#### Abstract

High levels of ab initio (MP2, CASSCF, CASPT2N) and density functional (Becke3LYP) theory have been used to assess the homoaromatic character of some strained semibullvalenes. Based on geometric, energetic, and magnetic criteria (magnetic susceptibility exaltations and the nucleus independent chemical shifts, NICS), $C_{s}$ semibullvalene itself is not aromatic, but the $C_{2 v}$ transition state for its Cope rearrangement is highly bishomoaromatic. Appropriate annelations destabilize the $C_{s}$ geometries, and the bishomoaromatic structures are the only minima for several semibullvalenes: 1,5 -methano; 2,8:4,6-bisethano and -bismethano; and 2,8 -monoethano. In contrast, the 4,6 -ethanosemibullvalene is predicted to be localized and not homoaromatic. Inclusion of dynamic electron correlation is very important for computing the geometries and relative energies of the delocalized structures. To aid experimental investigations, the UV and ${ }^{13} \mathrm{C}$ NMR spectra of some of the semibullvalenes have been predicted. Long-wavelength UV absorptions and down-field ${ }^{13} \mathrm{C}$ NMR chemical shifts for $\mathrm{C}_{2,8,4,6}$ are characteristic.

## Introduction

Semibullvalene (1) has intrigued chemists since it was first prepared by Zimmerman et al. ${ }^{1}$ in 1966. The barrier to the degenerate Cope rearrangement in semibullvalene $(4.8 \mathrm{kcal} /$ $\mathrm{mol})^{2}$ is much smaller than that in 1,5 -hexadiene ( $33.5 \mathrm{kcal} /$ $\mathrm{mol})^{3}$ and in bullvalene $(10.9 \mathrm{kcal} / \mathrm{mol}){ }^{4}$ The small barrier in 1 raises the possibility that appropriate substituents might stabilize the delocalized bishomoaromatic transition state (2) to such an extent that it becomes an energy minimum. ${ }^{5-7}$ Dannenberg, ${ }^{5}$ Hoffmann, ${ }^{6}$ and Dewar ${ }^{7}$ suggested that electronwithdrawing groups at $\mathrm{C}_{2,8}, \mathrm{C}_{3,7}$, and $\mathrm{C}_{4,6}$ might stabilize 2 preferentially and eliminate the barrier. However, despite numerous attempts, no experimental realization of a homoaromatic semibullvalene ground state has been achieved. ${ }^{8}$ Taking a different approach, Jiao and Schleyer ${ }^{9}$ recently predicted

[^0]computationally that $\mathbf{2}$ is stabilized, relative to $\mathbf{1}$, by $\mathrm{Li}^{+}$ complexation. The upfield Li chemical shift computed for the $\mathbf{2}-\mathrm{Li}^{+}$complex provided good evidence for the aromaticity of the complex.

1, $C_{s}$

2, $C_{2 v}$

$\mathbf{1}^{1}, C_{s}$

5, $C_{2 v}$

7a, $C_{s}$

$7 \mathrm{~b}, C_{s}$

Annelation strategies, which employ strain to destabilize the $C_{s}$ localized geometry and thus to favor the delocalized $C_{2 v}$ geometry, also have been proposed. ${ }^{10}$ MNDO $(2 \times 2 \mathrm{CI})$ semiempirical calculations by Dannenberg et al. predicted the $C_{2 v}$ structure of 1,5-methanosemibullvalene (3) ${ }^{5}$ to be $9.1 \mathrm{kcal} /$ mol lower in energy than the $C_{s}$ localized form 3a. This preference for $\mathbf{3}$ over 3a was ascribed to the strain reduction

[^1]when the $\mathrm{C}_{2}-\mathrm{C}_{1}-\mathrm{C}_{8}$ angle is opened and also to the electronic interaction of the symmetric combination of the allyl nonbonding orbitals with a cyclopropane orbital of appropriate symmetry. Williams and Kurtz's MNDO and AM1 $(2 \times 2 \mathrm{CI})$ semiempirical calculations indicated that 2,8:4,6-bisethano annelation results in a delocalized $C_{2 v}(4)$ energy minimum, $10.4 \mathrm{kcal} / \mathrm{mol}$ lower in energy (MNDO) than the localized form (4a). ${ }^{11}$

We have now used ab initio and density functional theory (DFT) calculations to compare the geometries, energies, and magnetic properties of the annelated semibullvalenes 3 and 4 with those of the parent $\mathbf{1}$. Other strained semibullvalenes, with bismethano (5), monomethano (6), and monoethano (7) annelations, ${ }^{12}$ also have been examined. We have computed the UV and ${ }^{13} \mathrm{C}$ NMR spectra of the $C_{2 v}$ geometries of $\mathbf{3}$ and $\mathbf{4}$ to aid experimental investigations.

## Computational Methodology

Geometries were optimized at the HF, MP2(fc), Becke3LYP, and $(6,6)$ CASSCF levels by using the $6-31 G^{*}$ basis set with the Gaussian 94 suite of programs. ${ }^{13}$ Vibrational frequencies (at HF/6-31G*, Becke3LYP/6-31G*, and CASSCF/3-21G) were used to characterized the nature of stationary points. ${ }^{14}$ Single-point CASSCF and CASPT2N energies were computed at the CASSCF/6-31G* geometries with the $6-31 G^{*}$ and $6-311 G^{* *}$ basis sets, using the MOLCAS program. ${ }^{15}$ Magnetic susceptibilities and ${ }^{13} \mathrm{C}$ NMR chemical shifts were computed at the Becke3LYP/6-31G* geometries, with Kutzelnigg's IGLO (individual gauge for localized orbitals) method and the standard DZ basis set. ${ }^{16}$ Nucleus independent chemical shifts (NICS) ${ }^{17}$ were computed at GIAO-SCF /6-31G* with Gaussian 94.

