## Received February 11, 1999

Once somewhat of a curiosity, ${ }^{1}$ the potent Lewis acid, $\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$, has become a compound of practical importance due largely to its role as a cocatalyst for olefin polymerization. ${ }^{2}$ However, information on the analogous aluminum compound, $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$, is much more sparse, ${ }^{3,4}$ although Lewis acid behavior is manifested by the isolation of a THF complex ${ }^{3}$ and a titanium aluminate zwitterion. ${ }^{5}$

One of the noteworthy developments over the past 5-6 years has been the isolation and structural assay of silylium (silicenium) ions, $\left[\mathrm{SiR}_{3}\right]^{+}$, the earliest examples of which feature $\mathrm{R}=\mathrm{Et}^{6}$ or $i$-Pr. ${ }^{7}$ In neither case, however, is the silylium ion "free," being coordinated to toluene when $\mathrm{R}=\mathrm{Et}$ and to one of the bromines of the carboranyl gegenion in the other. ${ }^{8}$ Alanes are isoelectronic with silylium ions; moreover, aluminum is considerably more electropositive than silicon (Pauling electronegativities: Al, 1.61; $\mathrm{Si}, 1.90)$. Hence it occurred to us that $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$ might coordinate to arenes in a fashion similar to $\left[\mathrm{SiEt}_{3}\right]^{+}$.

Equimolar mixtures of $\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$ and $\mathrm{AlMe}_{3}$ were allowed to react anaerobically in either benzene or toluene solutions at 25 ${ }^{\circ} \mathrm{C}$ for 12 h , following which the reaction mixtures were filtered. ${ }^{9}$ Concentration of the filtrates afforded single crystals of $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}{ }^{\circ}$ benzene (1) ${ }^{10}$ and $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$.toluene (2) ${ }^{10}$ suitable for study by X-ray diffraction. ${ }^{11}$ Compounds $\mathbf{1}$ and $\mathbf{2}$ both crystallize in the

Figure 1. Molecular structure of $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3} \cdot$ toluene (2) showing the atomnumbering scheme. Important parameters (with the corresponding parameters for $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3} \cdot$ benzene (1) shown in parentheses): $\mathrm{Al}(1)-$ $\mathrm{C}(1), 1.9836(14) \AA(1.976(7) \AA) ; \mathrm{Al}(1)-\mathrm{C}(7), 1.9812(14) \AA(1.976(6)$ $\AA) ; \mathrm{Al}(1)-\mathrm{C}(13), 1.988(2) \AA(1.986(7) \AA) ; \mathrm{Al}(1)-\mathrm{C}(19), 2.366(2) \AA$ (2.342(6) $\AA) ; ~ \mathrm{C}(1)-\mathrm{Al}(1)-\mathrm{C}(7), 117.18(6)^{\circ}(107.9(3)) ; \mathrm{C}(1)-\mathrm{Al}(1)-$ $\mathrm{C}(13), 108.44(6)^{\circ}\left(117.0(3)^{\circ}\right) ; \mathrm{C}(7)-\mathrm{Al}(1)-\mathrm{C}(13), 114.51(6)^{\circ}(116.8-$ $\left.(3)^{\circ}\right) ; \mathrm{C}(1)-\mathrm{Al}(1)-\mathrm{C}(19), 107.98(6)^{\circ}\left(105.4(3)^{\circ}\right) ; \mathrm{C}(7)-\mathrm{Al}(1)-\mathrm{C}(19)$, $104.39(6)^{\circ}\left(103.9(3)^{\circ}\right) ; \mathrm{C}(13)-\mathrm{Al}(1)-\mathrm{C}(19), 103.12(6)^{\circ}\left(104.2(2)^{\circ}\right)$.
triclinic space group $P \overline{1}$. In the case of $\mathbf{1}$, there is one crystallographically unique molecule of $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$ •benzene per asymmetric unit, along with half a molecule of uncoordinated benzene; the crystalline state of $\mathbf{2}$ is similar but without the extra half molecule of solvent. There are no unusually close intermolecular contacts in $\mathbf{1}$ or $\mathbf{2}$. All the hydrogen atoms were located in the structure of $\mathbf{2}$; for $\mathbf{1}$, the hydrogen atoms were placed in idealized positions. In both $\mathbf{1}$ and $\mathbf{2}$ the arene is coordinated in an $\eta^{1}$ fashion, and the conformations of both molecules are very similar (Figure 1). As in the case of $\left[\mathrm{SiEt}_{3} \cdot \text { } \text { 'oluene }\right]^{+}(\mathbf{3}),{ }^{6}$ the toluene molecule in $\mathbf{2}$ is attached in the para position. The $\mathrm{Al}-\mathrm{C}$ (arene) distances in $\mathbf{1}$ and 2 are 2.342(6) and 2.366(2) $\AA$, respectively, which is $0.28-$ $0.30 \AA$ longer than the sum of covalent radii for these elements. For comparison, the $\mathrm{Si}-\mathrm{C}$ (toluene) distance in $\mathbf{3}$ is $0.24 \AA$ longer than the sum of the Si and C covalent radii. ${ }^{6}$ Use of the Pauling bond length equation ${ }^{12}$ gives an estimated bond order of 0.3 for the $\mathrm{Al}-\mathrm{C}$ (arene) bonds in $\mathbf{1}$ and $\mathbf{2}$. The nature of the arene bonding in $\mathbf{1}$ and $\mathbf{2}$ can be discussed in terms of two canonical forms, $\mathbf{A}$ and $\mathbf{B}$, (Scheme 1) in a manner similar to that reported for $3^{13}$ and the $\mathrm{Ag}^{+}$complex of benzene. ${ }^{14}$ Structure $\mathbf{A}$ is a $\pi$-arene complex ${ }^{15}$ and features an $\mathrm{sp}^{2}$ carbon, while structure $\mathbf{B}$, with an $\mathrm{sp}^{3}$ carbon, is a $\sigma$ complex or Wheland intermediate; ${ }^{16}$ the $\mathrm{Al}-$ $\mathrm{C}-\mathrm{C}_{\text {para }}$ angles for $\mathbf{A}$ and $\mathbf{B}$ are 90 and $125^{\circ}$, respectively. The experimentally determined bond angles of 99.1 and $96.1^{\circ}$ for $\mathbf{1}$ and $\mathbf{2}$, respectively, are therefore closer to those for structure $\mathbf{A}$ which involves idealized $\mathrm{sp}^{2}$ hybridization. A slight perturbation of the arene ring was detectable in the case of $\mathbf{2}$ in the sense that

