Received December 13, 1993

Organic chemical derivatizations of fullerenes such as C₆₀ and C₇₀ by addition reactions are intensely attractive to chemists. Although many derivatives of C₆₀ have now been investigated,^{2,3} only a few discrete, individual products of C₇₀,⁴ such as metal complexes⁵ and alkylated fullerenes,⁶ have been isolated and characterized. While all positions in C₆₀ are identical, five sets of carbon atoms (labeled a–e in Figure 1) and eight distinct types of C–C bonds are available in C₇₀.⁷ It can be anticipated that the different bonds display different reactivities.⁷ In both the reaction of C₇₀ with [Ir(CO)Cl(PPh₃)₂] to give [(η²-C₇₀)Ir(CO)Cl(PPh₃)₂]^{5a} and the hydroalkylations of C₇₀,⁶ attack occurs at the most reactive double bonds (a–b bond) at the poles. Similarly, the osmylation of C₇₀ takes place regioselectively at sites of greater local curvature like the a–b bond.^{5b}

Although photoinduced charge transfer between C₇₀ and electron donors such as aromatic amines,⁸ semiconductor colloid,⁹ and ascorbate¹⁰ can occur, there has so far been no example of formation of a photoadduct. In this communication, we report the novel photochemical reaction¹¹ of C₇₀ with a disilirane¹² affording a cycloadduct as the first silylated C₇₀. This is the first example in which addition occurs at the equatorial belt (e–e bond).

A toluene solution of C₇₀ (3.3 × 10⁻³ M) and 1,1,2,2-tetramesityl-1,2-disilirane¹² (**1**, 3.3 × 10⁻³ M) was photolyzed with a high-pressure mercury-arc lamp (cutoff < 300 nm) to afford a thermally stable 1:1 adduct (**2**) with complete consumption of C₇₀ (Scheme 1). Adduct **2** can be isolated readily in 85% yield by preparative HPLC. No thermal cycloaddition occurs at elevated temperatures up to 100 °C.

Figure 2. (a) UV-vis spectra of C₇₀ (---) and **2** (—) from 190 to 820 nm in hexane. (b) Time-dependent spectral changes of a toluene solution of C₇₀ and **1** upon irradiation.

Scheme 1

FAB mass spectrometry of **2** (C₁₀₇H₄₆Si₂) displays a peak for **2** at 1390–1386 as well as one for C₇₀ at 843–840 which arises from loss of **1**. The UV-vis absorption spectrum of **2** is virtually identical to that of C₇₀ except for subtle differences in the 350–550 nm region (Figure 2a). **2** exhibits a new band at 407 nm but lacks the C₇₀ bands at 381 and 471 nm. Photochemical changes in the absorption spectra are shown in Figure 2b.

The FAB mass and UV-vis spectra of **2** contain a number of unique features, but also suggest that this new fullerene retains the essential electronic and structural character of C₇₀.

The ¹H NMR spectrum of **2** displays six methyl signals at 3.08, 2.20, 2.17, 1.99, 1.95, and 1.75 ppm and four meta-proton signals on the mesityl groups at 6.75, 6.63, 6.58, and 6.52 ppm.¹³ A singlet for the methylene protons at 1.83 ppm is also observed. The ¹³C NMR spectrum¹³ of **2** shows 35 signals for the C₇₀ skeleton: one at 60.61 ppm and the remainder between 128 and 160 ppm.¹⁴ The former signal is attributed to the sp³ fullerene carbons. Twelve signals for four tertiary and eight quaternary carbon atoms, six signals for methyl carbon atoms, and one signal for the methylene carbon atom of the disilirane component are

(13) The NMR measurement was carried out in a binary solvent system (CS₂/CD₂Cl₂ = 3:1).

(14) ¹³C NMR (125 MHz, CS₂/CD₂Cl₂ = 3:1): δ 159.37, 150.13, 149.78, 148.94, 148.56, 148.45, 148.29, 147.68, 147.43, 147.41, 147.16, 146.95, 146.81, 146.17, 146.04, 145.54, 145.26, 145.23, 144.84, 144.47, 143.78, 143.72, 143.35, 142.20, 141.42, 141.08, 140.76, 140.68, 140.54, 139.69, 139.42, 139.38, 138.30, 137.39, 134.46, 134.25, 133.60, 133.09, 132.10, 131.82, 130.34 (*m*-H), 130.17 (*m*-H), 129.97 (*m*-H), 128.87, 128.10 (*m*-H). Overlapping might obscure one signal.