## Results and Discussion

Semibullvalene 1. The relative energies between $C_{s}(\mathbf{1})$ and $C_{2 v}(\mathbf{2})$ semibullvalene are summarized in Table 1. At all levels $\mathbf{1}$ is computed to be the energy minimum and $\mathbf{2}$ is found to be the transition state for a boat-like Cope rearrangement. However, HF, CASSCF, and CASPT2N//CASSCF activation enthalpies are significantly ( $>3 \mathrm{kcal} / \mathrm{mol}$ ) higher than the experimental value of $4.8 \pm 0.1 \mathrm{kcal} / \mathrm{mol} .{ }^{2}$ Computational studies of the Cope rearrangement of 1,5 -hexadiene have shown that $(6,6)$ CASSCF calculations do not give correct transition state geometries or energies. ${ }^{18}$ Because dynamic electron correlation is not included, the $(6,6)$ CASSCF tends to overestimate the diradical character of the wave function for the active electrons in the transition states for pericyclic reactions. ${ }^{19}$ The $C_{2 v}$ geometry of semibullvalene (2) was refined at CASPT2N, which includes dynamic electron correlation.

Since it was not possible to optimize the geometry of 2 fully at the CASPT2N level, the same strategy used in the calculations of the Cope rearrangement of 1,5 -hexadiene ${ }^{18}$ was employed. Single-point CASPT2N calculations were performed at various $C_{2 v}$ geometries. These were optimized at the CASSCF level with fixed values of the $\mathrm{C}_{2}-\mathrm{C}_{1}-\mathrm{C}_{8}\left(\mathrm{C}_{4}-\mathrm{C}_{5}-\mathrm{C}_{6}\right)$ angle which controls the interallylic distance, $R$, at each $C_{2 v}$ geometry (Figure 1). The CASPT2N energies were fitted to a quadratic potential; these gave an optimized $\mathrm{C}_{2}-\mathrm{C}_{1}-\mathrm{C}_{8}$ angle for the $C_{2 v}$ geometry (2) of semibullvalene.

The smaller CASPT2N interallylic distance, $R$, in 2 results in stronger interaction between the two allylic fragments. The resulting decrease in the diradical character of $\mathbf{2}$ is reflected in the increase in the ratio in the CASSCF wave function (Table 2) of the squares of the coefficients of the two most important configurations, $\left|\ldots a_{1}{ }^{2} b_{2}{ }^{2} b_{1}{ }^{2}\right\rangle$ and $\left|\ldots a_{1}{ }^{2} b_{2}{ }^{2} a_{2}{ }^{2}\right\rangle$. After CASPT2N geometry optimization, the CASSCF wave function is dominated by the first configuration, which corresponds to the orbital occupancy of a fully delocalized, aromatic species.

As shown in Table 1, the CASPT2N//CASPT2N value of $\Delta H^{\ddagger}$ is closer to experiment than the CASPT2N//CASSCF for

2, while Becke3LYP/6-31G* gives the best agreement with the measured activation enthalpy. However, the correspondence between the Becke3LYP/6-31G* ( $4.5 \mathrm{kcal} / \mathrm{mol}$ ) and the experimental $(4.8 \pm 0.1 \mathrm{kcal} / \mathrm{mol})^{2}$ values is fortuitous, since Becke3LYP calculations with larger basis sets give $\Delta H^{\ddagger}$ values which deviate significantly from experiment.

As shown in Figure 1, the MP2(fc)/6-31G*, Becke3LYP/6$31 \mathrm{G}^{*}$, and $(6,6) \mathrm{CASSCF} / 6-31 \mathrm{G}^{*}$ geometries for $C_{s}$ semibullvalene (1) correspond well with one another. They also agree with the gas-phase electron diffraction structure of $\mathbf{1},{ }^{20}$ except for the large discrepancies in the $\mathrm{C}_{1}-\mathrm{C}_{5}$ and $\mathrm{C}_{2}-\mathrm{C}_{4}$ bond lengths. The experimental $\mathrm{C}_{1}-\mathrm{C}_{5}(1.488 \AA)$ distance is too short and the $\mathrm{C}_{2}-\mathrm{C}_{3}$ bond length $(1.531 \AA$ ) is too long (compare,
e.g., $1.499 \AA$ in cyclopentadiene and $1.498 \AA$ in 1,3-pentadiene $^{21}$ ). Evidently, the lengths assigned to the $\mathrm{C}_{1}-\mathrm{C}_{5}$ and $\mathrm{C}_{2}-$ $\mathrm{C}_{3}$ bonds from the electron diffraction data need to be interchanged; this would result in good agreement with the computed bond lengths.

The distance between vinyl carbons $\mathrm{C}_{4}$ and $\mathrm{C}_{6}$ in $\mathbf{1}$ is 2.410 ((6,6)(CASSCF), 2.327 (MP2(fc)), and $2.364 \AA$ (Becke3LYP/ $6-31 G^{*}$ ). Does a long-range interaction between $C_{4}$ and $C_{6}$ at such large distances result in some degree of homoaromaticity in 1 ?

