except for hydrolysis or oxaloyl cleavage reactions. THF, toluene, and $\mathrm{Et}_{2} \mathrm{O}$ were distilled from sodium/benzophenone. Acetonitrile was distilled over $\mathrm{P}_{2} \mathrm{O}_{5}$ and then redistilled over $\mathrm{K}_{2} \mathrm{CO}_{3}$. Chloroform used in experiments on acid catalysis was passed over basic alumina. Deuterated chloroform was dried over 4- $\AA$ sieves. Methylene chloride was distilled over $\mathrm{P}_{2} \mathrm{O}_{5}$. DMF, PhCN , and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CN}$ were distilled over $\mathrm{CaH}_{2}$. Allylic amines $\mathbf{4 c}, \mathbf{1 1}, \mathbf{1 9}, \mathbf{2 0}, 21,27$, and $\mathbf{3 5}$ were prepared using literature methods. ${ }^{23,17}$

1-(N,N-Di-N-propylamino)-2-carbomethoxy-1,4-pentadiene. Method A: $\mathbf{N}, \mathrm{N}$-Di-n-propylallylammonium Chloride Addition to Methyl Propiolate. A stream of HCl was bubbled into a solution of $N, N$-di- $n$ propylallylamine ( $0.050 \mathrm{~mL}, 39.8 \mathrm{mg}, 0.28 \mathrm{mmol}$ ) in $\mathrm{Et}_{2} \mathrm{O}(2.0 \mathrm{~mL})$. Removal of $\mathrm{Et}_{2} \mathrm{O}$ by slow evaporation under a $\mathrm{N}_{2}$ stream followed by drying under vacuum afforded the crude hydrochloride salt. Di- $n$ propylallylamine ( $0.090 \mathrm{~mL}, 0.517 \mathrm{mmol}$ ) was then injected via a syringe, followed by $\mathrm{CDCl}_{3}(2.0 \mathrm{~mL})$, methyl propiolate ( $22.3 \mathrm{mg}, 0.0236 \mathrm{~mL}$, 0.265 mmol ), and 2-bromomesitylene (Aldrich, $53 \mathrm{mg}, 0.041 \mathrm{~mL}, 0.268$ mmol ) as internal standard. After the reaction mixture was stirred for 16.5 h at $20^{\circ} \mathrm{C}$, the yield of enamine ester 16 was estimated by ${ }^{1} \mathrm{H}$ NMR ( $99 \%$ vs 2-bromomesitylene).

Method B: TsOH-Catalyzed Addition. Dried p-toluenesulfonic acid ( $195 \mathrm{mg}, 1.13 \mathrm{mmol}, 5 \mathrm{~mol} \%$ relative to amine) was dissolved in dichloromethane ( 35 mL ), and freshly distilled $N, N$-di-n-propylallylamine $(4.00 \mathrm{~mL}, 3.180 \mathrm{~g}, 22.5 \mathrm{mmol})$ was added by syringe. Methyl propiolate was then injected while stirring vigorously. A black color developed rapidly. After 24 h at $23^{\circ} \mathrm{C}$, an aliquot was taken and the solvent evaporated. ${ }^{1} \mathrm{H}$ NMR indicated complete consumption of the starting amine. After removal of solvent (aspirator), the residue was purified by distillation under reduced pressure (short-path apparatus) and 16 was collected as a pale yellow liquid, bp $93-94^{\circ} \mathrm{C}(0.08 \mathrm{mmHg})(4.81 \mathrm{~g}$, 95\%): IR (neat ( NaCl ), $\mathrm{cm}^{-1}$ ) 1682, $\mathrm{C}=\mathrm{C}$; 1598, $\mathrm{C}=\mathrm{C}$; 1195, CO , $200-\mathrm{MHz}$ NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 7.49(1 \mathrm{H}, \mathrm{s}), 5.92(1 \mathrm{H}, \mathrm{ddt}, J=16.7$, $10.4,5.2 \mathrm{~Hz}), 4.99(1 \mathrm{H}$, ddt, $J=16.7,2.0,2.0 \mathrm{~Hz}), 4.95(1 \mathrm{H}, \mathrm{ddt}, J$ $=10.4,2.0,2.0 \mathrm{~Hz}), 3.66(3 \mathrm{H}, \mathrm{s}), 3.17-3.05(6 \mathrm{H}, \mathrm{m}), 1.67-1.47(4 \mathrm{H}$, $\mathrm{m}), 0.88(6 \mathrm{H}, \mathrm{t}, J=7.4 \mathrm{~Hz}) ;{ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}, \mathrm{CDCl}_{3}, \mathrm{ppm}$ ) $\delta 170.7,148.2,138.2,113.3,91.5,54.2,50.5,28.8,22.2,10.4$.

Table 1. Acid-Catalyzed Reaction of 4 c with DMAD: Preparation of 15a. The same procedure as described for method $B$, above, was used

Zwitterionic 3-Aza-Claisen Rearrangement to 15a (Solvent Studies): Typical Procedure. To a flask washed with a NaOH solution, rinsed with distilled $\mathrm{H}_{2} \mathrm{O}$, and oven-dried was added $N$, $N$-di- $n$-propylallylamine ( 0.090 $\mathrm{mL}, 0.517 \mathrm{mmol}$ ), followed by $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CN}(1.50 \mathrm{~mL})$ and DMAD ( 0.071 $\mathrm{mL}, 0.577 \mathrm{mmol}$ ). After stirring for 53.5 h at $20^{\circ} \mathrm{C}$, the solvent was removed (aspirator), and flash chromatography on silica gel was done to purify the product using 1:9 acetone/hexane as eluent. The enamine ester 15a was obtained ( $87.2 \mathrm{mg}, 75 \%$ ). The same procedure was applied to similar reactions with different solvents.

Benzoic Acid Induced Reaction of $\mathbf{4 c}$ with DMAD. Benzoic acid ( 51 $\mathrm{mg}, 0.418 \mathrm{mmol}, 50 \mathrm{~mol} \%$ ) was dissolved in $\mathrm{CDCl}_{3}(2.0 \mathrm{~mL})$, and $N, N-$ di-n-propylallylamine ( $119 \mathrm{mg}, 0.150 \mathrm{~mL}, 0.844 \mathrm{mmol}$ ) and DMAD ( $132 \mathrm{mg}, 0.114 \mathrm{~mL}, 0.929 \mathrm{mmol}$ ) were added. After stirring for 29 h , 2-bromomesitylene ( $56.0 \mathrm{mg}, 0.043 \mathrm{~mL}, 0.281 \mathrm{mmol}$ ) as internal ${ }^{1} \mathrm{H}$ NMR standard was added. Formation of the products $15 \mathrm{a}, 8 \mathrm{c}$, and allyl benzoate was confirmed by comparison with authentic spectra. Allyl benzoate was present in $47 \%$ yield on the basis of NMR assay vs the internal standard. After removal of the solvent (aspirator), the residue was purified by flash chromatography on silica gel, 1:9 EtOAc/hexane. The first fractions provided a mixture of allyl benzoate and 2-bromomesitylene, whereas the second fractions gave a $3: 1$ mixture of 15 a and a contaminant assumed to be the $Z$-isomer ( $109 \mathrm{mg}, 0.386 \mathrm{mmol}, 46 \%$ combined). The $Z$-isomer of 15 a could not be separated, and the tentative structure assignment rests on carbomethoxy ${ }^{1} \mathrm{H}$ NMR signals at $\delta 3.71$ and 3.79 ppm and other NMR signals partially overlapping analogous signals of $15 a$ with the correct integral ratio. The third fraction provided

