Received March 27, 1996 ${ }^{\otimes}$

#### Abstract

The synthesis of 2(3),9(10),16(17),23(24)-tetrasubstituted phthalocyanines from 1,2-dicyano-4-alkoxybenzenes or the corresponding isoindolines is reported. In each case, four isomers with $D_{2 h}, C_{4 h}, C_{2 v}$, and $C_{s}$ symmetry are obtained in the statistical expected yield. The separation of the $C_{4 h}$ and the $D_{2 h}$ isomers was achieved successfully for the first time from the other two isomers with newly developed HPLC phases based on $\pi-\pi$ interactions. In one case, phthalocyanine $\mathbf{1 2}$ could be separated into the isomers $\mathbf{1 2 a}-\mathbf{d}$ and characterized by UV/vis and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy. Due to line broadening at room temperature, $T_{1}$ and $T_{2}$ relaxation time measurements of two phthalocyanines ( $\mathbf{3}$ and 12) at different temperatures are carried out. Whether the broad peaks are due to aggregation or due to a short relaxation time is explained.

## Introduction

Phthalocyanine and metallophthalocyanines have been investigated for many years in detail because of their wide application fields, ${ }^{1,2}$ including use in chemical sensors, ${ }^{1,2}$ liquid crystals, ${ }^{1,2}$ Langmuir-Blodgett films, ${ }^{1,2}$ nonlinear optics, ${ }^{1,2}$ optical data storage, ${ }^{1,2}$ and as carrier generation materials in nearIR. ${ }^{1,2}$ Substituted derivatives can also be used for photodynamic cancer therapy and other processes driven by visible light. ${ }^{1,2}$ Pure isomers may show interesting NLO properties, which cannot be investigated in the mixture of all four isomers. A decisive disadvantage of phthalocyanines and metal phthalocyanines is their low solubility in organic solvents or water. The solubility can be increased, however, by introducing alkyl or alkoxy groups into the pheripheral positions of the phthalocyanine framework. ${ }^{3}$ Because of their lower degree of order in the solid state, tetrasubstituted phthalocyanines are more soluble than the corresponding octasubstituted ones. The synthesis of tetrasubstituted metallophthalocyanines and metalfree phthalocyanines substituted in the so-called $1(4), 8(11)$, $15(18), 22(25)$ - and 2(3),9(10), 16(17),23(24)-positions (as shown in Figure 1) normally starts with a 1 - or 2 -substituted phthalodinitrile or the corresponding diiminoisoindolines with an appropriate metal salt in a suitable solvent. ${ }^{1}$ By a statistical condensation reaction in all cases, a mixture of constitutional isomers of the symmetries given in Figure 1 is formed.

For the first time, we were able to separate these constitutional isomers by chromatographic methods (MPLC, HPLC) in the case of $1(4), 8(11), 15(18), 22(25)$-tetrakis[((2-ethylhexyl)oxy)phthalocyaninato]nickel(II) (1). Separation was carried out on a commercially available nitrophenyl column, and the four isomers were completely characterized in terms of their symmetry by UV and ${ }^{1} \mathrm{H}$-NMR spectroscopy. ${ }^{4}$ Separation of these isomers by HPLC methods was possible, because the steric interaction of the peripheral substituents $\mathrm{R}=\mathrm{OCH}_{2} \mathrm{CH}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)$ $\mathrm{C}_{4} \mathrm{H}_{9}$ in the $1(4), 8(11), 15(18), 22(25)$-position with each other and with the phthalocyanine core is comparatively strong. As

a result of this, the planarity of the macrocycle is slightly disturbed. ${ }^{4}$ This can be shown with the $D_{2 h}$ isomer of 1(4), 8(11),15(18),22(25)-tetrakis[((2-ethylhexyl)oxy)phthalocyani-

Scheme 1. Synthesis of $2(3), 9(10), 16(17), 23(24)$ -
Tetrasubstituted Phthalocyanines 3-13

nato]nickel(II). The Q-band in its UV spectrum should be split, but this effect is not observable because the real symmetry is lower than $D_{2 h}$ while the macrocycle is nonplanar. ${ }^{4}$

Our first attempts to separate tetrasubstituted metallophthalocyanines using chromatographic methods were carried out with 2(3),9(10),16(17),23(24)-tetrasubstituted systems, tetrakis(tertbutylphthalocyaninato)nickel(II) (2a-d). However, only enrichment of the $C_{2 v}$ and $C_{s}$ isomers $2 \mathbf{c}, \mathbf{d}$ using MPLC on a silica gel column was possible. ${ }^{5}$

Mixtures of different phthalocyanines obtained by a statistical condensation of two dinitriles have been completely separated by using phthalocyanined silica gels. ${ }^{6}$ The authors report that it is not possible to separate constitutional isomers with these special phases.

In this paper, we now describe the separation of the four constitutional isomers of 2(3),9(10),16(17),23(24)-tetrasubstituted alkoxyphthalocyanines.

## Results and Discussion

The investigated 2(3),9(10),16(17),23(24)-alkoxy-substituted phthalocyanines 3-13 and their synthesis are given in Scheme 1. For the preparation of the 4 -alkoxyphthalodinitriles or the corresponding diiminoisoindolines, the appropriate 4-nitrophthalodinitriles are reacted with the corresponding alcohols, ROH , which are chosen to exhibit different steric hindrance according to R ( R of different size). ${ }^{7}$ From the 4 -alkoxyphthalodinitriles and the corresponding alkoxy-substituted diiminoisoindolines, the nickel 2(3),9(10),16(17),23(24)-alkoxysubstituted phthalocyanines 3-11 and metal-free phthalocyanines $\mathbf{1 2}$ and $\mathbf{1 3}$ are obtained in yields between 11 and $80 \%$.

