#### Abstract

The electronic absorption spectra and the laser-induced fluorescence spectra of supersonic-jet-cooled 1,3-benzodioxole molecules have been investigated to map out the vibronic energy levels in the $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ electronic excited state. These were used to determine a two-dimensional potential energy surface in terms of the ring-puckering and ring-flapping vibrational coordinates, and the molecule was found to be puckered with a dihedral angle of $22^{\circ}$. The barrier to planarity in the excited state is $264 \mathrm{~cm}^{-1}(3.16 \mathrm{~kJ} / \mathrm{mol})$ as compared to $164 \mathrm{~cm}^{-1}(1.96 \mathrm{~kJ} / \mathrm{mol})$ in the ground state. This increase is attributed to reduced suppression of the anomeric effect by the benzene ring resulting from decreased $\pi$ bonding character in the $S_{1}\left(\pi, \pi^{*}\right)$ state. As expected, the motion along the flapping coordinate is governed by a more shallow potential energy well. Ab initio calculations carried out for both the ground and excited states support the experimental conclusions.

## Introduction

Recently we reported the far-infrared, Raman, and dispersed fluorescence spectra of 1,3-benzodioxole (I) from which we determined the two-dimensional vibrational potential energy surface for the ring-puckering and ring-flapping motions of this molecule in its electronic ground state. ${ }^{1}$ The molecule was found to have a barrier to planarity of $164 \mathrm{~cm}^{-1}(1.96 \mathrm{~kJ} / \mathrm{mol})$ and puckering and flapping angles of $\pm 24^{\circ}$ and $\mp 3^{\circ}$, respectively. The lack of planarity was ascribed to the anomeric effect, which is believed to arise from the interaction between a nonbonded oxygen p orbital and the empty $\sigma^{*}(\mathrm{C}-\mathrm{O})$ orbital on the other oxygen atom. ${ }^{2-5}$ The barrier for 1,3-benzodioxole is considerably less than the $275 \mathrm{~cm}^{-1}(3.29 \mathrm{~kJ} / \mathrm{mol})$ barrier determined ${ }^{6}$ for 1,3-dioxole (II), suggesting a suppression of the anomeric effect by the benzene ring. For 1,3-dioxole the magnitude of the torsional potential energy term for rotation about each $\mathrm{C}-\mathrm{O}$ bond arising from the anomeric effect was calculated to be 25.0 $\mathrm{kJ} / \mathrm{mol}$ whereas for 1,3 -benzodioxole this is only $8.4 \mathrm{~kJ} / \mathrm{mol}$. Ab initio calculations have been carried out for both molecules ${ }^{7,8}$

[^0]and the predicted barriers were in excellent agreement with our experimental findings.

III

IV

To gain more insight into the diminished anomeric effect in 1,3-benzodioxole, we undertook the investigation of this molecule in its $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ electronic excited state. The $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ state for 1,3-benzodioxole is very similar to that for phthalan ${ }^{9}$ (III) and results from an $\mathrm{A}_{2} \rightarrow \mathrm{~A}_{2}$ orbital transition that gives rise to a totally symmetric $A_{1}$ state. In the $S_{0}$ ground state the benzene ring possesses six $\pi$ electrons, but after a $\pi \rightarrow \pi^{*}$ transition the first excited electronic state has five bonding $\pi$ electrons and one antibonding $\pi^{*}$ electron. We therefore wished to determine whether the reduced $\pi$ bonding character of the benzene ring in the $S_{1}\left(\pi, \pi^{*}\right)$ state would decrease the suppression of the anomeric effect and result in a higher barrier to planarity.

We have recently investigated both the ground ${ }^{10,11}$ and excited electronic states ${ }^{9}$ of phthalan, which is similar to 1,3-benzodioxole but lacks the anomeric effect. Phthalan is planar in both states although it possesses a tiny barrier of $35 \mathrm{~cm}^{-1}(0.4 \mathrm{~kJ} /$ mol ) in its ground state. The planarity of phthalan, as well as

[^1]

Figure 1. Fluorescence excitation spectrum (FES) and ultraviolet absorption spectrum of 1,3-benzodioxole. The band origin is at 34789.8 $\mathrm{cm}^{-1}$.
that of the analogous 2,5 -dihydrofuran (IV), ${ }^{12}$ is expected since there are no torsional forces present to pucker the five-membered ring. The methodology developed for the study of the phthalan excited state ${ }^{9}$ was also utilized for the present work. The laserinduced fluorescence spectra of jet-cooled molecules along with the ultraviolet absorption spectra were used to map the ringpuckering and ring-flapping energy levels of 1,3-benzodioxole in its $S_{1}\left(\pi, \pi^{*}\right)$ state. These levels were then used to determine the two-dimensional potential energy surface which defines the conformational energetics of the molecule and therefore provides a clear indication of the magnitude of the anomeric effect.