8c (dimethyl 2-[ $N, N$-di- $n$-propylamino]maleate), $112 \mathrm{mg}(54 \%)$ : analytical TLC on silica gel, $1: 9$ acetone/hexane, $R_{f}=0.11$. The product 8 c was obtained as a colorless liquid: molecular ion caled for $\mathrm{C}_{12} \mathrm{H}_{21}-$ $\mathrm{NO}_{4}, 243.147$ 02; found $m / e=243.1467$, error $=1 \mathrm{ppm}$; base peak $=$ $214 \mathrm{amu} ; \mathrm{IR}\left(\right.$ neat $\left.(\mathrm{NaCl}), \mathrm{cm}^{-1}\right) 1745, \mathrm{C}=0 ; 1695, \mathrm{C}=\mathrm{C} ; 1571, \mathrm{C}=\mathrm{C}$; $200-\mathrm{MHz}$ NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 4.58(1 \mathrm{H}, \mathrm{s}), 3.92(3 \mathrm{H}, \mathrm{s}), 3.63(3$ $\mathrm{H}, \mathrm{s}), 3.15-3.00(4 \mathrm{H}, \mathrm{m}), 1.8-1.5(4 \mathrm{H}, \mathrm{m}), 0.88(6 \mathrm{H}, \mathrm{t}, J=7.4 \mathrm{~Hz})$; ${ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT 135, $\mathrm{CDCl}_{3}, \mathrm{ppm}$ ) $\delta 168.2 \mathrm{~s}, 166.0$ $\mathrm{s}, 154.2 \mathrm{~s}, 83.0 \mathrm{~d}, 52.7 \mathrm{q}, 52.6 \mathrm{t}, 50.5 \mathrm{q}, 20.4 \mathrm{t}, 11.1 \mathrm{q}$.

Attempted Conversion of $\mathbf{2 5}$ to 26: Isolation of 27 . Dried $p$-toluenesulfonic acid ( $8.0 \mathrm{mg}, 0.046 \mathrm{mmol}, 14 \mathrm{~mol} \%$ ) was dissolved in $\mathrm{CDCl}_{3}$ ( 1.5 mL ), and freshly distilled 1-methyl-3-methylenepiperidine ( 25 ) (48 $\mathrm{mg}, 0.058 \mathrm{~mL}, 0.325 \mathrm{mmol}$ ) and DMAD ( $55 \mathrm{mg}, 0.048 \mathrm{~mL}, 0.39 \mathrm{mmol}$ ) were added by syringe. The solution was stirred at $20^{\circ} \mathrm{C}$ for 41 h . After removal of solvent (aspirator), the residue was purified by flash chromatography on silica gel, 1:4 acetone/hexane eluent; a nalytical TLC on silica gel, $1: 4$ acetone/hexane, $R_{f}=0.25$. The product 27 obtained was an oil ( $18.5 \mathrm{mg}, 24 \%$ ): molecular ion calcd for $\mathrm{C}_{12} \mathrm{H}_{17} \mathrm{NO}_{4}$, 239.11572 ; found $m / e=239.1163$, error $=2 \mathrm{ppm}$; base peak $=180 \mathrm{amu}$; IR (neat ( NaCl ) $\mathrm{cm}^{-1}$ ) 1744, $\mathrm{C}=\mathrm{O} ; 1695, \mathrm{C}=\mathrm{C} ; 1576, \mathrm{C}=\mathrm{C}$; 200MHz NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 4.98-4.80(2 \mathrm{H}, \mathrm{m}), 4.76(1 \mathrm{H}, \mathrm{s}), 3.93(3$ $\mathrm{H}, \mathrm{s}), 3.67(2 \mathrm{H}, \mathrm{s}), 3.64(3 \mathrm{H}, \mathrm{s}), 3.26-3.21(2 \mathrm{H}, \mathrm{m}), 2.33(2 \mathrm{H}, \mathrm{t}, J$ $=6.4 \mathrm{~Hz}), 1.80-1.66(2 \mathrm{H}, \mathrm{m})$; ${ }^{13} \mathrm{C}$ NMR $(67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT 135, $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 168.0 \mathrm{~s}, 165.9 \mathrm{~s}, 153.9 \mathrm{~s}, 140.6 \mathrm{~s}, 111.4 \mathrm{t}, 85.5 \mathrm{~d}, 53.7$ $\mathrm{t}, 52.7 \mathrm{q}, 50.7 \mathrm{q}, 48.0 \mathrm{t}, 31.8 \mathrm{t}, 25.7 \mathrm{t}$.

Table 2: Acid Hydrolysis of Enamine Esters to $\alpha$-Keto Diesters 9. Dried p-toluenesulfonic acid ( $94 \mathrm{mg}, 0.546 \mathrm{mmol}, 5 \mathrm{~mol} \%$ ) was dissolved in $\mathrm{CHCl}_{3}(30 \mathrm{~mL}$ ). While stirring freshly distilled $N$-cinnamylpyrolidine 21c ( $2.056 \mathrm{~g}, 10.98 \mathrm{mmol}$ ) was added to the solution. After $4.5 \mathrm{~h}, \mathrm{TLC}$ ( $\mathrm{SiO}_{2}, 1: 9 \mathrm{MeOH} / \mathrm{CHCl}_{3}$ ) indicated consumption of the amine and a new intense spot was present ( $\mathrm{I}_{2}$ as developer). Hydrolysis of the crude enamine ester was performed by the addition of $\mathrm{H}_{2} \mathrm{SO}_{4}(5 \%, 50 \mathrm{~mL}$ ) while vigorously stirring the two-phase mixture at $20^{\circ} \mathrm{C}$. The $\mathrm{CHCl}_{3}$ phase was separated and the product further extracted with $2 \times 50 \mathrm{~mL}$ of $\mathrm{CHCl}_{3}$. After combining the organic phases, drying on $\mathrm{Na}_{2} \mathrm{SO}_{4} /$ $\mathrm{MgSO}_{4}$, filtration, and removal of solvent (aspirator), the residue was purified by flash chromatography on silica gel, 1:4 EtOAc/hexane eluent; analytical TLC on silica gel, 3:7 EtOAc/hexane, $R_{f}=0.41$. The keto diester 9 b was obtained as an inseparable (1:1) mixture of diastereoisomers ( $2.76 \mathrm{~g}, 91 \%$ overall): molecular ion calcd for $\mathrm{C}_{15} \mathrm{H}_{16} \mathrm{O}_{5}, 276.0998$; found $m / e 276.0991$, error $=2.5 \mathrm{ppm}$; base peak $=117 \mathrm{amu} ;$ IR (neat $(\mathrm{NaCl})$, $\left.\mathrm{cm}^{-1}\right) 1754, \mathrm{C}=0 ; 1735, \mathrm{C}=0 ; 1256, \mathrm{CO} ; 200-\mathrm{MHz}$ NMR ( $\mathrm{CDCl}_{3}$, ppm) $87.40-7.15(5 \mathrm{H}, \mathrm{m}), 6.14-5.89(1 \mathrm{H}, \mathrm{m}), 5.19-5.04(2 \mathrm{H}, \mathrm{m}), 4.7$ $(1 \mathrm{H}, \mathrm{d}, J=10.3 \mathrm{~Hz}), 4.27-4.11(1 \mathrm{H}, \mathrm{m}), 3.89(1.5 \mathrm{H}, \mathrm{s}), 3.79(1.5 \mathrm{H}$, s), $3.71(1.5 \mathrm{H}, \mathrm{s}), 3.48(1.5 \mathrm{H}, \mathrm{s}) ;{ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT $\left.135, \mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 187.0 \mathrm{~s}, 186.7 \mathrm{~s}, 167.1 \mathrm{~s}, 166.8 \mathrm{~s}, 160.3 \mathrm{~s}, 160.0 \mathrm{~s}$, $139.6 \mathrm{~s}, 139.1 \mathrm{~s}, 137.5 \mathrm{~d}, 137.0 \mathrm{~d}, 128.4 \mathrm{~d}, 128.3 \mathrm{~d}, 127.9 \mathrm{~d}, 127.7 \mathrm{~d}, 126.9$ $\mathrm{d}, 116.9 \mathrm{t}, 116.3 \mathrm{t}, 58.6 \mathrm{~d}, 58.3 \mathrm{~d}, 53.0$ q, 52.8 q, 52.3 q, 52.1 q, 48.9 d .