[^1]All phthalocyanines 3-13, prepared according to Scheme 1, form constitutional isomers as shown by NMR spectroscopy (vide infra), but it is not possible to separate them with commonly available HPLC columns or by recrystallization. Therefore, it is necessary to develop new HPLC phases to separate and characterize these isomers. Another question is whether the expected statistical distribution of $12.5 \% D_{2 h}, 12.5 \%$ $C_{4 h}, 25 \% C_{2 v}$, and $50 \% C_{s}$ isomers occurs in all cases or if the nature of the side chains of the 2(3),9(10),16(17),23(24)substituted phthalocyanines $\mathbf{3 - 1 3}$ changes this distribution.

The characterization of the 2(3),9(10),16(17),23(24)-alkoxysubstituted phthalocyanines $\mathbf{3 - 1 3}$ is carried out by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy. ${ }^{4,5}$ This is possible without difficulty in the case of the recently described $1(4), 8(11), 15(18), 22(25)$-tetrakis[((2ethylhexyl)oxy)phthalocyaninato]nickel(II) (1) compounds. ${ }^{5}$ The 2(3),9(10),16(17),23(24)-substituted phthalocyanines 3-13, however, exhibit very broad signals in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra, as known in general for many substituted phthalocyanines. ${ }^{8}$ Broad signals in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra not only make characterization of the phthalocyanines impossible but also prevent the determination of the symmetry of these molecules.

There are two possible reasons for the broad signals of 2(3), 9(10),16(17),23(24)-alkoxy-substituted phthalocyanines in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra. First, the $T_{1}$ or $T_{2}$ relaxation times of the phthalocyanines 3-13 are very short. This leads to broad signals in the recorded spectra (Heisenberg), because the transition energy is not well defined. Hence, the $T_{1}$ (inversion recovery technique) and $T_{2}$ relaxation time measurements (Carr-Purcell-Meiboom-Gill sequence) are carried out with the 2(3),9(10),16(17),23(24)-alkoxy-substituted phthalocyanines 3 and 12. We may assume that the $T_{2}$ relaxation time is short and thus responsible for the broad signals at 300 K . There are strong dipolar interactions in and between rigid molecules. This leads to a quick defocusing of the magnetization after a NMR pulse, which means a short $T_{2}$ time. ${ }^{9}$ The energy stays constant, and only the entropy increases. For the $T_{1}$ time, we have to discuss a process in which the transition energy of the molecule is released. Relaxation takes place only when the magnitude of the fluctuation fields is nearly the magnitude of the Larmor frequency. This depends on the correlation time $\tau_{c}$. In the correlation time $\tau_{\mathrm{c}}$, all parameters (vibration, rotation, movement, etc.) of a molecule are united. According to theory, the correlation time $\tau_{\mathrm{c}}$ of large and rigid molecules like phthalocyanines is long. The relaxation time $T_{1}$ has a minimum at a defined temperature for each molecule. At higher temperatures, the correlation time $\tau_{c}$ decreases. The spectral density of frequencies near the Larmor frequency becomes smaller, and the relaxation time $T_{1}$ increases. At lower temperatures, the correlation time $\tau_{\mathrm{c}}$ increases, there are fewer magnetic fields in the magnitude of the Larmor frequency, and the relaxation time $T_{1}$ also increases.

The possible second reason for broad signals is aggregation of molecules in solution. This leads to a high-field shift of the signals in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra. The relaxation times $T_{1}$ and $T_{2}$ become shorter, because the correlation time $\tau_{\mathrm{c}}$ increases and dipolar interactions are stronger, as in nonaggregated molecules.

To solve these problems, relaxation time measurements at different temperatures are carried out. For these measurements, a defined amount of 2(3),9(10),16(17),23(24)-tetrakis[((1S)-endo-(-)-bornyloxy)phthalocyaninato]nickel(II) (3) and 2(3), $9(10), 16(17), 23(24)$-tetrakis [((1S)-endo-(-)-bornyloxy)phthalocyanine (12) (mixture of the four isomers) in 0.5 mL of benzene-

$d_{6}$ are used. The phthalocyanines $\mathbf{3}$ and $\mathbf{1 2}$ are chosen because aggregation is less likely with these bulky side groups and the aggregates can be broken at higher temperatures. In Tables $1-5$, the results of the $T_{1}$ and $T_{2}$ measurements of $\mathbf{3}$ and $\mathbf{1 2}$ between 300 and 340 K are shown.

As can be seen from Table 3 for $\mathbf{1 2}$, the $T_{2}$ relaxation time is much shorter than the $T_{1}$ relaxation time. For $\mathbf{3}, T_{2}$ relaxation times cannot be determined. Therefore, it is advantageous to increase the temperature, because then the $T_{2}$ relaxation time increases and the signals show less broadening, so that coupling constants below 2 Hz can be easily resolved. The determination

| $8.8-9.2$ |  |  |  |  |  |

of these short $T_{2}$ times is not exact, because it is technically not possible to choose a shorter delay, as used between the $180^{\circ}$ pulses (in pulse program cpmg, see Experimental Section). In most cases, the measured values cannot be fitted with an exponential function. Therefore, we can only conclude that the broad signals are due to the $T_{2}$ relaxation and the line width decreases with increasing temperature as assumed.