Table 1. Isomers of **2** and Their Symmetries

isomer (bond index of C ₇₀) ^a	5-membered ring	symmetry	equivalency ^b of		
			CH ₂	Si	C(sp ³) on C ₇₀
a—a bond (1.105)	planar	C ₂	x	o	o
	bent	C ₂	x	o	o
	twist	C ₁	x	x	x
a=b bond (1.480)	planar	C ₂	o	x	x
	bent	C ₁	x	x	x
	twist	C ₁	x	x	x

	twist	C ₂	o	o	o

^a Calculated with the AM1 method. ^b o = equivalent; x = nonequivalent.

also observed. In the H—C COSY NMR spectrum, a cross peak corresponding to the methylene protons at 1.83 ppm and the methylene carbon atom of the disilirane component at 9.82 ppm was observed. The ²⁹Si NMR spectrum of **2** shows a peak at -15.88 ppm, which is assigned to the silicon atom of **2**.^{3a,13} Table 1 shows the isomers of 1:1 adducts of C₇₀ and **1** and the equivalency of NMR signals in them. In order to obtain further information on the structure of **2**, a variable temperature ¹H NMR measurement was carried out.¹⁵ Coalescence of the meta-proton signals at 85 °C reflecting conformational change of the molecule was observed, yielding an activation energy of ΔG[‡] = 18.1 kcal/mol.¹⁶ This result reveals the equivalency of aromatic protons above the coalescence temperature, indicative of (a) 1,2-addition across a 6,6-ring junction at the equatorial belt (e—e bond) or (b) 1,4-addition at the same position. These spectral data and Table 1 suggest C₂ symmetry of **2** in which the conformation of the five-membered ring is twisted around an sp³ carbon—carbon bond of the fullerene component.

The equatorial bonding structure for **2**, in which either 1,2-adduct (**2a**) or 1,4-adduct (**2b**) structures are conceivable, was confirmed by AM1 molecular orbital calculation;¹⁷ these C₂ structures correspond to energy minima. The structures of **2** obtained by full geometry optimization at the AM1 level are shown in Figure 3; four bulky mesityl groups are beautifully spaced in C₂ symmetry with the observed equivalency. The high barrier observed is ascribed to the fact that the space between C₇₀ and mesityl groups as well as between mesityl groups becomes filled upon transformation from one twist conformer to the other. An exact assignment of the isomers, however, may await X-ray structural determinations.

The free energy change (ΔG) for electron transfer from **1** to the triplet state of C₇₀ is 11.3 kcal/mol.¹⁸ The rate of disappearance of C₇₀ was suppressed by addition of 10 equiv of

(15) The mixed solvent, CS₂/CD₃C₆D₅ = 1:5, was used.

(16) ΔG[‡] values were calculated according to the Eyring equation.

(17) Dewar, M. J. S.; Jie, C. X. *Organometallics* **1987**, *6*, 1486.

(18) The ΔG value was calculated according to the Rehm—Weller equation²¹ (ΔG = 23.06[E(D/D⁺) - E(A⁻/A) - ΔE_{0,0} - 0.7422]) by using the oxidation potential of **1** (0.81 V vs SCE),¹² the reduction potential of C₇₀ (-0.37 V vs SCE),²² and the triplet energy of C₇₀ (1.43 V).²⁴

Figure 3. Two views of the optimized C₂ structures of **2a** (left) and **2b** (right) calculated with the AM1 method.

diazabicyclo[2.2.2]octane ($E_p = 0.70$ V vs SCE)¹⁹ and 100 equiv of 1,2,4,5-tetramethoxybenzene ($E_p = 0.79$ V vs SCE),¹⁹ each of which has a low oxidation potential and is unreactive to photoreaction by C₇₀. The reaction was inhibited by addition of 10 equiv of rubrene as triplet quencher. The fact that this adduct is also formed upon irradiation at >400 nm where C₇₀ is the only light-absorbing component indicates that C₇₀ triplet, which is known to be efficiently produced from C₇₀ singlet, undergoes interaction with the ground state of **1** forming an exciplex intermediate.^{3a,20}

On the basis of the symmetry derived from the spectral data, **2** is the first isolated product of addition across an equatorial belt (e—e bond) in C₇₀. The reason for the observed regioselectivity on this photocycloaddition of C₇₀ is unknown at the present time. Further studies on the reaction mechanism are in progress.