The following were prepared similarly. 9a: oil, analytical TLC on silica gel, 1:4 EtOAc/hexane, $R_{f}=0.32$. The product was obtained as a 1:1 inseparable mixture of diastereoisomers: molecular ion calcd for $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}_{5}, 214.084$ 04; found $m / e=214.0838$, error $=1 \mathrm{ppm}$; IR (neat $\left.(\mathrm{NaCl}), \mathrm{cm}^{-1}\right) 1754, \mathrm{C}=\mathrm{O} ; 1733, \mathrm{C}=\mathrm{O} ; 1261, \mathrm{CO} ; 270-\mathrm{MHz}$ NMR $\left(\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 5.88-5.70(1 \mathrm{H}, \mathrm{m}), 5.30-4.97(2 \mathrm{H}, \mathrm{m}), 4.11(0.5 \mathrm{H}$, d, $J=7.3 \mathrm{~Hz}), 4.08(0.5 \mathrm{H}, \mathrm{d}, J=7.3 \mathrm{~Hz}), 3.89(1.5 \mathrm{H}, \mathrm{s}), 3.87(1.5$ $\mathrm{H}, \mathrm{s}), 3.73(1.5 \mathrm{H}, \mathrm{s}), 3.70(1.5 \mathrm{H}, \mathrm{s}), 3.12-2.96(1 \mathrm{H}, \mathrm{m}), 1.13(3 \mathrm{H}$, d, $J=6.5 \mathrm{~Hz}$ ); ${ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT $135, \mathrm{CDCl}_{3}, \mathrm{ppm}$ ) $\delta 187.7 \mathrm{~s}, 167.9 \mathrm{~s}, 167.8 \mathrm{~s}, 160.6 \mathrm{~s}, 160.5 \mathrm{~s}, 140.0 \mathrm{~d}, 139.3 \mathrm{~d}, 115.7 \mathrm{t}, 115.4$ $\mathrm{t}, 59.2 \mathrm{q}, 58.6 \mathrm{q}, 53.0 \mathrm{q}, 52.1 \mathrm{q}, 37.1 \mathrm{~d}, 36.7 \mathrm{~d}, 17.6 \mathrm{q} .9 \mathrm{c}$ : analytical TLC on silica gel, 1:4 EtOAc/hexane, $R_{f}=0.46$. The product was obtained as a colorless liquid: molecular ion calcd for $\mathrm{C}_{11} \mathrm{H}_{16} \mathrm{O}_{5}$, 228.099 70; found $m / e=228.1009$; error $=5 \mathrm{ppm}$; IR (neat ( NaCl ), $\left.\mathrm{cm}^{-1}\right) 1756, \mathrm{C}=\mathrm{O} ; 1736, \mathrm{C}=0$; $1263, \mathrm{CO} ; 270-\mathrm{MHz}$ NMR $\left(\mathrm{CDCl}_{3}\right.$, $\mathrm{ppm}) \delta 6.01(1 \mathrm{H}, \mathrm{dd}, J=10.6,17.6 \mathrm{~Hz}), 5.03(1 \mathrm{H}, \mathrm{dd}, J=0.5,17.6$ $\mathrm{Hz}), 5.02(1 \mathrm{H}, \mathrm{dd}, J=10.6,0.5 \mathrm{~Hz}), 4.27(1 \mathrm{H}, \mathrm{s}), 3.86(3 \mathrm{H}, \mathrm{s}), 3.70$ $(3 \mathrm{H}, \mathrm{s}), 1.24(6 \mathrm{H}, \mathrm{d}, J=4.9 \mathrm{~Hz}) ;{ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT $\left.135, \mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 187.8 \mathrm{~s}, 167.5 \mathrm{~s}, 161.1 \mathrm{~s}, 144.3 \mathrm{~d}, 112.8 \mathrm{t}, 61.2 \mathrm{~d}$, $53.2 \mathrm{q}, 52.1 \mathrm{q}, 39.5 \mathrm{~s}, 25.7 \mathrm{q}, 24.0 \mathrm{q}$. 9d: oil, analytical TLC on silica gel, 3:7 EtOAc/hexane, $R_{f}=0.59$; molecular ion calcd for $\mathrm{C}_{16} \mathrm{H}_{24} \mathrm{O}_{5}$, 296.162 29; found $m / e=296.1652$, error $=10 \mathrm{ppm}$; IR (neat, $\mathrm{cm}^{-1}$ ) 1757, $\mathrm{C}=\mathrm{O} ; 1734, \mathrm{C}=\mathrm{O} ; 200-\mathrm{MHz} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 6.01$ ( 0.33 $\mathrm{H}, \mathrm{dd}, J=10.8,17.5 \mathrm{~Hz}$ ), 5.92 ( $0.66 \mathrm{H}, \mathrm{dd}, J=10.8,17.5 \mathrm{~Hz}$ ), $5.16-4.92$ $(3 \mathrm{H}, \mathrm{m}), 4.43(0.67 \mathrm{H}, \mathrm{s}), 4.28(0.33 \mathrm{H}, \mathrm{s}), 3.86(1 \mathrm{H}, \mathrm{s}), 3.85(2 \mathrm{H}$, s), $3.70(2 \mathrm{H}, \mathrm{s}), 3.68(1 \mathrm{H}, \mathrm{s}), 2.01-1.79(2 \mathrm{H}, \mathrm{m}), 1.75-1.40(2 \mathrm{H}, \mathrm{m})$, $1.66(3 \mathrm{H}, \mathrm{s}), 1.57(3 \mathrm{H}, \mathrm{s}), 1.26(2 \mathrm{H}, \mathrm{s}), 1.24(1 \mathrm{H}, \mathrm{s}) ;{ }^{13} \mathrm{C}$ NMR ( 25.8 $\mathrm{MHz}\{\mathrm{H}\}$, DEPT $\left.135, \mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 187.7 \mathrm{~s}, 167.4 \mathrm{~s}, 161.0 \mathrm{~s}, 142.6 \mathrm{~d}$,
$131.6 \mathrm{~s}, 123.8 \mathrm{~d}, 114.5 \mathrm{t}, 60.9 \mathrm{q}, 53.2 \mathrm{q}, 42.7 \mathrm{~s}, 39.3 \mathrm{t}, 25.5 \mathrm{~d}, 22.5 \mathrm{t}, 19.9$ $\mathrm{q}, 18.7 \mathrm{q}, 17.4 \mathrm{q}$.