Both phthalocyanines $\mathbf{3}$ and $\mathbf{1 2}$ show a minimum of the $T_{1}$ time between 330 and 335 K without aggregation ( 1 mg of 3 or $\mathbf{1 2}$ in 0.5 mL of benzene, see Tables 1 and 2). At higher and lower temperatures, the relaxation time $T_{1}$ increases as predicted. If aggregation occurs, the $T_{1}$ time becomes shorter, but this depends on the concentration of the solution. At 340 K the $T_{1}$ time of 3 mg of $\mathbf{1 2} \mathrm{in} 0.5 \mathrm{~mL}$ of benzene has the same value as that for the solution of 1 mg of $\mathbf{1 2} \mathrm{in} 0.5 \mathrm{~mL}$ of benzene. But the solution of 3 mg of $\mathbf{1 2}$ in 0.5 mL of benzene shows a decreasing $T_{1}$ time and no minimum (Table 5). This is due to a commencement of aggregation at decreasing temperatures. The solution of 7 mg of $\mathbf{1 2} \mathrm{in} 0.5 \mathrm{~mL}$ of benzene shows only a short $T_{1}$ time with a parabolic course (Table 4), because the concentration of phthalocyanine $\mathbf{1 2}$ is so high that the aggregates rearrange in a very short time, which is not detectable by NMR spectroscopy. Aggregation leads to a 0.2 ppm high-field shift of the aromatic signals of $\mathbf{1 2}$ and to additional broadening of the aromatic signals. In diluted solutions of 12, the aggregates are not stable (Tables 1, 2, and 5). Well-resolved ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra at $330-340 \mathrm{~K}$ can be obtained from the nonaggregated form of $\mathbf{3}$ and 12, as predicted by theory.

As mentioned, phthalocyanines 2-13 cannot be separated with commonly available HPLC phases. Only a nitrophenyl column (Macherey-Nagel ET250/8/4 5NO $\mathrm{NO}_{2}$ ) shows a peak with two shoulders. The problem was solved by designing new HPLC phases based on $\pi-\pi$ interactions between the phthalocyanines and an aromatic part linked to silica gel to separate 2(3),9(10),16(17),23(24)-tetrasubstituted phthalocyanines. A monofunctionalized spacer, (4-aminobutyl)dimethylmethoxysilane (14), was used to synthesize HPLC phases based on silica gel. Activated carboxylic acids (imidazoles) 21-23 can easily be connected at this spacer (14) without dimerization or polymerization of the spacer molecule. Another advantage of monofunctional spacers is an easy purification of the connected products (24-27) by flash chromatography (Scheme 2). The part responsible for the $\pi-\pi$ interactions is the commericially available 2-phenylquinoline-4-carboxylic acid (15) and its derivatives 16, 17, and 19. Scheme 2 shows the synthesis of the HPLC phases 28-31.

Each phase $(\mathbf{2 8}-\mathbf{3 1})$ is identified by elemental analysis, thermogravimetry, and IR, ${ }^{13} \mathrm{C}-\mathrm{CP} / \mathrm{MAS}$ NMR, and ${ }^{29} \mathrm{Si}-\mathrm{CP} /$ MAS spectroscopy. For the (o-nitrophenyl)quinoline phase 29, a contact time variation with ${ }^{29} \mathrm{Si}-\mathrm{CP} / \mathrm{MAS}$ spectroscopy is carried out to determine the covering of this phase in comparison with the data from elemental analysis (EA) and thermogravimetry (TG).

Scheme 2. Synthesis of Phases 28-31

The contact time variation gives information about all Si atoms which are on or near the silica gel surface (cross polarization). The used silica gel is totally porous, so that all Si atoms can be cross-polarized. The ${ }^{29} \mathrm{Si}-\mathrm{CP} / \mathrm{MAS}$ spectrum shows three signals: the signal at 13.4 ppm belongs to the Si atom (M) of the spacer, the one at $-101 \mathrm{ppm}\left(\mathrm{Q}^{3}\right)$ to $\mathrm{SiO}_{3 / 2}(\mathrm{OH})$, and the one at $-110 \mathrm{ppm}\left(\mathrm{Q}^{4}\right)$ to $\mathrm{SiO}_{4 / 2}$. According to this measurement, the (o-nitrophenyl)quinoline phase 29 consists of $57.7 \pm 4.5 \% \mathrm{Q}^{4}, 32.3 \pm 4.3 \% \mathrm{Q}^{3}$, and $10.0 \pm 0.9 \%$ M groups. The covering can be calculated to $0.24 \mathrm{mmol} / \mathrm{g}$ ( 0.69 $\mu \mathrm{mol} / \mathrm{m}^{2}$ ) and is in good agreement with the results of the other methods, EA and TG.

With these phases, HPLC columns are packed and tested with 1,3,5-tri-tert-butylbenzene ( $1 \mu \mathrm{~L}$ of $10 \%$ solution of $1,3,5$-tri-tert-butylbenzene in hexane) to obtain characteristic parameters
for the comparison with other columns. Table 6 shows the characteristics of these columns.

The parameters for columns with good separation qualities are given in the literature ${ }^{10}$ and are compared with the parameters of columns used in this report showing a good agreement (Table 6).

Separation of the phthalocyanines $\mathbf{3 - 1 3}$ is achieved analytically with phases 28-31 and on a preparative scale with phase 29. As eluent, a mixture of either toluene or THF and hexane according to Table 7 is used.