In order to asses the homoaromaticity of semibullvalene 1, we calculated its magnetic susceptibility exaltation $(\Lambda)$, which is associated uniquely with aromaticity. ${ }^{22,23}$ Generally, $\Lambda$ is defined as the difference between the bulk magnetic susceptibility $\left(\chi_{\mathrm{M}}\right)$ of a compound and the susceptibility $\left(\chi_{\mathrm{M}}{ }^{\prime}\right)$ estimated from an additivity scheme for the same structure, assuming no cyclic delocalization $\left(\Lambda=\chi \mathrm{M}-\chi_{\mathrm{M}}{ }^{\prime}\right)$. ${ }^{22}$ Since magnetic susceptibilities of non-aromatic organic molecules show additive behavior of their constituent groups, values of $\chi_{M^{\prime}}$ can be estimated within an accuracy of a few ppm cgs by increment methods based on group (e.g., $\mathrm{CH}_{3}, \mathrm{CH}_{2}, \mathrm{CH}$, and C ) contributions. Due to ring current effects, aromatic compounds show diamagnetic susceptibility exaltations (more negative values of $\chi_{\mathrm{M}}$ than those expected from the group additivity). The magnetic susceptibilities reported in this paper are derived from IGLO computations.

In addition to magnetic susceptibility exaltations, nucleus independent chemical shifts (NICS) are also simple and efficient probes for aromaticity. ${ }^{17}$ NICS, the negative of the absolute magnetic shielding, can be computed at the ring center (nonweighted mean of the heavy atom coordinates on the ring perimeter) with the Gaussian 94 program. Negative NICS values denote aromaticity ( -11.5 for benzene) and positive NICS values antiaromaticity ( 28.8 for cyclobutadiene). Nonaromatics have negligible NICS ( -2.1 for cyclohexane).

NICS as an indicator of aromaticity agrees well with magnetic susceptibility exaltation and has the advantage of being less dependent on ring size and can be used for individual rings in polycyclic systems. For example, the NICS values for the five-$(-21.5)$ and seven-membered $(-8.3)$ rings of azulene resemble cyclopentadienyl anion (-19.4) and tropylium ion (-8.2). The calculated NICS values for benzocyclobutadiene show that the aromaticity of the six-membered ring $(-4.2)$ is reduced from

that in benzene and the antiaromaticity of the four-membered ring (21.5) is reduced from that in cyclobutadiene. ${ }^{17 \mathrm{a}}$

In order to analyze $C_{s}$ semibullvalene (1), the abnormal magnetic properties of the cyclopropane ring need to be taken into account. ${ }^{24}$ Table 3 summarizes the calculated magnetic susceptibilities of group increments and their reference molecules, as well as magnetic properties for the parent and methylsubstituted cyclopropanes. Cyclopropane is computed to have a magnetic susceptibility exaltation of $\Lambda=-4.2(\Lambda=-5.1$ experimentally ${ }^{22}$ ) and a NICS of -43.3 . However, this large NICS is due in part to the local shielding of the $\mathrm{C}-\mathrm{C}$ bonds, since the ring center in cyclopropane is only $0.44 \AA$ away from the midpoints of these bonds. For comparison, we calculate that the NICS value for planar cyclohexane $\left(D_{6 h}\right)$ is only -1.7 at the ring center, but about -30 at a distance of $0.4 \AA$ from a $\mathrm{C}-\mathrm{C}$ bond. The average contribution of the exalted magnetic susceptibility of three-membered rings is ca. -4.5 ppm cgs.

The IGLO/DZ//Becke3LYP/6-31G* magnetic susceptibility exaltation for $\mathbf{1}$ is only -6.9 ppm cgs (Table 4 ), which is much smaller than that of -13.4 ppm cgs for benzene. ${ }^{25}$ When the

[^5] D.; Kraka, E. J. Am. Chem. Soc. 1985, 107, 5069; 1986, 108, 7467.
contribution of the three-membered ring ( -5.7 ppm cgs for trimethylcyclopropane, Table 3) is deleted, the susceptibility of $\mathbf{1}$ is found not to be exalted. Hence, $C_{s}$ semibullvalene is not aromatic.

The same conclusion is reached from the NICS value for $\mathbf{1}$, which is computed to be -10.3 ppm at the geometric center of the six "active" atoms ( $\mathrm{C}_{2,3,4,6,7,8}$ ). However, this geometric center is only $c a$. $1.1 \AA$ above the three-membered ring. The face of a cyclopropane ring is known to result in shielding, as discussed by Jackman and Sternhell. ${ }^{26}$ To demonstrate this, we calculated a set of NICS values at points above the center of the ring plane in cyclopropane. At distances of 1.0 and $1.1 \AA$, the calculated NICS values of -9.4 and -7.7 ppm are close to the value of -10.3 in $C_{s}$ semibullvalene. This indicates that the cyclopropane unit in semibullvalene is largely responsible for the NICS value and that there is no significant contribution from homoconjugation.

In contrast to $\mathbf{1}$, the $C_{2 v}$ semibullvalene transition state $\mathbf{2}$ is delocalized. The optimized geometries at the Becke3LYP and CASPT2N levels agree well (Figure 1). The $\mathrm{C}-\mathrm{C}$ bond lengths of $1.390 \AA$ are close to those in benzene as well as those in other pericyclic transition state structures. ${ }^{23}$ The interallylic distance, $R \approx 2.1 \AA$, is in the same range as the forming/breaking $\mathrm{C}-\mathrm{C}$ bond lengths in the aromatic transition structure of the parent Cope rearrangement of 1,5 -hexadiene ${ }^{18,27}$ and in many other pericyclic reactions. Thus, the geometry of 2 suggests that it is bishomoaromatic.