## Experimental Section

1,3-Benzodioxole was purchased from Aldrich Chemical Co. and purified by vacuum distillation. Fluorescence excitation and dispersed fluorescence spectra were taken using an experimental apparatus described elsewhere. ${ }^{13,14}$ The excitation source was a Nd:YAG pumped dye laser with Rhodamin 590 as the laser dye. The sample was cooled through a pulsed supersonic jet, and spectral lines were detected using a photomultiplier detector.

Ultraviolet absoprtion spectra were recorded on a Bomem DA8.02 spectrometer equipped with a quartz/UV beam splitter, $\mathrm{Si} / \mathrm{UV}$ detector, and deuterium lamp as a source. The sample of 1,3-benzodioxole was contained in a glass cell with quartz windows with pressures ranging from 200 to 500 mTorr . Spectra were acquired at resolutions of 0.5 , 0.25 , and $0.1 \mathrm{~cm}^{-1}$ with acquisitions ranging from 5000 to 7500 scans.

## Results and Discussion

Analysis of Spectra. Figure 1 shows an overview of both the fluorescence excitation spectrum (FES) of the jet-cooled molecules and the ultraviolet absorption spectrum recorded at ambient temperature. The electronic band origin is at 34789.8 $\mathrm{cm}^{-1}$. We have carried out an ab initio calculation at the td-B3LYP/6-31+G(d)//CIS/6-31+G(d) level for the $S_{1}$ state and the transition frequency was calculated to be $36986 \mathrm{~cm}^{-1}$. The jet-cooled molecules for the FES have a vibrational temperature

${ }^{a}$ Relative to the $0_{0}{ }^{0}$ band at $34789.8 \mathrm{~cm}^{-1}$; s strong; m medium; w weak; v very; br broad. ${ }^{b} v_{\mathrm{P}}\left(\mathrm{S}_{0}\right) \rightarrow v_{\mathrm{P}}\left(\mathrm{S}_{1}\right)$; prime indicates $v_{\mathrm{F}}=1$; double prime indicates $v_{\mathrm{F}}=2 .{ }^{c} \mathrm{G}$, from the $\mathrm{S}_{0}$ ground state; H , hot band.
of about 50 K , so only the ground ring-puckering level ( $v_{\mathrm{P}}=$ 0 ) and the first excited level ( $v_{\mathrm{P}}=1$ ), which lies $9.6 \mathrm{~cm}^{-1}$ above the ground state, will be significantly populated. Hence the FES bands originate from only these two states. Table 1 lists the FES bands up to $580 \mathrm{~cm}^{-1}$ along with the corresponding absorption frequencies and assignments. The spectra were recorded numerous times under different jet conditions resulting in colder and warmer spectra thus making it possible to identify hot bands resulting from vibrationally excited states (usually $v_{\mathrm{P}}=1$ ). These are labeled as H in the table and distinguished from the bands originating from the $v_{\mathrm{P}}=0$ ground state $(\mathrm{G})$. The assignments for the bands are also given. Single and double primes on the ring-puckering quantum numbers refer to the ringflapping $v_{\mathrm{F}}=1$ and 2 states, respectively. Figure 2 shows the vibronic levels for the $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ state determined from these spectra and compares them to the vibrational levels previously reported ${ }^{1}$ for the $S_{0}$ electronic ground state. With the molecule assumed to have $C_{2 v}$ symmetry (planar approximation) and to lie in the $x z$ plane, both the ring-puckering and ring-flapping vibrations have $B_{2}$ symmetry. The vibrational coordinates for these modes were defined in our investigation of phthalan. ${ }^{11}$ The ring-puckering is essentially the movement of the $\mathrm{CH}_{2}$ group out of the five-membered ring while the flapping is the bending of the five-membered ring relative to the benzene ring in a butterfly-like motion. Thus in Figure 2 all of the ringpuckering levels with $v_{\mathrm{P}}=$ even for $v_{\mathrm{F}}=0$ or 2 have $\mathrm{A}_{1}$ symmetry whereas the $v_{\mathrm{P}}=$ odd levels have $\mathrm{B}_{2}$ symmetry. When