Oxaloy1 Cleavage, Typical Procedure. Methyl 2-oxo-3-carbomethoxy4 -methyl- 5 -hexenoate ( 9 a) $(67.0 \mathrm{mg}, 0.313 \mathrm{mmol})$ was dissolved in THF ( 2.0 mL ), and an aqueous NaOH solution ( $5 \mathrm{M}, 1.0 \mathrm{~mL}$ ) was added. After the mixture was stirred vigorously at $20^{\circ} \mathrm{C}$ for 19.5 h , a white precipitate appeared. Chloroform ( 15 mL ) was added followed by slow addition of aqueous 1 M HCl to $\mathrm{pH} \approx 1(\mathrm{pH}$ paper). The organic phase was kept, and the aqueous layer was further extracted ( $2 \times 10 \mathrm{~mL}$ of $\mathrm{CHCl}_{3}$ ). Combination of the organic phases, drying on $\mathrm{Na}_{2} \mathrm{SO}_{4} / \mathrm{MgSO}_{4}$, filtration, and evaporation of the solvent (aspirator) afforded 3-methyl4 -pentenoic acid ( $\mathbf{1 0 a}$ ) ( $35.5 \mathrm{mg}, 99 \%$ ). The acid 10 b was similarly prepared. The structures were confirmed by comparison of NMR data with literature data. ${ }^{18}$

One-Pot Aza-Claisen Rearrangement and Oxaloyl Cleavage: Preparation of Methyl 3-Phenyl-4-pentenoate and 3-Phenylpentenolc Acid. To freshly distilled $N$-cinnamylpiperidine ( $3.41 \mathrm{~g}, 3.37 \mathrm{~mL}, 16.9 \mathrm{mmol}$ ) was added dried $p$-toluenesulfonic acid ( $146 \mathrm{mg}, 0.85 \mathrm{mmol}$ ). Diethyl ether ( 90 mL ) and sufficient $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (ca. 16 mL ) to dissolve the ammonium salt were added. The reaction vessel was immersed in a water bath ( 15 ${ }^{\circ} \mathrm{C}$ ), and DMAD ( $2.526 \mathrm{~g}, 2.19 \mathrm{~mL}, 17.77 \mathrm{mmol}$ ) was injected over 2-3 min. A bright yellow color appeared almost instantly. After $23 \mathrm{~h}, \mathrm{TLC}$ analysis indicated incomplete reaction, so a second portion of $p$-toluenesulfonic acid was added ( 146 mg ). After a total of 45 h , the reaction was complete. To hydrolyze the enamine, $\mathrm{H}_{2} \mathrm{SO}_{4}(2 \mathrm{M}, 50 \mathrm{~mL})$ was added, and the mixture was stirred vigorously for 11 h at $23^{\circ} \mathrm{C}$. An aliquot was evaporated and found to contain the keto ester 9 b and traces of DMAD (singlet at $\delta 3.85 \mathrm{ppm}$ ) by NMR analysis. The aqueous layer was discarded, and the ethereal layer was washed with $2 \times 40 \mathrm{~mL}$ of $\mathrm{H}_{2} \mathrm{SO}_{4} 2 \mathrm{M}$. The ether layer was then stirred vigorously with aqueous NaOH solution ( $5 \mathrm{M}, 40 \mathrm{~mL}$ ) at $23^{\circ} \mathrm{C}$ for 24 h . A white precipitate appeared after a few hours, and its volume increased with time. After cooling in an ice-bath, a solution of $\mathrm{H}_{2} \mathrm{SO}_{4}(6 \mathrm{M}, 25 \mathrm{~mL})$ was added dropwise (exothermic). The mixture was then filtered, and the ethereal phase was kept. Further extractions of the aqueous layer ( $5 \times 50 \mathrm{~mL}$ of $\mathrm{CHCl}_{3}$ ), and combination of the organic phases, drying on $\mathrm{Na}_{2} \mathrm{SO}_{4} /$ $\mathrm{MgSO}_{4}$, filtration, and removal of the solvents (aspirator) afforded methyl 3 -phenyl-4-pentenoate ( $2.84 \mathrm{~g}, 88 \%$ overall from N -cinnamylpiperidine) as a colorless liquid with $>95 \%$ purity by NMR comparisons with authentic material. ${ }^{18}$

A portion of the methyl 3-phenyl-4-pentenoate ( $2.332 \mathrm{~g}, 12.26 \mathrm{mmol}$ ) was dissolved in ether ( 25 mL ) and stirred with $5 \mathrm{M} \mathrm{NaOH}(34 \mathrm{~mL})$ for 40 h . The same workup described above for the 3 -methyl a nalogue gave 2.16 g of the acid $10 \mathrm{~b}^{18}$ ( $>95 \%$ yield), $>95 \%$ pure by NMR assay.