The magnetic susceptibility exaltation of -28.8 ppm cgs is larger in magnitude than that in semibullvalene (Table 4), and the large upfield $\mathrm{Li}^{+}$chemical shift of -10.8 ppm in the $C_{2 v}$ $\mathrm{Li}^{+}$complex provides independent evidence of the bishomoaromatic character of $2 .{ }^{9}$ The calculated NICS value of -22.7 at

the geometric center of the active atoms $\left(\mathrm{C}_{2,3,4,6,7,8}\right)$ is the same as found in the aromatic transition state of the boat Cope rearrangement of 1,5 -hexadiene. (The NICS value of the chairlike transition state is $-24.9 \mathrm{ppm} .{ }^{28}$ )

1,5-Methanosemibullvalene (3). The methano bridge in 1,5methanosemibullvalene results in a strained spiropentane moiety in the $C_{s}$ structure (3a), which is absent in the $C_{2 v}$ alternative. Based on MNDO ( $2 \times 2 \mathrm{CI}$ ), Dannenberg et al..$^{5}$ predicated 1,5methanosemibullvalene to have a $C_{2 v}$ equilibrium geometry (3), which was computed to be $9.1 \mathrm{kcal} / \mathrm{mol}$ lower in energy than the $C_{s}$ form (3a). At HF/6-31G*, $\mathbf{3}$ is the transition state for the Cope rearrangement, $12.1 \mathrm{kcal} / \mathrm{mol}$ higher in energy than the $C_{s}$ ground state equilibrium geometry. However, electroncorrelated Becke3LYP/6-31G* and MP2(fc)/6-31G* optimizations lead the $C_{s}$ form to the bishomoaromatic $\mathbf{3}\left(C_{2 v}\right)$. Frequency calculations at Becke3LYP/6-31G* show that $\mathbf{3}$ is an energy minimum. The energy difference between $\mathbf{3}$ and $\mathbf{3 a}$ is only 3.3 (Becke3LYP/6-31G*, using the HF geometry for 3a) and $3.9 \mathrm{kcal} / \mathrm{mol}(\mathrm{CASPT} 2 \mathrm{~N})$ (Table 5).

As shown in Figure 2, the Becke3LYP/6-31G* and MP2-(fc)/6-31G* geometries are similar with interallylic distances of $R=2.279$ and $2.243 \AA$, respectively. The $(6,6)$ CASSCF/ $6-31 \mathrm{G}^{*}$ value of $R=2.615 \AA$ is much larger, and the CASPT2N/6-31G* distance ( $R=2.477 \AA$ ) is intermediate. The large interallylic distances in $\mathbf{3}$ result in considerable diradical character in the wave functions. This is reflected in the relatively small $c_{1}{ }^{2} / c_{2}^{2}$ ratios of 3.3 and 1.7 at the CASPT2N and CASSCF geometries, respectively (Table 2). As discussed above for 2, CASSCF probably overestimates the diradical character of the wave function and, hence, the interallylic distance. On the other hand, because of the importance of the second configuration in the wave function for $\mathbf{3}$, computational methods, such as MP2 and DFT, which are based on a single determinantal wave function, may underestimate the diradical character of the wave function and, hence, the interallylic distance. CASPT2N is most likely to give the most accurate value of $R$ in 3 .

The magnetic properties calculated for $\mathbf{3}$ show it to be a neutral bishomoaromatic. At IGLO/DZ//MP2(fc)/6-31G*, $\mathbf{3}$ is computed to have a very large magnetic susceptibility exaltation of -33.6 ppm cgs. After deleting the estimated cyclopropyl

[^7]

Figure 2. Optimized $C_{s}$ (3a, CASSCF/6-31G* and HF/6-31G*) and $C_{2 v}$ (3, CASSCF/6-31G*, CASPT2N/6-31G* (in bold), MP2(fc)/6$31 G^{*}$, and Becke3LYP/6-31G*) geometries (angstroms and degrees) for 1,5-methanosemibullvalene.
contribution of ca. $-4.5 \mathrm{ppm} \mathrm{cgs}, \mathbf{3}$ still has a large magnetic susceptibility exaltation, comparable to the $\Lambda$ of -28.8 for $C_{2 v}$ semibullvalene (2). The calculated NICS of -22.5 is also nearly the same as that of $2(-22.7)$. Although $1,5-$ methanosemibullvalene (3) is bishomoaromatic, the localized HF/6-31G* $C_{s}$ structure (3a) is not. It is computed to have $\Lambda=-9.9 \mathrm{ppm}$ cgs, less than spiropentane itself, $\Lambda=-11.1 \mathrm{ppm}$ cgs. The NICS value of -7.5 ppm for this localized $C_{s}$ structure (3a) is, as in semibullvalene, largely due to the effect of the threemembered ring (Table 4).

2,8:4,6-Bis(ethano)semibullvalene (4). The ethano bridges in $\mathbf{4 a}$ result in a highly strained bicyclo[2.1.0]pentane moiety in the $C_{s}$ but not in the $C_{2 v}$ geometry (4). At HF/6-31G*, both the localized $C_{s}(\mathbf{4 a})$ minimum and the delocalized $C_{2 v}$ (4) transition state are stationary points. However, at all correlated levels of theory $\mathbf{4}$ is lower in energy and $\mathbf{4 a}$ is not a stationary point (Table 6). Thus, MP2(fc)/6-31G* and Becke3LYP/6$31 \mathrm{G}^{*}$ geometry optimizations of the $C_{s}$ form (4a) lead to the $C_{2 v}$ geometry (4), which is an energy minimum at the latter level. Single-point energy calculations, using the HF/6-31G* geometry of $\mathbf{4 a}$, show $\mathbf{4}$ to be 7.1 (Becke3LYP/6-31G*) and $9.1 \mathrm{kcal} / \mathrm{mol}$ (MP2(fc)/6-31G*) lower in energy than $\mathbf{4 a}$. Similar results were obtained with both $\operatorname{CASSCF}(6,6) / 6-31 \mathrm{G}^{*}$ and CASPT2N/6-31G*. The MNDO energy difference between $\mathbf{4 a}$ and $\mathbf{4}$ is $10.4 \mathrm{kcal} / \mathrm{mol}$. ${ }^{11 \mathrm{a}}$

As shown in Figure 3, the geometries optimized at various levels of theory generally agree well with one another.