Table 7 shows that the $C_{4 h}$ and $D_{2 h}$ isomers of $\mathbf{3 a}, \mathbf{b}$ (Figure 1) can be separated with phase 29 (Scheme 2) (comparable results were obtained with phase 30). It is also possible to enrich the $C_{2 v}$ isomer of $\mathbf{3}$ to $58 \%$ and the $C_{s}$ isomer to $86 \%$ after three repetitions with the same phase. The symmetries of the separated and enriched isomers of $\mathbf{3}$ are proved by UV/vis, ${ }^{1} \mathrm{H}$ NMR, and ${ }^{13}$ C-DEPT135-NMR spectroscopy. Generally, a separation can be achieved when the side chains or rings of the phthalocyanines contain six or more C atoms (3-13). The separation is better when bulky substituents in the periphery of the phthalocyanine ring (e.g., 3, 12, 6, or 13) are used.

As shown in Table 7, one possibility to achieve better separations of 2(3),9(10),16(17),23(24)-tetraalkoxy-substituted phthalocyanines is to vary the peripheral substituents of the macrocycle. Another possibility is to develop new HPLC phases. First, we improved the electronic situation of the phases by nitration of the phenyl ring of the phenylquinoline system 15 to obtain 16 and 17. With both phases 29 and 30 , it is possible to separate the $D_{2 h}$ and $C_{4 h}$ isomers (Table 7 and Figure 2).

A further alteration of the phenylquinoline system $\mathbf{1 5}$ is carried out by introducing an additional nitro group and a butyl group. The second nitro group leads to a further increase of the $\pi-\pi$ interactions with the phthalocyanines. The more nitro groups added to the basic system 15, the more the retention time of the compounds on the column was increased. An example is given in Table 8.

Therefore, the polarity of the eluent must be raised. The butyl group induces a steric effect. With this phase (31), for the first time it is possible to separate practically all four isomers of $\mathbf{1 2}$, as shown in Figure 3.

The separation of the nickel phthalocyanines 3-11 using phase $\mathbf{3 1}$ is less successful: although a complete separation of the $C_{2 v}$ and $C_{s}$ isomers of $\mathbf{1 2}$ is possible, the separation of the nickel phthalocyanines $\mathbf{3} \mathbf{- 1 1}$ shows only a shoulder between the $C_{2 v}$ and $C_{s}$ isomers.

The aromatic region of the ${ }^{1} \mathrm{H}$-NMR spectra recorded at $330-$ 340 K of the phthalocyanines is used to determine the point group of the separated or enriched isomers. As discussed above, the elevated temperature is necessary to obtain well-resolved spectra. Each phthalocyanine contains four isoindoline units. The typical pattern is a doublet of doublets for $\mathrm{H}_{\mathrm{a}}\left({ }^{3} J_{\text {Hab }}=9.2\right.$ Hz and $\left.{ }^{4} J_{\mathrm{Hab}}{ }^{\prime}=1.9 \mathrm{~Hz}\right)$ (Figure 4), a doublet for $\mathrm{H}_{\mathrm{b}}\left({ }^{3} J_{\mathrm{Hba}}=\right.$ $9.2 \mathrm{~Hz})$, and a doublet for $\mathrm{H}_{\mathrm{b}^{\prime}}\left({ }^{4} J_{\mathrm{Hb}}{ }^{\prime} \mathrm{a}=1.9 \mathrm{~Hz}\right)$. In the cases of the $C_{4 h}$ and $D_{2 h}$ isomers, all isoindoline units are equal, and the pattern of the three aromatic protons is shown only once. The $C_{2 v}$ isomer has two different units, leading to a double signal pattern, and in the $C_{s}$ isomer, all four units are different (Table 9 ), and the pattern of the aromatic protons appears four times for this isomer. In the spectrum of the $C_{s}$ isomer, signal overlap occurs, because of the low chemical shift difference of the different protons of the four units. The $C_{4 h}$ and $D_{2 h}$ isomers show nearly identical NMR spectra (Figure 4), and hence the

$\mathrm{UV} /$ vis spectra are recorded in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to determine the point groups. The spectrum with a split Q-band is assigned to the $D_{2 h}$ symmetry. The split Q-band is due to the symmetry reduction, which necessarily means that the phthalocyanines must be planar and the peripheral substituents do not hinder each other. The splitting of the Q-band is 17 nm . The $C_{4 h}$ isomer shows the smallest width of the Q-band at half-height, as predicted in theory. Table 9 shows the NMR, UV/vis, and IR data of the four isomers of $(\mathrm{BorO})_{4} \mathrm{PcNi}(3)$. In the fingerprint region of the IR spectra of the separated and enriched isomers are differences depending on the symmetry of the isomers. The $D_{2 h}$ and $C_{4 h}$ isomers show fewer bands than the two other ones. Some IR bands of the enriched $C_{s}$ isomer are broad in this region because vibration bands overlap. For the correct assignment of these bands, an analysis of the normal coordinates would be necessary. Figure 4 shows the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{13} \mathrm{C}$-DEPT135-NMR spectra of the pure isomers $\mathbf{3 a}, \mathbf{b}$. The two protons $b$ and $b^{\prime}$ of $\mathbf{3 b}$ show a low-field shift, because two alkoxy groups in the neighborhood decrease the electron density

Figure 3. Separation of $\mathbf{1 2}$ with phase 31. Flow, $1.5 \mathrm{~mL} / \mathrm{min}$; pressure, 78 bar; eluent, $5 \%$ THF and $95 \% n$-hexane; peak detection, 330 nm .