Synthesis of 30. tert-Butyl Ether of $\mathbf{N}$-Cbz-Prolinol. In a thick-wall glass tube was weighed the Cbz-prolinol ${ }^{19}(679 \mathrm{mg}, 2.886 \mathrm{mmol})$. After cooling at $-78^{\circ} \mathrm{C}$ (acetone $/ \mathrm{CO}_{2}$ bath), isobutylene was condensed in the tube until the volume of liquid was ca. $2.0 \mathrm{~mL} . \mathrm{CH}_{2} \mathrm{Cl}_{2}(9.0 \mathrm{~mL})$ was then added ( $\mathrm{N}_{2}$ atmosphere), and concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ was injected ( 0.060 mL ). After sealing the tube, the bath was removed and stirring was continued for 8 h at $20^{\circ} \mathrm{C}$. TLC analysis of a sample indicated half conversion, so more isobutylene was condensed into the tube ( 1 mL ), $\mathrm{H}_{2} \mathrm{SO}_{4}$ was added ( 0.100 mL ), and the tube was resealed. After a total of 25.5 h the tube was cooled $\left(-78^{\circ} \mathrm{C}\right)$ and opened, and $\mathrm{K}_{2} \mathrm{CO}_{3}(0.50$ g) was added while stirring vigorously. After removal of solvent (aspirator), the residue was purified by flash chromatography on silica gel, 1:4 acetone/hexane eluent; analytical TLC on silica gel, 3:7 acetone/ hexane, $R_{f}=0.43$. The product was obtained as a colorless oil ( 818 mg , $97 \%$ ): molecular ion calcd for $\mathrm{C}_{1} 7 \mathrm{H}_{25} \mathrm{NO}_{3}, 291.18344$; found $m / e$ 291.1853, error $=6 \mathrm{ppm} ;[\alpha]_{\mathrm{D}}=-58.2^{\circ}(c=10.89 \mathrm{~g} / 100 \mathrm{~mL}, \mathrm{MeOH})$; IR (neat $\left.(\mathrm{NaCl}), \mathrm{cm}^{-1}\right) 1703, \mathrm{C}=\mathrm{O} ; 200-\mathrm{MHz} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta$ 7.50-7.20 ( $5 \mathrm{H}, \mathrm{m}$ ), $5.28-5.01$ ( $2 \mathrm{H}, \mathrm{m}$ ), 4.04-3.80 ( $1 \mathrm{H}, \mathrm{br}$ ), 3.65-3.07 ( $4 \mathrm{H}, \mathrm{m}$ ), 2.09-1.70 ( $4 \mathrm{H}, \mathrm{m}$ ), $1.15(4 \mathrm{H}, \mathrm{s}), 1.09(5 \mathrm{H}, \mathrm{s}) ;{ }^{13} \mathrm{C}$ NMR $\left(125.76 \mathrm{MHz}\{\mathrm{H}\}, \mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 154.55,136.8,136.6,128.1,127.7$, 127.6, 127.5, 72.5, 66.4, 66.2, 62.3, 61.6, 57.7, 57.1, 46.7, 46.5, 28.5, 27.7, 27.3, 27.2, 23.5, 22.6.
tert-Butyl Ether of Prolinol. Pure tert-butyl ether of CBz-protected $(S)-(+)$-prolinol ( $2.24 \mathrm{~g}, 7.69 \mathrm{mmol}$ ) was dissolved in $\mathrm{MeOH}(30 \mathrm{~mL})$, and a small a mount of Pd/C ( 50 mg , Degussa type E101 NO/W, Aldrich Co.) was added. After the system was flushed with $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$, hydrogenation was carried out with a Parr apparatus $\left(20^{\circ} \mathrm{C}, 40 \mathrm{psi} \mathrm{H} 2\right)$ for 24 h . After filtration on a pad of Celite, rinsing, and removal of

[^6]MeOH , distillation of the product gave a clear liquid ( $1.156 \mathrm{~g}, 96 \%$ ): bp $100-105^{\circ} \mathrm{C}, 20 \mathrm{~mm}$, Kugelrohr; $[\alpha]_{\mathrm{D}}=-3.8^{\circ}(c=5.95 \mathrm{~g} / 100 \mathrm{~mL}$, $\mathrm{CHCl}_{3}$ ) IR (neat ( NaCl ), $\mathrm{cm}^{-1}$ ) 3300, NH; 2972, CH; 1197, CO; 200MHz NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta$ 3.45-3.10 ( $3 \mathrm{H}, \mathrm{m}$ ), 3.08-2.78 ( $2 \mathrm{H}, \mathrm{m}$ ), $2.55(1 \mathrm{H}, \mathrm{s}), 1.95-1.65(3 \mathrm{H}, \mathrm{m}), 1.52-1.30(1 \mathrm{H}, \mathrm{m}), 1.18(9 \mathrm{H}, \mathrm{s})$; ${ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT 135, $\mathrm{CDCl}_{3}, \mathrm{ppm}$ ) $\delta 72.0(\mathrm{~s}), 64.4$ (t), 58.1 (d), 45.8 (t), 27.4 (q), 27.2 ( $t$ ), 24.6 (t).
tert-Butyl Ether of N -Cinnamyl Prolinol 30. The tert-butyl ether of ( $S$ )-prolinol ( $51.5 \mathrm{mg}, 0.328 \mathrm{mmol}$ ) was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2.0 \mathrm{~mL})$, and $N, N$-diisopropylethylamine ( $50.9 \mathrm{mg}, 0.069 \mathrm{~mL}, 0.394 \mathrm{mmol}$ ) was added by syringe. Under a $\mathrm{N}_{2}$ atmosphere, cinnamyl bromide ( 64.5 mg , 0.328 mmol ) was added and stirring continued for 24 h at $20^{\circ} \mathrm{C}$. After removal of solvent (aspirator), the residue was purified by flash chromatography on silica gel, $1: 9 \mathrm{MeOH} / \mathrm{CHCl}_{3}$ eluent; a a alytical TLC on silica gel, $1: 9 \mathrm{MeOH} / \mathrm{CHCl}_{3}, R_{f}=0.46$. The product was obtained as a viscous oil ( $67.8 \mathrm{mg}, 76 \%$ ): molecular ion calcd for $\mathrm{C}_{18} \mathrm{H}_{27} \mathrm{NO}$; 273.20929 ; found $m / e=273.2092$, error $=0 \mathrm{ppm} ;[\alpha]_{\mathrm{D}}=-76.6^{\circ}(c=$ $5.20 \mathrm{~g} / 100 \mathrm{~mL}, \mathrm{CHCl}_{3}$ ); IR (neat $\left.(\mathrm{NaCl}), \mathrm{cm}^{-1}\right) 3025,=\mathrm{CH} ; 2971$, $\mathrm{CH} ; 1198, \mathrm{CO} ; 200-\mathrm{MHz}$ NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 7.40-7.15(5 \mathrm{H}, \mathrm{m})$, $6.53(1 \mathrm{H}, \mathrm{d}, J=15.9 \mathrm{~Hz}), 6.34(1 \mathrm{H}, \mathrm{ddd}, J=5.6,7.3,15.8 \mathrm{~Hz}$ ), 3.75 $(1 \mathrm{H}$, ddd, $J=1.2,5.7,14.6 \mathrm{~Hz}), 3.50(1 \mathrm{H}, \mathrm{dd}, J=5.2,8.9 \mathrm{~Hz}), 3.25$ ( $1 \mathrm{H}, \mathrm{dd}, J=6.9,8.8 \mathrm{~Hz}$ ), $3.21-3.06(2 \mathrm{H}, \mathrm{m}), 2.72-2.57(1 \mathrm{H}, \mathrm{m})$, $2.39-2.21(1 \mathrm{H}, \mathrm{m}), 2.05-1.49(4 \mathrm{H}, \mathrm{m}), 1.18(9 \mathrm{H}, \mathrm{s}) ;{ }^{13} \mathrm{C}$ NMR ( 125.76 $\left.\mathrm{MHz}\{\mathrm{H}\}, \mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 137.0,131.6,128.3,127.8,127.0,126.0,72.5$, 65.6, 63.2, 57.7, 54.6, 28.7, 27.4, 22.7.