Table 6. Calculated Relative Energies ( $\mathrm{kcal} / \mathrm{mol}$ ) of 2,8:4,6-Bis(ethano)semibullvalene in $C_{2 v}(\mathbf{4})$ and $C_{s}(\mathbf{4 a})$

| level | $E_{\text {rel }}{ }^{a}$ |
| :--- | :---: |
| HF/3-21G | 1.2 |
| HF/6-31G* | 3.3 |
| MP2(fc)/6-31G* | $-9.1^{b}$ |
| Becke3LYP/6-31G* | $-7.1^{b}$ |
| (6,6)CASSCF/6-31G* | -3.7 |
| CASPT2N/6-31G* | $-4.3^{c}$ |
| CASPT2N/6-31G* | $-5.9^{d}$ |
| MNDO | $-10.4^{e}$ |

${ }^{a}$ Energy difference between $C_{2 v}$ (4) and $C_{s}$ (4a) 2,8:4,6-bis(ethano)semibullvalene. ${ }^{b}$ Using the $C_{s}$ symmetric HF/6-31G* geometry for single-point energy calculations, since the $C_{s}$ form does not exist at MP2 and Becke3LYP. ${ }^{c}$ Using the $\operatorname{CASSCF}(6,6) / 6-31 G^{*}$ geometry. ${ }^{d}$ Minimum energy geometry predicted using three CASPT2N energies fitted to a quadratic equation (see text), and the CASPT2N/6-31G*// $(6,6) \mathrm{CASSCF} / 6-31 \mathrm{G}^{*} C_{s}$ energy was used for the $E_{\text {rel }}$ calculation. ${ }^{e}$ See ref 11a (the MNDO $(2 \times 2 \mathrm{CI})$ relative energy is the difference of the calculated heats of formation between $\mathbf{4}$ and $\mathbf{4 a}$ ).

However, for $\mathbf{4}$, as for $\mathbf{2}$ and $\mathbf{3}$, CASSCF gives a significantly longer interallylic distance, $R$, than MP2, Becke3LYP, and CASPT2N. The values of $R$ in 4 of $c a .2 .0 \AA$ are slightly smaller than those in the $C_{2 v}$ transition structure (2) for the parent semibullvalene. The allylic $1.396-1.398 \AA \mathrm{C}-\mathrm{C}$ bond lengths in 4 are close to the benzene value ( $1.397 \AA$ ).

Despite the smaller $R$ value at both the CASSCF and CASPT2N optimized geometries, bis(ethano)semibullvalene (4) has a smaller $c_{1}{ }^{2} / c_{2}{ }^{2}$ ratio and more diradical character than 2 (Table 2). This is due to the greater pyramidalization of the terminal allylic carbons in $\mathbf{4}$ away from the concave face (Figure 3 ). The deviation of the angle, $\phi$, between the $\mathrm{C}_{2}-\mathrm{C}_{3}$ bond and the $\mathrm{C}_{1}-\mathrm{C}_{2}-\mathrm{C}_{10}$ plane from $0^{\circ}$ describes the degree of pyramidalization at $\mathrm{C}_{2}, \phi=24.9^{\circ}$ at the CASSCF optimized geometry and $\phi=29.4^{\circ}$ at the CASPT2N optimized geometry. The large degree of pyramidalization of the four equivalent, terminal allylic carbons results in a smaller amount of interallylic bonding in 4 than in $C_{2 v}$ semibullvalene (2), for which $\phi=$ $1.0^{\circ}$ (CASSCF) and $4.3^{\circ}$ (CASPT2N).

As shown in Table 4, the magnetic susceptibility exaltation of $\Lambda=-17.5 \mathrm{ppm}$ cgs in 4 , computed at IGLO/DZ//MP2(fc)/ $6-31 G^{*}$, is larger than the benzene value $\left(\Lambda=-13.4\right.$ (IGLO) ${ }^{23}$ and -13.7 (expt) ${ }^{22}$ ). The bishomoaromatic character of $\mathbf{4}$ is also shown by the calculated NICS of -22.6 ppm . Another demonstration of aromaticity is the upfield Li chemical shift in the lithium cation complex of 4 . In the complex $4-\mathrm{Li}^{+}$, the calculated $\delta \mathrm{Li}^{+}=-9.1$ may be compared with $-6.9(\mathrm{CpLi})$, $-10.8\left(\mathrm{Cp}_{2} \mathrm{Li}^{-}\right){ }^{29}$ and -7.4 (benzene- $\left.\mathrm{Li}^{+}\right)^{23}$ as well as -10.8 for the $C_{2 v}$ complex of $\mathrm{Li}^{+}$with semibullvalene. ${ }^{9}$ In contrast, the magnetic susceptibility exaltation and the NICS of the localized $C_{s} \mathrm{HF} / 6-31 \mathrm{G}^{*}$ 4a structure do not show any significant indication of aromaticity, after correction for the three-membered ring contribution (Table 4).