Figure 4. ${ }^{1} \mathrm{H}$-NMR spectra ( $250.13 \mathrm{MHz}, 330 \mathrm{~K}$ ) of the aromatic region of the separated pure isomers $3 \mathbf{a}, \mathbf{b}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$ and ${ }^{13} \mathrm{C}$-DEPT-NMR spectra ( $62.89 \mathrm{MHz}, 300 \mathrm{~K}$ ) of $\mathbf{3 a}, \mathbf{b}$ in $\mathrm{CDCl}_{3}$.
of the aromatic system more than only one group in the case of 3a. For proton a, the influence of the aromatic system is less strong, and the influence of the alkoxy group is the same in both ortho positions; therefore, the shift difference is nearly zero between 3a and 3b (Figure 4).

Table 10 shows the comparable data for the metal-free phthalocyanine 12. With these data, as explained above, the point groups are unequivocally determined. Table 10 and Figure 5 also show that, although the $C_{2 v}(\mathbf{1 2 c})$ and $C_{s}$ isomers (12d) are not separated to the baseline (Figure 3), pure samples of the $C_{2 v}$ and $C_{s}$ isomers can be obtained (Figure 5).

Because all UV/vis spectra of the isomers show a split Q-band, the assignment of the $D_{2 h}$ and $C_{4 h}$ isomers is done by

Figure 5. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra $(250.13 \mathrm{MHz}, 330 \mathrm{~K})$ of the aromatic region of the separated pure isomers $\mathbf{1 2 a}-\mathbf{d}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$.
analogy to the corresponding nickel phthalocyanine 3. Another link for the right assignment is the small Q-band of the $C_{4 h}$ isomer 12a. For all investigated phthalocyanines 3-13, we find the same distribution of the four isomers (by NMR spectroscopy): $12.5 \% C_{4 h}, 25 \% C_{2 v}, 50 \% C_{s}$, and $12.5 \% D_{2 h}$ isomer (Table 7). The peak areas in the HPLC chromatograms of the
phthalocyanines 3-13, detected with UV light at 330 nm , are valid, because all four isomers have the same extinction coefficient at this wavelength. Normally, the $C_{2 v}$ and the $C_{s}$ isomers 3-11 and $\mathbf{1 3}$ are not separated completely from each other, but the peak area of both isomers ( $C_{2 v}$ and $C_{s}$ ) in the chromatograms has, in each case, $75 \%$ accumulation. The aromatic regions in the ${ }^{1} \mathrm{H}$-NMR spectra show always a pattern which is due to $25 \% C_{2 v}$ and $50 \% C_{s}$ isomer.

## Conclusion

In conclusion, we have shown that, by developing new HPLC phases 28-31, which consist of $\pi$-acceptor molecules linked by a spacer (14) to the silicon surface, it is possible for the first time to separate or enrich the four constitutional isomers of 2(3),9(10),16(17),23(24)-tetrasubstituted alkoxyphthalocyanines 3-13 using a comparatively large alkoxy group (e.g., bornyloxy). The determination of the symmetry of the four isomers is carried out by a combination of ${ }^{1} \mathrm{H}-\mathrm{NMR},{ }^{13} \mathrm{C}-\mathrm{DEPT}-\mathrm{NMR}$, IR, and UV/vis spectroscopy, as we have achieved earlier with 1(4),8(11),15(18),22(25)-tetrasubstituted alkoxyphthalocyanines (e.g., 1). The best conditions for ${ }^{1} \mathrm{H}$-NMR measurements of $\mathbf{3}$ and $\mathbf{1 2}$ are determined by investigation of $T_{1}$ and $T_{2}$ relaxation times, depending on temperature and concentration.

## Experimental Section

General. All reactions were performed under dry nitrogen, and all solvents were dried according to standard methods. Commercially available reagents were used as purchased. The 4 -substituted 1,2dicyanobenzenes were synthesized according to reported procedures. ${ }^{7,11}$ NMR spectra were recorded on Bruker AMX 400, ASX 300, or ARX 250, IR spectra on a Bruker IFS 48, mass spectra on a Varian MAT 711, and UV/vis spectra on Shimadzu UV-365 and UV-3102 PC spectrometers. Elemental analysis were carried out using a Carlo Erba elemental analyzer 1106 and thermogravimetry on a Netsch STA 409 apparatus. HPLC were conducted using Beckmann System Gold (Autosampler 507, programmable solvent module 126 and diode array detector module 168) and Kronlab systems (Mastercron 4 highperformance pump, Dynamax absorbance detector module UV-1, and Gilson fraction collector Model 201). Melting points were taken on a Gallenkamp melting point apparatus and were uncorrected.

The $T_{1}$ and $T_{2}$ measurements were carried out on a Bruker ARX 250. Acquisition and processing of the data were done with the software of Bruker UXNMR 941002.2 and XWINNMR 1.1. For each $T_{1}$ measurement, the inversion recovery technique is used (pulse program, Bruker t1ir ARX version). The relaxation delay is 5 s , and the delay between the $180^{\circ}$ and $90^{\circ}$ pulses is incremented with 40 ms and 64 increments. For each $T_{2}$ measurement, the Carr-Purcell-Meiboom-Gill sequence is used (pulse program, Bruker cpmg ARX version). The relaxation delay is 5 s , and the delay between the $180^{\circ}$ pulses (fixed echo time) is 2 ms . The length of the $180^{\circ}$ pulse train is incremented with 10 ms and 64 increments. All relaxation time measurements were carried out in benzene- $d_{6}$ without degassing the solution. A degassed (nitrogen) sample of $\mathbf{3}$ shows the same relaxation times as a nondegassed solution.