[^1]
## Scheme 1

the average bond distance for $\mathrm{C}(20)-\mathrm{C}(21)$ and $\mathrm{C}(23)-\mathrm{C}(24)$ (1.386(2) $\AA$ ) is shorter than that for the remaining $\mathrm{C}-\mathrm{C}$ bonds (1.400(2) A).

The interactions with the arene molecules are also evident from the metrical parameters of the $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$ fragment. The sums of bond angles at aluminum are $341.7(3)$ and $340.13(6)^{\circ}$ in $\mathbf{1}$ and $\mathbf{2}$, respectively, thus indicating a significant tetrahedral distortion of the $\mathrm{AlC}_{3}$ trigonal plane ${ }^{17}$ upon complexation. Interestingly, the average $\mathrm{C}-\mathrm{Al}-\mathrm{C}$ bond angles in $\mathbf{1}\left(113.9(3)^{\circ}\right)$ and $2(113.38-$ $\left.(6)^{\circ}\right)$ are identical to that in $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3} \cdot \mathrm{THF}(4)^{3}\left(113.58(10)^{\circ}\right)$, as are the average $\mathrm{Al}-\mathrm{C}$ bond distances within experimental error

[^2](1.979(7), 1.984(2), and 1.995(3) $\AA$ in $\mathbf{1 , 2}$, and 4, respectively). The tetrahedral distortions in $\mathbf{1}$ and $\mathbf{2}$ are also very similar to that in $\mathbf{3}^{6}$ as reflected by the average $\mathrm{C}-\mathrm{Si}-\mathrm{C}$ bond angle of $114^{\circ}$.

The interactions between the arenes and $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$ are sufficiently strong that complexes $\mathbf{1}$ and $\mathbf{2}$ persist in solution. Thus, the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$ solution exhibits a complex pattern in the aromatic $\mathrm{C}-\mathrm{H}$ region (peaks observed at $\delta 6.99$, $7.01,7.05,7.07,7.11$, and 7.13) as expected for an $\eta^{1}$-benzene. Addition of approximately 5 equiv of THF to a solution of $\mathbf{1}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$ results in displacement of the coordinated benzene and formation of the known ${ }^{3}$ complex, 4. Interestingly, the coordinated benzene of $\mathbf{1}$ is not displaced by $\mathrm{Et}_{2} \mathrm{O}$ as evidenced by ${ }^{1} \mathrm{H}$ NMR spectroscopy. These observations imply the sequence of donor strengths, THF $>$ benzene $>\mathrm{Et}_{2} \mathrm{O}$, toward $\mathrm{Al}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$. Complexes $\mathbf{1}$ and $\mathbf{2}$ also retain their integrity in the vapor phase since peaks corresponding to the molecular ions are detectable at $\mathrm{m} / \mathrm{z} 606.3$ (1) and 620.3 (2) in the negative ion CI mass spectra.