There are no significant geometric changes in $4-\mathrm{Li}^{+}$relative to 4. The $\mathrm{Li}-\mathrm{C}_{2}$ and $\mathrm{Li}-\mathrm{C}_{3}$ distances, 2.108 and $2.431 \AA$, are comparable to those in the $\mathrm{Li}^{+}$complexed semibullvalene transition structure. ${ }^{9}$ The calculated complexation energy for $4-\mathrm{Li}^{+}$is $46.4 \mathrm{kcal} / \mathrm{mol}$ at Becke3LYP/6-31G*. On the basis of geometric, energetic, and magnetic criteria, 4 is a neutral bishomoaromatic molecule.
$\mathbf{2 , 8 : 4 , 6}-\operatorname{Bis}(m e t h a n o)$ semibullvalene (5). In contrast to the bisethano annelated 4, only the $C_{2 v}$ 2,8:4,6-bis(methano)-

[^8]

Figure 3. Optimized $C_{s}\left(\mathbf{4 a}, \mathrm{CASSCF} / 6-31 \mathrm{G}^{*}\right.$ and HF/6-31G*) and $C_{2 v}\left(4, \mathrm{CASSCF} / 6-31 \mathrm{G}^{*}, \mathrm{CASPT} 2 \mathrm{~N} / 6-31 \mathrm{G}^{*}\right.$ (in bold), MP2(fc)/6$31 \mathrm{G}^{*}$, and Becke3LYP/6-31G*) geometries (angstroms and degrees) for $2,8: 4,6-\mathrm{bis}\left(\right.$ ethano) semibullvalene and for $4-\mathrm{Li}^{+}$(Becke3LYP/631G*).
semibullvalene (5) was optimized at HF/6-31G*, MP2(fc)/6$31 G^{*}$, and Becke3LYP/6-31G*. Frequency analyses (HF and Becke3LYP) show 5 to be an energy minimum. The allylic CC bond lengths (about $1.41 \AA$ ) are close to the benzene value, and the relatively short interallylic separation of $R=1.808-$ $1.811 \AA$ indicates a pronounced neutral homoconjugative interaction in 5 (Figure 4). The computed magnetic susceptibility exaltation of -24.3 ppm cgs (Table 4) in $\mathbf{5}$ is very large, and the calculated upfield $\mathrm{Li}^{+}$chemical shift of -7.9 ppm for the $\mathbf{5}-\mathrm{Li}^{+}$complex (Figure 4) as well as the NICS ( -23.6 ppm ) support the conclusion that $\mathbf{5}$ is bishomoaromatic.

Figure 4. Optimized $C_{2 v}$ (HF/6-31G*, MP2/6-31G*, and Becke3LYP/ $6-31 \mathrm{G}^{*}$ ) geometries (angstroms and degrees) for 2,8:4,6-bis(methano)semibullvalene (5) and for 5-Li+ (Becke3LYP/6-31G*).

Figure 5. Optimized $C_{s}\left(\mathrm{HF} / 6-31 \mathrm{G}^{*}\right.$, MP2(fc)/6-31G* and Becke3LYP/ $6-31 \mathrm{G}^{*}$ ) geometries (angstroms and degrees) for 2,8 -methanosemibullvalene (6).

2,8-Methanosemibullvalene (6). Only one structure (6a) for monomethano annelated semibullvalene was located at HF, MP2(fc), and Becke3LYP, although the initial geometries chosen for optimization ( $\mathbf{6 a}$ and $\mathbf{6 b}$ ) were very different (Figure 5). As shown by the calculated $\mathrm{C}-\mathrm{C}$ bond lengths in Figure 5 , $\mathbf{6 a}$ is localized at $\mathrm{HF} / 6-31 \mathrm{G}^{*}$, but partially delocalized at

Figure 6. Optimized $C_{s}\left(\mathrm{HF} / 6-31 \mathrm{G}^{*}\right.$, MP2(fc)/6-31G*, and Becke3LYP/ $6-31 \mathrm{G}^{*}$ ) geometries (angstroms and degrees) for 2,8 - and 4,6ethanosemibullvalene (7).

MP2(fc) and Becke3LYP. Do these structural features result in partial homoconjugation?

At IGLO//Becke3LYP/6-31G*, $\mathbf{6 a}$ is computed to have a magnetic susceptibility exaltation of -18.0 ppm cgs. However, 6a has a bicyclobutane unit; and 1,3-dimethylbicyclobutane is computed to have an exaltation of -8.2 ppm cgs. After deleting this contribution, the net exaltation of -9.8 for $\mathbf{6 a}$ indicates some aromatic character. In addition, the calculated NICS of -15.2 ppm is larger than the contribution of the three-membered rings, and also supports a modest degree of homoaromaticity of $\mathbf{6 a}$ (Table 4).

2,8- (and 4,6-) Ethanosemibullvalenes (7a and 7b). In contrast to methanosemibullvalene $\mathbf{6}$, but in agreement with earlier semiempirical results, ${ }^{12}$ two ethanosemibullvalene isomers (7a and 7b) are found at HF, MP2(fc), and Becke3LYP. One isomer is $\mathrm{C}_{2}-\mathrm{C}_{8}$ annelated (7a), and the other is $\mathrm{C}_{4}-\mathrm{C}_{6}$ annelated (7b). Both are minima at HF/6-31G* and Becke3LYP/ $6-31 \mathrm{G}^{*}$. However, 7a is 0.6 (MP2(fc)/6-31G*) or $1.0 \mathrm{kcal} /$ mol (Becke3LYP/6-31G*) less stable than 7b after ZPE correction.