The separation of the isomers of $\mathbf{3}$ and $\mathbf{1 2}$ was carried out by preparative HPLC. Portions of 10 mg of phthalocyanine in 10 mL of eluent were given on the preparative column $(250 \mathrm{~mm} \times 16 \mathrm{~mm}$ with a precolumn, $30 \mathrm{~mm} \times 16 \mathrm{~mm}$ ). The separation was repeated eight times to get enough pure isomers for ${ }^{13} \mathrm{C}$-NMR spectroscopy. The samples of pure or enriched isomers were collected with a fraction collector (see above). The samples were evaporated to dryness and washed with methanol to remove impurities of the used solvents.

For ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy, 1 mg of each sample was dissolved in $\mathrm{CDCl}_{3}$ and measured at high temperature ( $330-340 \mathrm{~K}$ ). For ${ }^{13} \mathrm{C}$-DEPTNMR spectroscopy, 4 mg of each sample was dissolved in $\mathrm{CDCl}_{3} / \mathrm{CS}_{2}$ (3:1) and measured at 300 K .

General Procedure for the Synthesis of Phthalocyanines 3-11. 1,2-Dicyano-4-alkoxybenzene ( 2 mmol ) and nickel chloride ( 64.95 mg , 0.5 mmol ) were dissolved in 5 mL of absolute solvent (DMF or DMAE). This mixture was heated under reflux for several hours (Table 11). After the reaction, the solvent was distilled and the residue purified by chromatography over silica gel as shown in Table 11. Then purified product was then dissolved in a small amount of dichloromethane (DCM) and precipitated with methanol.

(Mononitrophenyl)quinolinecarboxylic acids (16, 17). 2-Phen-ylquinoline-4-carboxylic acid ( $\mathbf{1 5}, 4 \mathrm{~g}, 16 \mathrm{mmol}$ ) was slowly added to a cold solution of 5 mL of $65 \% \mathrm{HNO}_{3}$ and 7 mL of $100 \% \mathrm{H}_{2} \mathrm{SO}_{4}$. The cooling bath was removed, and the mixture stirred for 2 h at room temperature. The mixture was heated to $50^{\circ} \mathrm{C}$ and stirred again for 2 h. The solution was cooled and poured into ice water. The obtained residue was washed with water until pH 7 , dried at $60^{\circ} \mathrm{C}$, and recrystallized from ethanol. The first fraction contained pure ( $o$ -nitrophenyl)quinoline-4-carboxylic acid (16), and all other fractions contained both possible products 16 and 17. Fractionated recrystalli-
zation from acetone gave ( $p$-nitrophenyl)quinoline-4-carboxylic acid (17): yield $3 \mathrm{~g}(63.8 \%)$ as yellow powder, decomposes at $200^{\circ} \mathrm{C}\left(\mathrm{CO}_{2}\right.$ evolution).

For 16: yield 1.2 g ; MS $\mathrm{m} / \mathrm{z}$ (relative intensity) $294.1\left(\mathrm{M}^{+}\right), 249.0$, 204.0 (100), 176.0, 124.5, 101.0, 87.9, 74.9; ${ }^{1} \mathrm{H}-\mathrm{NMR}$ (DMSO, 250 $\mathrm{MHz}) \delta 7.75(\mathrm{t}, 1 \mathrm{H}), 7.88(\mathrm{t}, 1 \mathrm{H}), 8.19(\mathrm{~d}, 1 \mathrm{H}), 8.36(\mathrm{~d}, 2 \mathrm{H}), 8.53(\mathrm{~d}$, 2 H ), $8.56(\mathrm{~s}, 1 \mathrm{H}), 8.64(\mathrm{~d}, 1 \mathrm{H}), 14.01(\mathrm{~s}, \mathrm{br}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}-\mathrm{NMR}$ (DMSO, 62.89 MHz ) $\delta 119.46,123.83,124.01,125.43,128.43,128.62,129.98$, 130.56, 138.02, 143.67, 148.16, 148.31, 153.53, 167.35; IR (KBr disk) $v 3093 \mathrm{~s}, 2921 \mathrm{~s}, 2530 \mathrm{~s}, 1717$ (s), 1595 (m), 1531 (s), 1348 (s), 1244 $(\mathrm{m}), 1200(\mathrm{~m}), 798(\mathrm{~m}), 762(\mathrm{~m}), 696(\mathrm{~m}) \mathrm{cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{16} \mathrm{H}_{10} \mathrm{~N}_{2} \mathrm{O}_{4}: \mathrm{C}, 65.31 ; \mathrm{H}, 3.43 ; \mathrm{N}, 9.52$. Found: C, 65.33; H, 3.63; N, 9.60.

