Received August 31, 1994

The zaragozic acids and the squalestatins constitute a class of mammalian squalene synthetase inhibitors ($K_i = 29-78$ pM) which have been recently isolated by research groups at Merck¹ and Glaxo.² These natural products share a common [3.2.1]dioxabicyclooctane core, differing exclusively at the C(1) alkyl and C(6) acyl side chains. The structural and stereochemical complexities of these compounds coupled with their potential use as therapeutic agents for the treatment of hypercholesterolemia make the zaragozic acids important targets for synthesis.^{3,4} This communication describes the first synthesis of (+)-zaragozic acid C, 1.

Preparation of the dioxabicyclooctane core commenced with the condensation of D-erythronic γ -lactone 2 with Me₂NH (MeOH, 0 °C), affording the derived trihydroxybutyramide, which was protected to give 3 (Scheme 1).⁵ Addition of 1-ethoxyvinyllithium (ethyl vinyl ether, 'BuLi) to amide 3 yielded an intermediate ketone which underwent chelatecontrolled addition with TMSC=CMgBr to give a 20:1 mixture of alcohol diastereomers 4 as determined by ¹H NMR.⁶ Vinyl ether 4 was converted to diol 6 following ozonolysis, ester reduction (NaBH₄, MeOH), and alkyne desilylation (K₂CO₃, MeOH). Differential protection of the primary and tertiary alcohols with 'BuMe₂SiCl and Me₃SiCl, respectively, furnished 7. Intermediate 7 has been routinely prepared on a 30–40 g scale.

Initial attempts to couple lithium acetylide 8 with aldehyde 9^{4b} gave 40% yield of the desired adduct, with recovered acetylene 7 accounting for the remaining mass balance. Transmetalation of 8 to less basic acetylides with either MgBr₂ or CeCl₃ had little effect on the product distribution. However, addition of 0.5 equiv of anhydrous LiBr to the solution of 8 prior to addition of aldehyde 9 gave the coupled product as a mixture of alcohol epimers in 95% yield.⁷ Dess-Martin oxidation of the mixture of propargyl alcohols provided ynone

(5) D-Erythronic γ lactone is commercially available and can be prepared from D-isoascorbic acid (\$0.04/g), see: Cohen, N.; Banner, B. L.; Lopresti, R. J.; Wong, F.; Rosenberg, M.; Liu, Y.-Y.; Thom, E.; Liebmann, A. A. J. Am. Chem. Soc. **1983**, 105, 3661.

(6) ¹H NMR NOE difference experiments for intermediates possessing the dioxabicyclooctane core provided support for the illustrated stereochemical assignments, see supplementary material.

(7) The effect of LiBr on acetylide addition reactions has been noted: van Rijn, P. E.; Mommers, S.; Visser, R. G.; Verkruijsse, H. D.; Brandsma, L. Synthesis **1981**, 459. 10.⁸ Known methods for the reduction of α , β -unsaturated ynones to their corresponding *trans* enones (e.g., CrSO₄, CrCl₂, Red-Al) led to poor isolated yields of 11 (<10%) with extensive decomposition of the starting material 10.⁹ However, following a protocol developed in our laboratories, semireduction with [Cr(OAc)₂·H₂O]₂ in aqueous THF at 65 °C yielded 11 in 60%.¹⁰

Osmylation of enone 11 proceeded slowly (10% after 48 h at 23 °C) and nonselectively. After considerable experimentation, it was found that dihydroxylation was best accomplished following deprotection of 11 (Bu₄NF). The resulting diol 12 could be osmylated in the presence of either Sharpless ligand, (DHQD)₂PHAL or (DHQ)₂PHAL, with NMO as the reoxidant to give a mixture of diastereomers (64:36 desired:undesired, quantitative yield).¹¹ Treatment of the unpurified osmylation product with HCl in MeOH afforded a mixture of diastereomers (90%, two steps), from which 14 was isolated by chromatography on silica gel following selective protection of both primary hydroxyls as the corresponding silyl ethers. Reaction of the desired diastereomer 14 with trimethylacetyl chloride and subsequent hydrogenolysis of the benzyl ether provided 15.

Completion of the synthesis of zaragozic acid C required installation of the quaternary center at C(4), oxidation at C(8), C(9), and C(10), and attachment of the C(6) acyl side chain (Scheme 2). Swern oxidation of 15 furnished ketone 16, to which TMSC=CLi was added, affording an 86:14 mixture of the desired carbinol along with its diastereomer in 95% yield. The fact that TMSC=CLi adds to 16 to give the desired C(4)epimer as the major product was unexpected. In related studies, we have observed that the ratio of diastereomeric products from 16 is sensitive to the structure of the nucleophile and the reaction conditions.¹² The mixture of diastereomeric products was separated by silica gel chromatography following alkyne desilvlation to give 18. Removal of all three pivaloyl protecting groups on 18 was effected with Dibal-H. The polyol product was subsequently acetylated to provide 19, thus installing the requisite C(4') acetate. Exposure of 19 to mildly acidic conditions led to selective deprotection of the silvl ether at C(8). Semihydrogenation of the terminal acetylene $(H_2, Pd-C, Pd-C)$ C_5H_5N) furnished alkene 20. Oxidation of the primary alcohol at C(8) was accomplished through a two-step sequence which involved Dess-Martin oxidation to the corresponding aldehyde followed by buffered NaClO₂ oxidation and esterification with *N*,*N*'-diisopropyl-*O*-tert-butylisourea to give the tert-butyl ester 21.¹³ Following a similar sequence of steps, the silvl ether at C(10) was removed with HF-pyridine (THF, C_5H_5N) to give 22. Oxidation and esterification afforded the bis(tert-butyl) ester 23. Ozonolysis of 23 and oxidation of the resulting aldehyde with NaClO₂ followed by esterification installed the third carboxylate. Selective hydrolysis of the C(6) and C(7) acetates to furnish 25 was effected with a 0.2% solution of K_2CO_3 in MeOH (0.5 h). Coupling of 25 with side chain 26^1 provided a 1:3 mixture of C(6) and C(7) acylated products, respectively, in 87% combined yield, from which the desired tris(tert-butyl) ester of zaragozic acid C was isolated. Spectral data for both

24 and the tris(*tert*-butyl) ester of zaragozic acid C were identical in all respects to those previously reported.¹ Deprotection of the triester was effected with a 25% solution of trifluoroacetic acid in CH₂Cl₂ (12 h). The synthetic (+)-zaragozic acid C, 1, was identical in all respects (IR, ¹H NMR, ¹³C NMR, HPLC co-injection, MS) to an authentic sample of the natural product.¹⁴