At HF/6-31G*, 7a has a localized structure; the $\mathrm{C}_{2}-\mathrm{C}_{8}$ and $\mathrm{C}_{4}-\mathrm{C}_{6}$ distances are 1.588 and $2.409 \AA$, respectively. At MP2-(fc)/6-31G* and at Becke3LYP/6-31G*, $\mathrm{C}_{2}-\mathrm{C}_{8}$ elongates to $1.997 \AA$ and the $\mathrm{C}_{4}-\mathrm{C}_{6}$ shortens to $2.109 \AA$. The $\mathrm{C}_{2}-\mathrm{C}_{3}$ and $\mathrm{C}_{3}-\mathrm{C}_{4}$ bond lengths, which are typical localized values at HF , are delocalized ( 1.395 and $1.393 \AA$ ) at MP2, i.e., nearly the same as in 4. Accordingly, 7a should be considered as homoaromatic based on its geometry. Indeed, the large

Table 7. CASPT2N/6-31G* Vertical UV Absorptions $\lambda(\mathrm{nm})$ for $(6,6)$ CASSCF/6-31G* and CASPT2N/6-31G* Optimized Geometries of Semibullvalene, Methanosemibullvalene, and Bis(ethano)semibullvalene

magnetic susceptibility exaltation ( $-23.2 \mathrm{ppm} \operatorname{cgs}$ ) and NICS $(-22.5 \mathrm{ppm})$ for $7 \mathbf{a}$ confirm its homoaromatic character (Table 4). This agrees with the conclusions of Williams and Kurtz (based on energetic analyses of semiempirical configuration interaction calculations) that 7a is "another example of a neutral homoaromatic ground state hydrocarbon". ${ }^{12}$

In contrast, $\mathbf{7 b}$ has a more localized structure than $\mathbf{7 a}$ at HF , MP2, and Becke3LYP/6-31G*. The $\mathrm{C}_{2}-\mathrm{C}_{8}$ bond length is $1.641 \AA(1.592 \AA$ at HF$)$ and the $\mathrm{C}_{4}-\mathrm{C}_{6}$ separation is $2.133 \AA$. Thus, homoconjugation must be less in 7b than in 7a. The magnetic susceptibility exaltation in $\mathbf{7 b}$ is only -7.5 and the NICS is -12.7 . Both these values are only slightly outside the range for cyclopropanes (Table 3). When the three-ring contributions are removed, no pronounced magnetic susceptibility exaltation of $\mathbf{7 b}$ and its NICS provides evidence for homoconjugation.

Predicted UV and ${ }^{13}$ C NMR Spectra. As an aid to experimentalists, the UV spectra of the semibullvalenes were calculated to help distinguish between the $C_{2 v}$ (open) and $C_{s}$ (closed) geometries. Table 7 lists the wavelengths predicted for different geometries. The $C_{2 v}$ geometries are all expected to absorb at much longer wavelengths that their $C_{s}$ counterparts. However, the very strong dependence of the wavelengths on the interallylic distance, $R$, indicates that accurate prediction of the UV spectra for these molecules would require very accurate values of $R$.

Both strongly allowed excitations for the $C_{2 v}$ species, ${ }^{1} \mathrm{~A}_{1} \rightarrow$ ${ }^{1} \mathrm{~B}_{1}$ and ${ }^{1} \mathrm{~A}_{1} \rightarrow{ }^{1} \mathrm{~B}_{2}$, are computed to shift to the red as the interallylic interactions decrease. In fact, Quast ${ }^{8 b}$ and Williams ${ }^{30}$ have observed reversible thermochroism in semibullvalenes and barbaralanes that are close to being bishomoaromatic. Quast has correlated this phenomenon with a very flat double minimum potential energy surface and an exceptionally low activation barrier to the Cope rearrangement. ${ }^{8 b}$

Although bis(ethano)semibullvalene (4) has a smaller interallylic distance, $R$, than $C_{2 v}$ semibullvalene (2), the UV absorptions are calculated to occur at longer wavelengths in 4

$31 \mathrm{G}^{*}$ geometries.
than in 2. This apparent anomaly is due to the high degree of pyramidalization of the terminal allylic carbons in $\mathbf{4}$ away from the concave face. The reduced orbital overlap between the terminal allylic carbons in 4 results in the calculated red shift of the strongly allowed excitations.

We have computed the ${ }^{13} \mathrm{C}$ NMR chemical shifts for semibullvalene at both the $C_{s}$ equilibrium (1) and $C_{2 v}$ transition state (2) geometries. In Table 8 the computed chemical shifts are compared with the experimental values at $-95^{\circ}$ and $-160^{\circ}$. The IGLO/DZ calculated values for $\mathbf{1}$ agree well with those observed at $-160^{\circ}$. The largest difference between the calculated and observed values is -5.2 ppm for $\mathrm{C}_{4,6}$. As indicated in Table 8, only three signals are observed in the ${ }^{13} \mathrm{C}$ NMR spectrum of $\mathbf{1}$ at $-95^{\circ} \mathrm{C}$. At this temperature the $\mathrm{C}_{3,7}$ chemical shift is the same as at $-160^{\circ} \mathrm{C}$; and the chemical shifts of $\mathrm{C}_{2,8,4,6}$ and of $\mathrm{C}_{1,5}$ at $-95{ }^{\circ} \mathrm{C}$ are very close to the averages of respectively $\mathrm{C}_{2,8}$ and $\mathrm{C}_{4,6}$ as well as $\mathrm{C}_{1}$ and $\mathrm{C}_{5}$ at $-160{ }^{\circ} \mathrm{C}$. This averaging results from the rapid equivalent $C_{s}$ equilibrium geometries ( $\mathbf{1}$ and $\mathbf{1}^{\prime}$ ) at $-95^{\circ} \mathrm{C}$.

In contrast, the computed ${ }^{13} \mathrm{C}$ NMR chemical shifts using the homoaromatic $C_{2 v}$ geometry of $\mathbf{2}$ do not agree satisfactorily overall with the $-95{ }^{\circ} \mathrm{C}$ experimental data. The largest deviation is found for the calculated $\mathrm{C}_{2,8,4,6}$ chemical shifts in 2 ( 96.7 ppm ); these are 11.1 ppm downfield from the average computed for $\mathrm{C}_{2,8}$ and $\mathrm{C}_{4,6}$ in $\mathbf{1}$ ( 85.6 ppm ) and 9.5 ppm downfield from the shifts observed for these four carbons at $-95^{\circ}$. The calculated chemical shift for $\mathrm{C}_{3,7}$ in 2 is 6.4 ppm downfield from that calculated for $\mathrm{C}_{3,7}$ in $\mathbf{1}$ but only 3.7 ppm from that observed at $-95^{\circ}$.