For 17: yield $0.55 \mathrm{~g} ; \mathrm{MS} \mathrm{m} / \mathrm{z}$ (relative intensity) $294.1\left(\mathrm{M}^{+}\right), 249.0$, 204.0 (100), 176.0, 124.5, 101.0, 87.9, 74.9; ${ }^{1} \mathrm{H}$-NMR (DMSO, 250 MHz) $\delta 7.76(\mathrm{t}, J=7.0 \mathrm{~Hz}, 1 \mathrm{H}), 7.85(\mathrm{t}, J=8.0 \mathrm{~Hz}, 1 \mathrm{H}), 7.92$, (dd, $J=7.0,2.2 \mathrm{~Hz}, 1 \mathrm{H}), 8.19(\mathrm{~d}, J=8 \mathrm{~Hz}, 1 \mathrm{H}), 8.34(\mathrm{dd}, J=7.5,2.2$ $\mathrm{Hz}, 1 \mathrm{H}), 8.56(\mathrm{~s}, 1 \mathrm{H}), 8.65(\mathrm{~d}, J=8.4 \mathrm{~Hz}, 1 \mathrm{H}), 8.72(\mathrm{~d}, J=7.6 \mathrm{~Hz}$, $1 \mathrm{H}), 9.05(\mathrm{t}, J=1.8 \mathrm{~Hz}, 1 \mathrm{H}), 14.10(\mathrm{~s}, \mathrm{br}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}-\mathrm{NMR}$ (DMSO, $62.89 \mathrm{MHz}) \delta 119.04,121.51,123.79,124.30,125.39,128.34,129.85$, 130.49 (2C), 133.36, 138.03, 139.36, 148.22, 148.44, 153.35, 167.38; IR (KBr disk) $v 3001$ (w), 2932 (w), 2850 (w), 2642 (w), 1699 (s), 1514 (s), 1416 (m), 1348 (s), 1319 (m), 1277 (m), 1259 (m), 860 (m), $847(\mathrm{~m}), 762(\mathrm{~m}) \mathrm{cm}^{-1}$. 2-(p-Butylphenyl)quinoline-4-carboxylic Acid (18). Isatin (5.6 g, $0.038 \mathrm{~mol})$ and $p$-butylacetophenone $(6.7 \mathrm{~g}, 0.038 \mathrm{~mol})$ were added to a saturated solution of $\mathrm{KOH}(6.4 \mathrm{~g}, 0.114 \mathrm{~mol})$. Enough ethanol ( $20-$ 40 mL ) was added to render the mixture homogeneous, and the mixture was heated to $70-80^{\circ} \mathrm{C}$ for 48 h . The reaction mixture was evaporated and the residue dissolved in $\mathrm{H}_{2} \mathrm{O}$. The aqueous solution was acidified
with $50 \%$ acetic acid. The creamy precipitate was purified by recrystallization from ethanol: yield 4.9 (43\%) as light red powder; $\mathrm{mp} 212{ }^{\circ} \mathrm{C}$; MS m/z (relative intensity) $306\left(\mathrm{M}^{+}\right), 276,262$ (100), 215; ${ }^{1} \mathrm{H}-\mathrm{NMR}$ (acetone, 250 MHz$) \delta 0.96(\mathrm{t}, 3 \mathrm{H}), 1.39(\mathrm{sx}, 2 \mathrm{H}), 1.68(\mathrm{q}$, $2 \mathrm{H}), 2.73(\mathrm{t}, 2 \mathrm{H}), 7.43(\mathrm{~d}, 2 \mathrm{H}), 7.68(\mathrm{t}, 1 \mathrm{H}), 7.84(\mathrm{t}, 1 \mathrm{H}), 8.2(\mathrm{~d}, 1 \mathrm{H})$, $8.28(\mathrm{~d}, 2 \mathrm{H}), 8.57(\mathrm{~s}, 1 \mathrm{H}), 8.84(\mathrm{~d}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}-\mathrm{NMR}$ (acetone, 250 MHz ) $\delta 13.7,22.5,33.8,35.5,120.0,124.4,126.0,127.6,127.8,129.3,130.2$, $130.4,136.5,136.9,145.3,149.6,156.7,165.1$; IR (KBr disk) $v 2956$ (m), 2928 (s), 2858 (m), 1722 (m), 1645 (w), 1616 (m), 1591 (s), 1418 (m), 1393 (m), 1245 (w) cm ${ }^{-1}$. Anal. Calcd for $\mathrm{C}_{20} \mathrm{H}_{19} \mathrm{NO}_{2}$ : C, 78.65; H, 6.28; N, 4.59. Found: C, 78.69; H, 6.13; N, 4.48.