Lewis Acid Catalysis: General Procedure Using $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}$ for Catalysis of the DMAD Reaction with 19. DMAD ( $81.3 \mathrm{mg}, 0.070 \mathrm{~mL}$, 0.57 mmol ) was added via syringe to a solution of the $N, N$-di- $n$ propylcrotylamine ( $0.100 \mathrm{~mL}, 0.52 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(4.0 \mathrm{~mL}$ ). After cooling at $-40^{\circ} \mathrm{C}$ (Cryocool bath) for a few minutes, a toluene solution $(0.86 \mathrm{M})$ of $\mathrm{TiCl}_{2}(\mathrm{O}: \operatorname{Pr})_{2}{ }^{12.13}(0.120 \mathrm{~mL}, 0.103 \mathrm{mmol})$ was injected and stirring was continued for 14 h . After warming to room temperature, the solution was filtered over a plug of basic alumina with $\mathrm{CHCl}_{3}$. After removal of the solvent (aspirator), the residue was purified by flash chromatography as described earlier to give enamine ester $\mathbf{1 5 b}$ ( 101 mg , 66\%).
( $\pm$ )-(BINOL)TiCl ${ }_{2}$ Procedure. ${ }^{12}( \pm)$-BINOL (Aldrich, $28.6 \mathrm{mg}, 0.10$ mmol ) and $4-\AA$ powdered molecular sieves ( 350 mg ) were dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1.8 \mathrm{~mL})$. After stirring for $5-10 \mathrm{~min}$, a toluene solution of $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}(0.85 \mathrm{M}, 0.116 \mathrm{~mL}, 0.10 \mathrm{mmol})$ was added. A deep red wine color appeared instantly, and stirring was continued for 60 min at $20^{\circ} \mathrm{C} . N$-Cinnamylpyrrolidine 21c ( $98.4 \mathrm{mg}, 0.100 \mathrm{~mL}, 0.525 \mathrm{mmol}$ ) was then added, and the mixture was cooled (Cryocool) to $-40^{\circ} \mathrm{C}$. After $5 \mathrm{~min}, \mathrm{DMAD}(81 \mathrm{mg}, 0.070 \mathrm{~mL}, 0.57 \mathrm{mmol}$ ) was injected. After 18.5 h the reaction was quenched with $\mathrm{HCl} 5 \% / \mathrm{MeOH}(1: 1)(0.20 \mathrm{~mL})$ for 30 min at $-40^{\circ} \mathrm{C}$. After filtration and rinsing with $\mathrm{CHCl}_{3}$, the solvents were partially removed (aspirator) and the residue was hydrolyzed with $\mathrm{HCl}(5 \%)(1.5 \mathrm{~mL})$ while stirring vigorously at $20^{\circ} \mathrm{C}$ for 28 h . The product 9 b was extracted with $3 \times 10 \mathrm{~mL}$ of $\mathrm{CHCl}_{3}$ and was purified as described above, $132 \mathrm{mg}, 92 \%$ overall.

Lewis Acid Catalysis with $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}$ : Conversion of $\mathbf{3 0}$ to $\mathbf{3 3}$ via 32. The catalyst was prepared according to the method of Mikami, Nakai, et al. ${ }^{12}$ In a glovebox was weighed AgOTf ( $27 \mathrm{mg}, 0.105 \mathrm{mmol}, 21 \mathrm{~mol}$ $\%$, Aldrich), $(R)-(+)$-BINOL ( $14.3 \mathrm{mg}, 0.050 \mathrm{mmol}, 10 \mathrm{~mol} \%$, Aldrich $)$, and powdered $4-\AA \AA$ sieves ( 260 mg , Aldrich). $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2.0 \mathrm{~mL})$ was then injected via a syringe, followed by a freshly prepared toluene solution of $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}(0.86 \mathrm{M}, 0.058 \mathrm{~mL}, 0.050 \mathrm{mmol}, 10 \mathrm{~mol} \%)$. The system was kept under $\mathrm{N}_{2}$, and the mixture was stirred vigorously for 7 h at 20 ${ }^{\circ} \mathrm{C}$. After cooling at $-70^{\circ} \mathrm{C}$ in a temperature-regulated bath (Cryocool), the amine 30 was injected ( $137 \mathrm{mg}, 0.127 \mathrm{~mL}, 0.50 \mathrm{mmol}$ ). DMAD ( $77.5 \mathrm{mg}, 0.067 \mathrm{~mL}, 0.55 \mathrm{mmol}$ ) was added after $10-15 \mathrm{~min}$ at $-70^{\circ} \mathrm{C}$. Stirring was continued for 23 h , and the temperature was raised to -65 ${ }^{\circ} \mathrm{C}$ for an additional 47.5 h and finally quenched with a $1: 1$ solution of $0.1 \mathrm{M} \mathrm{NaOH} / \mathrm{MeOH}(0.50 \mathrm{~mL})$. Chromatography on a silica gel plug was used to remove residual starting amine, 3:7 EtOAc/hexane eluent. After removal of solvents (aspirator), the residue was dissolved in $\mathrm{CHCl}_{3}$ ( 5.0 mL ) and hydrolyzed at $20^{\circ} \mathrm{C}$ with $\mathrm{H}_{2} \mathrm{SO}_{4}(1 \mathrm{M}, 3.0 \mathrm{~mL})$ for 30 h . Separation of the $\mathrm{CHCl}_{3}$ layer, further extraction of the aqueous phase ( $2 \times 5 \mathrm{~mL}$ of $\mathrm{CHCl}_{3}$ ), drying of the combined organic phases on $\mathrm{Na}_{2-}$ $\mathrm{SO}_{4} / \mathrm{MgSO}_{4}$, filtration, and removal of solvent (aspirator) provided the crude product, which was purified by flash chromatography on silica gel, 1:5 EtOAc/hexane. Pure 33 was obtained ( $91 \mathrm{mg}, 66 \%$ overall). Basic oxaloyl cleavage under the conditions described before afforded the enantio-enriched acid 10b, which was further coupled with ( $S$ )benzylmethylamine using the mixed anhydride method (see below) to give 34 ( $86 \%$ ee by ${ }^{1} \mathrm{H}$ NMR assay of the amide mixture).