Although a small downfield shift also is computed for $\mathrm{C}_{3,7}$ from the $C_{s}\left(\mathbf{4 a )}\right.$ to the $C_{2 v}$ geometry of bis(ethano)semibullvalene (4), an upfield shift for $\mathrm{C}_{3,7}$ is calculated from the $C_{s}$ (3a) to the $C_{2 v}$ geometry for methanosemibullvalene (3) (Table 9). However, the computed chemical shifts of $\mathrm{C}_{2,8,4,6}$ at the $C_{2 v}$ geometry in both of these annelated semibullvalenes
are 15 ppm downfield from the average of the chemical shifts for the same carbons in the $C_{s}$ geometry. Similarly, the $\mathrm{C}_{2,8}$ and $\mathrm{C}_{4,6}$ chemical shift average is computed to be at significantly lower field in the Becke3LYP geometry for $7 \mathbf{7 a}(99.2 \mathrm{ppm})$ than in the HF geometry both for $7 \mathbf{7 a}(90.8 \mathrm{ppm})$ and for $7 \mathbf{b b}(93.0$ $\mathrm{ppm})$. The ${ }^{13} \mathrm{C}$ chemical shifts for $\mathrm{C}_{2,8}$ and $\mathrm{C}_{4,6}$ in semibullvalenes ( $\mathbf{1}-\mathbf{4}$ and $\mathbf{7}$ ) are sensitive to the geometry and can be used as a structural probe. ${ }^{13} \mathrm{C}$ NMR chemical shifts for $\mathrm{C}_{2,8,4,6}$ in delocalized semibullvalenes are at significantly lower fields than those expected for these carbons in localized semibullvalenes. This should be a useful diagnostic tool.

## Conclusions

On the basis of geometric, energetic, and more importantly magnetic criteria of aromaticity, the $C_{2 v}$ symmetric transition structure (2) for the Cope rearrangement in the parent semibullvalene is bishomoaromatic. In annelated semibullvalenes, such as 1,5-methano (3), 2,8:4,6-bisethano (4), and 2,8:4,6bismethano (5), as well as in the 2,8-ethanosemibullvalene, the bishomoaromatic form is predicted to be lower in energy than the localized structures. The delocalized structures have exalted magnetic susceptibilities and significantly negative values of
the nucleus independent chemical shift (NICS). On the basis of these magnetic criteria, 2,8-methanosemibullvalene has partial aromatic character, and 4,6-ethanosemibullvalene is predicted not to be aromatic. The predicted long-wavelength UV absorptions and down field ${ }^{13} \mathrm{C}$ NMR chemical shifts for $\mathrm{C}_{2,8,4,6}$ are characteristic for the homoaromatic semibullvalenes.

Acknowledgment. This research was supported by the Fonds der Chemischen Industrie, the Deutsche Forschungsgemeinschaft (DFG) and the Stiftung Volkswagenwerk in Erlangen, and the National Science Foundation in Seattle. R.N. gratefully acknowledges the award of a Postdoctoral Fellowship by the Natural Sciences and Engineering Research Council of Canada (NSERC). We thank also Professor David Reingold for stimulating our interest in the possible bishomoaromaticity of 1,5-methanosemibullvalene.

Supporting Information Available: Computed total energies (hartrees) for compounds $\mathbf{1 - 7}$ at various computational levels are summarized in Tables 1-5 (5 pages). See any current masthead page for ordering and Internet access instructions.

Ramamurthy (Tetrahedron Lett. 1996, 37, 5297). Lithium cations in the supercages of zeolites were found to activate and accelerate guest molecules through electrostatic $\pi$-interactions, e.g. the dimerization of benzonorbornadiene. For our further theoretical studies, see refs 21 and 23f.

(d) Kutzelnigg, W.; Fleischer, U.; Schindler, M. NMR, Basic Principles and Progress; Springer Verlag: Berlin, 1990; Vol. 23, p 165. As Kutzelnigg et al. pointed out, IGLO/DZ computed magnetic susceptibilities are generally larger than the experimental values. Moreover, there is often a range of experimental values in the literature due to errors, determinations with different methods, and measurements in gas, liquid, and solid states. Theoretical data have the advantage of uniformity and self-consistency. The errors tend to cancel in exaltation evaluations $(\Lambda)$, which are not far from the values based on the experimental data. For example, the benzene $\Lambda$ value, based on the equation 3 (1,3-butadiene - ethylene) $=$ benzene, is -14.5 (computed) and -14.8 (experimental). Dauben et al. (ref 22) gave -13.7 ppm cgs for benzene based on magnetic susceptibility increment systems using average values derived from many reference compounds. [^4]:    (20) Wang, Y. C.; Bauer, H. S. J. Am. Chem. Soc. 1972, 94, 5651. The authors ascribed the differences between the measured and the semiempirical calculated $\mathrm{C}_{1}-\mathrm{C}_{5}$ and $\mathrm{C}_{2}-\mathrm{C}_{3}$ bond lengths to hyperconjugation between the $\mathrm{C}_{1}-\mathrm{C}_{5}$ bond with the cyclopropyl ring, rather than to an error in assignment. Our MP2(fc)/6-31G* optimized $\mathrm{C}-\mathrm{C}$ distances in substituted cyclopropanes, $1.508 \AA$ in methyl cyclopropane, $1.510 \AA$ in 1,2-cisdimethylcyclopropane, and $1.511 \AA$ in 1,2,3-trimethylcyclopropane, show no significant hyperconjugation effects.