2-(p-Butyldinitrophenyl)quinoline-4-carboxylic Acid (19). 18 (4.5 $\mathrm{g}, 14.7 \mathrm{mmol}$ ) was slowly added to a cold solution of 5 mL of $100 \%$ $\mathrm{HNO}_{3}$ and 7 mL of $100 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ and worked up analogously to (mononitrophenyl)quinolinecarboxylic acid 16 or 17. The yellow powder was recrystallized from toluene: yield $2.5 \mathrm{~g}(42.8 \%)$ of yellow powder; mp $182{ }^{\circ} \mathrm{C}$; several constitutional isomers; MS $\mathrm{m} / \mathrm{z}$ (relative intensity) $396\left(\mathrm{M}^{+}\right), 378(100 \%), 361,336,308,204 ;{ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}\right.$, $250 \mathrm{MHz}) \delta 0.91(\mathrm{t}, 3 \mathrm{H}), 1.36(\mathrm{sx}, 2 \mathrm{H}), 1.59(\mathrm{q}, 2 \mathrm{H}), 2.85(\mathrm{t}, 2 \mathrm{H})$, $7.51(\mathrm{~d}, 1 \mathrm{H}), 7.7(\mathrm{t}, 1 / 2 \mathrm{H}), 7.84(\mathrm{t}, 1 / 2 \mathrm{H}), 8.04(\mathrm{~d}, 1 / 2 \mathrm{H}), 8.22(\mathrm{~d}, 1 / 2 \mathrm{H})$, $8.35-8.53(\mathrm{~m}, 2 \mathrm{H}), 8.6(\mathrm{~d}, 1 / 2 \mathrm{H}), 8.65(\mathrm{~s}, 1 / 2 \mathrm{H}), 8.75(\mathrm{~d}, 1 / 2 \mathrm{H}), 9.07(\mathrm{~d}$, $\left.{ }^{1 / 2} \mathrm{H}\right) ;{ }^{13} \mathrm{C}-\mathrm{NMR}(\mathrm{DMSO}, 250 \mathrm{MHz}) \delta 13.6,22.0,31.4,32.2,115.2$, 120.7, 122.9, 124.7, 124.8, 125.2, 128.3, 129.4, 131.5, 132.7, 135.9, 138.4, 138.9, 146.7, 148.2, 149.8, 155.1, 166.8; IR (KBr disk) v 3101 (w), 2957 (m), 2930 (m), 1713 (m), 1624 (w), 1595 (m), 1531 (s), 1416 (w), 1346 (s), 1261 (m) cm ${ }^{-1}$. Anal. Calcd for $\mathrm{C}_{20} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}_{6}$ : C, 60.74; H, 4.34; N, 10.63. Found: C, 60.78; H, 4.36; N, 10.01.
$\boldsymbol{N}$-[(2-(p-Butyldinitrophenyl)-4-quinolyl)carbonyl]-4-(dimethylmethoxysilyl)butanamide (27). ( $p$-Butyldinitrophenyl)quinolinecarboxylic acid ( $\mathbf{1 9}, 2.2 \mathrm{~g}, 5.6 \mathrm{mmol}$ ) was suspended in 40 mL of DCM. The reaction and purification were carried out as described for compound 25: yield $0.6 \mathrm{~g}(20 \%)$ as yellow powder; $\mathrm{mp} 162-165^{\circ} \mathrm{C}$; MS $m / z$ (relative intensity) $539\left(\mathrm{M}^{+}\right), 450,418,392,332,200$ (100); ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}, 250 \mathrm{MHz}\right) \delta 0.17(\mathrm{~s}, 6 \mathrm{H}), 0.74(\mathrm{t}, 2 \mathrm{H}), 1.01(\mathrm{t}, 3 \mathrm{H})$, $1.51-1.85(\mathrm{~m}, 8 \mathrm{H}), 2.98(\mathrm{t}, 2 \mathrm{H}), 3.44(\mathrm{~s}, 3 \mathrm{H}), 3.64(\mathrm{q}, 2 \mathrm{H}), 6.37(\mathrm{~s}$, $1 \mathrm{H}), 7.53(\mathrm{~d}, 1 \mathrm{H}), 7.67(\mathrm{t}, 1 \mathrm{H}), 8.07-8.11(\mathrm{~m}, 2 \mathrm{H}), 8.38-8.59(\mathrm{~m}$, $3 \mathrm{H}) ;{ }^{13} \mathrm{C}-\mathrm{NMR}(\mathrm{DMSO}, 250 \mathrm{MHz}) \delta 0.8,1.1,1.3,14.5,18.4,20.6$, $21.3,22.9,32.3,33.1,49.5,119.1,121.8,123.8,124.9,125.1,125.2$, $125.3,127.6,128.4,130.1,132.2,132.3,133.7,136.7,137.2,137.9$, $139.3,139.6,139.7,139.8,144.8,148.9,149.1,150.6,150.7,156.1$, 166.2, 166.3; IR (KBr disk) v 3271 (s), 2957 (m), 2932 (m), 1641 (m), 1593 (m), 1523 (s), 1340 (m), 1259 (w), 1090 (s) cm ${ }^{-1}$. Anal. Calcd for $\mathrm{C}_{27} \mathrm{H}_{34} \mathrm{~N}_{4} \mathrm{O}_{6} \mathrm{Si}: \mathrm{C}, 60.20 ; \mathrm{H}, 6.37 ; \mathrm{N}, 10.41$. Found: C, 61.11; H, 6.35; N, 11.00.
( $\boldsymbol{p}$-Butyldinitrophenyl)quinoline-Modified Silica Gel (31). Silica gel (3 g) and $N$-[(2-( $p$-butyldinitrophenyl)-4-quinolyl)carbonyl]-4dimethylmethoxysilyl)butanamide ( $27,0.6 \mathrm{~g}, 1.1 \mathrm{mmol}$ ) were suspended in 20 mL of DCM. The reaction and purification were carried out as described for compound 29: yield 3.5 g , coverage $0.2 \mathrm{mmol} / \mathrm{g}$ determined by thermogravimetry $\left(30 \mathrm{~mL} / \mathrm{min} \mathrm{N}_{2}, 1 \mathrm{~h}\right.$ room temperature, $\Delta T=2 \mathrm{~K} / \mathrm{min}$ to $1000^{\circ} \mathrm{C}, 1 \mathrm{~h}$ at $\left.1000^{\circ} \mathrm{C}\right) ; 0.29 \mathrm{mmol} / \mathrm{g}$ determined by elemental analysis; ${ }^{13} \mathrm{C}-\mathrm{CP} / \mathrm{MAS}-\mathrm{NMR}(75.03 \mathrm{MHz}, \mathrm{rf}=10 \mathrm{kHz})$ $\delta-2.8,11.7,21.8,33.3,128.3,135.6,143.6,157.3,168.8 ;{ }^{29} \mathrm{Si}-\mathrm{CP} /$ MAS-NMR ( $59.58 \mathrm{MHz}, \mathrm{rf}=10 \mathrm{kHz}) \delta-111.1,-101.3,12.9$; IR $\left(\mathrm{KBr} /\right.$ silica gel disk) $v 2935,2862,1651,1595,1549 \mathrm{~cm}^{-1}$.