The same procedure as described above was repeated using $(S)$-(-)BINOL in place of $(R)-(+)$-BINOL. The keto diester 33 was obtained ( $101 \mathrm{mg}, 73 \%$ overall). The same assay as before indicated $80 \%$ ee.
In a third experiment, the same procedure was used except that no molecular sieves or BINOL was used. Thus, the reaction was performed with $\mathrm{AgOTf}\left(65 \mathrm{mg}, 0.25 \mathrm{mmol}, 50 \mathrm{~mol} \%\right.$ ), $\mathrm{TiCl}_{2}(\mathrm{OiPr})_{2}$ (crystallized from toluene at $\left.-7{ }^{\circ}{ }^{\circ} \mathrm{C}, 23.6 \mathrm{mg}, 0.10 \mathrm{mmol}, 20 \mathrm{~mol} \%\right), \mathrm{CH}_{2} \mathrm{Cl}_{2}(1.50$ mL ), DMAD ( $85.5 \mathrm{mg}, 0.074 \mathrm{~mL}, 0.60 \mathrm{mmol}$ ), and $30(137 \mathrm{mg}, 0.127$ $\mathrm{mL}, 0.50 \mathrm{mmol}$ ). The reaction time for preforming the Lewis acid was 3 h at $20^{\circ} \mathrm{C}$, and the reaction was performed at $-60^{\circ} \mathrm{C}$ for 4 days. Following $\mathrm{H}_{2} \mathrm{SO}_{4}$ hydrolysis, the keto diester 9 b was obtained ( 85.6 mg , $62 \%$ overall) and oxaloyl cleavage afforded the acid 33 ( $83 \%$ ee, determined as described above).
Preparation of 34. To racemic 3-phenyl-4-pentenoic acid (10b) (84.5 $\mathrm{mg}, 0.477 \mathrm{mmol}$ ) was added $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3.0 \mathrm{~mL})$ and $\mathrm{NEt}_{3}(72 \mathrm{mg}, 0.100$ $\mathrm{mL}, 0.716 \mathrm{mmol})$. After cooling in an ice-bath $\left(3^{\circ} \mathrm{C}\right)$, freshly distilled ethyl chloroformate ( $57 \mathrm{mg}, 0.050 \mathrm{~mL}, 0.525 \mathrm{mmol}$ ) was injected. After stirring for $12 \mathrm{~min},(S)$-(-)-methylbenzylamine (Aldrich, $63.6 \mathrm{mg}, 0.068$ $\mathrm{mL}, 0.525 \mathrm{mmol}$ ) was added, and the bath was removed after 30 min . Stirring was continued at $20^{\circ} \mathrm{C}$ for 18 h . After removal of solvent (aspirator), the diastereoisomers were purified by flash chromatography on silica gel, $1: 3 \mathrm{EtOAc} /$ hexane ( $95.5 \mathrm{mg}, 72 \%$ ). The mixture of products was then separated by an additional flash chromatography on silica gel, 1:4 EtOAc/hexane eluent. The less polar diastereomer $(S, R)-N$ -benzylmethyl-3-phenyl-4-pentenamide was obtained in the first fractions, analytical TLC on silica gel, 3:7 EtOAc/hexane, $R_{f}=0.25$. Pure material was obtained by crystallization from chloroform, $\mathrm{mp} 146-146.5^{\circ} \mathrm{C}$, colorless needles. An X-ray structure determination established the absolutestereochemistry: molecular ion calcd for $\mathrm{C}_{19} \mathrm{H}_{21} \mathrm{NO} ; 279.162$ 32; found $m / e=279.1622$, error $=0 \mathrm{ppm}$; base peak $=105 \mathrm{amu} ;[\alpha]_{\mathrm{D}}=$ $-62.5^{\circ}\left(c=3.53 \mathrm{~g} / 100 \mathrm{~mL}, \mathrm{CHCl}_{3}\right)$; IR (neat $\left.(\mathrm{NaCl}), \mathrm{cm}^{-1}\right) 3437$, NH; 1663, $\mathrm{C}=\mathrm{O} ; 200-\mathrm{MHz}$ NMR $\left(\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 7.40-7.20(10 \mathrm{H}, \mathrm{m})$, $6.10-5.90(1 \mathrm{H}, \mathrm{m}), 5.52-5.33(1 \mathrm{H}, \mathrm{br}$ d, $J=7.1 \mathrm{~Hz}), 5.12-4.92(3 \mathrm{H}$, $\mathrm{m}), 3.94-3.80(1 \mathrm{H}, \mathrm{q}, J=6.9 \mathrm{~Hz}) ;{ }^{13} \mathrm{C}$ NMR $\left(90.56 \mathrm{MHz}\{\mathrm{H}\}, \mathrm{CDCl}_{3}\right.$, $\mathrm{ppm}) \delta 170.1,142.9,142.5,140.3,128.6,128.4,127.6,127.1,126.6$, 126.1, 114.8, 48.4, 46.1, 42.9, 21.2. The second fractions contained the more polar diastereomer: analytical TLCon silica gel, 3:7 EtOAc/hexane, $R_{f}=0.19$; molecular ion calcd for $\mathrm{C}_{19} \mathrm{H}_{2} \mathrm{NO} ; 279.162$ 32; found $m / e=$ 279.1624, error $=0 \mathrm{ppm} ;$ base peak $=105 \mathrm{amu} ;[\alpha]_{\mathrm{D}}=-36.5^{\circ}(c=2.73$ $\left.\mathrm{g} / 100 \mathrm{~mL}, \mathrm{CHCl}_{3}\right) ; 200-\mathrm{MHz}$ NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 7.40-7.20(8 \mathrm{H}$, m), $7.05-6.88(2 \mathrm{H}, \mathrm{m}), 6.10-5.92(1 \mathrm{H}, \mathrm{m}), 5.65-5.50(1 \mathrm{H}, \mathrm{br} \mathrm{d}, J=$ $7.3 \mathrm{~Hz}), 5.13-4.95(3 \mathrm{H}, \mathrm{m}), 3.96-3.80(1 \mathrm{H}, \mathrm{m}), 2.65(1 \mathrm{H}, \mathrm{dd}, J=7.0$, $13.9 \mathrm{~Hz}), 2.50(1 \mathrm{H}, \mathrm{dd}, J=8.3,13.9 \mathrm{~Hz}), 1.39(3 \mathrm{H}, \mathrm{d}, J=6.9 \mathrm{~Hz})$; ${ }^{13} \mathrm{C}$ NMR $\left(90.56 \mathrm{MHz}\{\mathrm{H}\}, \mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 170.1,142.8,142.4,140.5$, $128.6,128.4,127.6,126.9,126.6,125.9,114.7,48.3,46.0,42.8,21.5$. The crystalline diastereomer 33 corresponded to the major product from the reaction of $\mathbf{3 0}$ with DMAD described above. The assay of ee was based on integration of the C -methyl signals at $\delta 1.23 \mathrm{vs} 1.39 \mathrm{ppm}$ for the minor diastereomer.
1-Methyl-3-carbomethoxy-1-azacy clodeca-2,5-diene (37) from 11 and Methyl Propiolate. Todistilled 1-methyl-2-vinylpiperidine ( $185 \mathrm{mg}, 0.200$ $\mathrm{mL}, 1.47 \mathrm{mmol})$ was added THF ( 10.0 mL ) via a syringe, followed by an excess of methyl propiolate ( $520 \mathrm{mg}, 0.550 \mathrm{~mL}, 6.18 \mathrm{mmol}$ ). A condenser was used, and the solution was refluxed under $\mathrm{N}_{2}$ for 72 h . After cooling to room temperature, the solvent was evaporated through a stream of $\mathrm{N}_{2}$, and the volatiles were evaporated overnight with a vacuum pump ( 0.1 mmHg ). Distillation of the product gave 36 as a thick, pale yellow oil: $220 \mathrm{mg}(71 \%)$, bp $150-170^{\circ} \mathrm{C}, 0.005 \mathrm{~mm}$; molecular ion calcd for $\mathrm{C}_{12} \mathrm{H}_{19} \mathrm{NO}_{2} ; 209.14157$; found $m / e=209.1416$, error $=0$ ppm; base peak $=136 \mathrm{amu} ;$ IR (neat $\left.(\mathrm{NaCl}), \mathrm{cm}^{-1}\right) 1680, \mathrm{C}=\mathrm{C} ; 1610$, $\mathrm{C}=\mathrm{C} ; 200-\mathrm{MHz} \mathrm{NMR}\left(\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 7.42(1 \mathrm{H}, \mathrm{s}), 5.42-5.12(2 \mathrm{H}$, $\mathrm{m}), 3.82-3.30(2 \mathrm{H}, \mathrm{m}), 3.67(3 \mathrm{H}, \mathrm{s}), 3.20-2.55(2 \mathrm{H}, \mathrm{m}), 2.97(3 \mathrm{H}$, s), $2.45-0.80(6 \mathrm{H}, \mathrm{m}) ;{ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT $135, \mathrm{CDCl}_{3}$, $\mathrm{ppm}) \delta 171.4 \mathrm{~s}, 148.8 \mathrm{~d}, 131.3 \mathrm{~d}, 123.7 \mathrm{~d}, 93.5 \mathrm{~d}, 51.6 \mathrm{t}, 51.0 \mathrm{q}, 44.5 \mathrm{q}$, $33.4 \mathrm{t} 29.1 \mathrm{t}, 26.2 \mathrm{t}, 21.5 \mathrm{t}$.
1-Methyl-2,3-bis(carbomethoxy)-1-azacy clodeca-2,5-diene (12) from 11 and DMAD with Acid Catalysis. Dried $p$-toluenesulfonic acid (11.0 $\mathrm{mg}, 0.066 \mathrm{mmol}, 10 \mathrm{~mol} \%$ ) was dissolved in dry $\mathrm{CDCl}_{3}(2.0 \mathrm{~mL})$, and $N$-methyl-2-vinylpiperidine ( $83.1 \mathrm{mg}, 0.090 \mathrm{~mL}, 0.663 \mathrm{mmol}$ ) and DMAD ( $122 \mathrm{mg}, 0.106 \mathrm{~mL}, 0.862 \mathrm{mmol}$ ) were added. After 41 h at room temperature, the solvent was removed (aspirator) and the residue was purified by flash chromatography on silica gel, 1:40:59 $\mathrm{NEt}_{3} / \mathrm{EtOAc} /$ hexane eluent, to give $\mathbf{1 2}$ as a pale yellow viscous oil ( $125 \mathrm{mg}, 71 \%$ ): a nalytical TLC on silica gel, 3:7 EtOAc/hexane, $R_{f}=0.41$; molecular ion calcd for $\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{NO}_{4}, 267.141$; found, $266.1400(\mathrm{M}-1)$, error $=0$ ppm ; base peak $=208 \mathrm{amu} ;$ IR (neat $\left.(\mathrm{NaCl}), \mathrm{cm}^{-1}\right) 1733, \mathrm{C}=\mathrm{O} ; 1685$,
$\mathrm{C}=\mathrm{C} ; 1558, \mathrm{C}=\mathrm{C} ; 270-\mathrm{MHz}$ NMR $\left(\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 5.40-5.20(2 \mathrm{H}$, $\mathrm{m})$, $3.81(3 \mathrm{H}, \mathrm{s}), 3.67(3 \mathrm{H}, \mathrm{s}), 3.60-3.20(2 \mathrm{H}, \mathrm{m}), 2.90-2.70(1 \mathrm{H}$, m ), $2.65(3 \mathrm{H}, \mathrm{s}), 2.30-2.20(1 \mathrm{H}, \mathrm{m}), 2.00-1.45(3 \mathrm{H}, \mathrm{m}), 1.40-1.10$ ( $3 \mathrm{H}, \mathrm{m}$ ); ${ }^{13} \mathrm{C}$ NMR ( $67.93 \mathrm{MHz}\{\mathrm{H}\}$, DEPT $135, \mathrm{CDCl}_{3}, \mathrm{ppm}$ ) $\delta 169.4$ s, $167.4 \mathrm{~s}, 153.3 \mathrm{~s}, 132.7 \mathrm{~d}, 121.4 \mathrm{~d}, 108.3 \mathrm{~s}, 56.2 \mathrm{t}, 52.2 \mathrm{q}, 51.3 \mathrm{q}, 40.9$ q, $33.0 \mathrm{t}, 29.4 \mathrm{t}, 28.3 \mathrm{t}, 26.3 \mathrm{t}$.

1-Azacyclononana-2,5-diene Derivative 36 from 35 and DMAD by Acid Catalysis. Dried p-toluenesulfonic acid ( $10 \mathrm{mg}, 0.058 \mathrm{mmol}, 5.5 \%$ ) was dissolved in $\mathrm{CDCl}_{3}(1.50 \mathrm{~mL})$, and 1-methyl-2-vinylpyrrolidine was added ( $117 \mathrm{mg}, 0.140 \mathrm{~mL}, 1.05 \mathrm{mmol}$ ). After cooling to $-78^{\circ} \mathrm{C}$ (acetone $/ \mathrm{CO}_{2}$ bath), DMAD ( $179 \mathrm{mg}, 0.155 \mathrm{~mL}, 1.26 \mathrm{mmol}$ ) was injected, and the solution was stored at $-15^{\circ} \mathrm{C}$ for 48 h (freezer). After warming to room temperature and removal of solvent (aspirator), the residue was purified by chromatography on neutral alumina, 1:9 EtOAc/hexane eluent. The product was obtained as a pale yellow viscous liquid ( $145 \mathrm{mg}, 57 \%$; purity
ca. $90 \%$ by NMR assay of the ester signals): molecular ion calcd for $\mathrm{C}_{13} \mathrm{H}_{19} \mathrm{NO}_{4}, 253.13138$; found $m / e=253.1312$, error $=1 \mathrm{ppm}$; base peak $=194 \mathrm{amu}$; analytical TLC on alumina, 3:7 EtOAc/hexane, $R_{f}=$ 0.70 ; IR (neat ( NaCl ) $\mathrm{cm}^{-1}$ ) 1726, $\mathrm{C}=\mathrm{O} ; 1554, \mathrm{C}=\mathrm{C} ; 1245, \mathrm{CO} ; 200-$ MHz NMR ( $\left.\mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 5.69(1 \mathrm{H}$, ddd, $J=15.5,11.0,4.0 \mathrm{~Hz})$, 5.36 ( $1 \mathrm{H}, \mathrm{ddd}, J=15.5,9.1,4.5 \mathrm{~Hz}$ ), $3.75(3 \mathrm{H}, \mathrm{s}), 3.71(3 \mathrm{H}, \mathrm{s})$, 3.18-3.04 ( $1 \mathrm{H}, \mathrm{m}$ ), 3.03-2.68 ( $2 \mathrm{H}, \mathrm{m}$ ), 2.45-2.21 ( $2 \mathrm{H}, \mathrm{m}$ ), 2.39 ( 3 $\mathrm{H}, \mathrm{s}$ ), 2.20-1.95 ( $1 \mathrm{H}, \mathrm{m}$ ), 1.84-1.47 ( $2 \mathrm{H}, \mathrm{m}$ ); ${ }^{13} \mathrm{C}$ NMR ( 125.76 MHz (H\}, DEPT $\left.135, \mathrm{CDCl}_{3}, \mathrm{ppm}\right) \delta 170.0 \mathrm{~s}, 166.1 \mathrm{~s}, 152.0 \mathrm{~s}, 135.6 \mathrm{~d}, 127.5$ $\mathrm{s}, 125.3 \mathrm{~d}, 56.8 \mathrm{t}, 51.8 \mathrm{q}, 51.5 \mathrm{q}, 38.0 \mathrm{q}, 33.6 \mathrm{t}, 31.7 \mathrm{t}, 27.6 \mathrm{t}$.

[^3]:    (10) Thermodynamic data needed to compare the stability of the allene with 29 are not available. In the simple hydrocarbon analogue, the free energies of formation of 1,2 -butadiene ( $47.8 \mathrm{kcal} / \mathrm{mol}$ ) vs 1,3 -butadiene $(35.75 \mathrm{kcal}$ / mol ) strongly favor the latter. ${ }^{11}$ The aza-analogue should be at least as favorable, and some fraction of this free energy advantage should be felt in the transition state for $[3,3]$ shift.