Figure 2. Energy diagram for the ring-puckering ( $v_{\mathrm{P}}$ ), ring-flapping $\left(v_{\mathrm{F}}\right)$, and $v_{37}$ vibrations of 1,3 -benzodioxole in its ground ( $\mathrm{S}_{0}$ ) and excited $\left(\mathrm{S}_{1}\right)$ electronic states. Single and double primes on the ringpuckering ( $v_{\mathrm{F}}$ ) quantum numbers indicate the $v_{\mathrm{F}}=1$ and 2 states, respectively.
$v_{\mathrm{F}}=1$ or when $v_{37}=1$ ( $v_{37}$ is a $\mathrm{B}_{2}$ vibration, as shown in Table 2), the symmetries are reversed as the $v_{\mathrm{P}}=$ odd levels have $\mathrm{A}_{1}$ symmetry and the $v_{\mathrm{P}}=$ even levels have $\mathrm{B}_{2}$ symmetry. In the spectra (either FES or absorption) most of the observed features with significant intensity are expected from transitions which involve no change in vibrational symmetry $\left(\mathrm{A}_{1} \rightarrow \mathrm{~A}_{1}\right.$ originating from $v_{\mathrm{P}}=0$ or $\mathbf{B}_{2} \rightarrow \mathbf{B}_{2}$ originating from $v_{\mathrm{P}}=1$ ). This is verified in Table 1 where all of the FES bands except the $1 \rightarrow 2$ at $93 \mathrm{~cm}^{-1}$ are of this type. This exception can be explained by the fact that the $v_{\mathrm{P}}=0$ and 1 levels, as will be seen, are below the barrier of this puckered molecule which actually has $C_{s}$ symmetry. Thus, the $1 \rightarrow 2$ transition is actually a symmetric $\mathrm{A}^{\prime} \rightarrow \mathrm{A}^{\prime}$ transition.

The dispersed fluorescence spectra from many of the bands in the FES have also been recorded and these are available elsewhere. ${ }^{1,15}$ These were helpful in determining the symmetries of the $S_{1}$ vibronic levels. For example, the dispersed spectra from the $101.8\left(v_{\mathrm{P}}=2\right)$ and $204.4 \mathrm{~cm}^{-1}\left(v_{\mathrm{P}}=1^{\prime}\right) \mathrm{S}_{1}$ levels, which are both of $A_{1}$ symmetry, showed only transitions to $A_{1}$ bands such as $99.1,236.8$, and $297.8 \mathrm{~cm}^{-1}$ in the $\mathrm{S}_{0}$ ground state. Dispersed spectra from the $B_{2}$ levels such as $162.5 \mathrm{~cm}^{-1}$ $\left(v_{\mathrm{P}}=3\right)$ involved transitions to 9.6 and $157.3 \mathrm{~cm}^{-1}$ as well as to other $\mathrm{B}_{2}$ states. For the phthalan dispersed fluorescence spectra ${ }^{9}$ similar observations were made.

Figure 2 does not show the energy levels associated with the ring-twisting ( $v_{20}$ with quantum number $v_{\mathrm{T}}$ ) vibration which is at $214 \mathrm{~cm}^{-1}$ in the $\mathrm{S}_{0}$ state and predicted to be about $14 \mathrm{~cm}^{-1}$ lower in the $S_{1}$ state by the ab initio calculation (see Table 2). The ring-twisting vibration has $\mathrm{A}_{2}$ symmetry in the $C_{2 v}$ (planar)

approximation. Hence the ring-puckering levels for $v_{\mathrm{T}}=1$ will have either $\mathbf{A}_{2}\left(v_{\mathrm{P}}=\right.$ even $)$ or $\mathbf{B}_{1}\left(v_{\mathrm{P}}=\right.$ odd $)$ symmetry. Since transitions from the $S_{0}$ ground state $\left(A_{1}\right)$ to the $A_{2}$ levels are forbidden and since transitions to the $\mathrm{B}_{1}$ levels give type B bands (with no sharp features), none of these play a role in the interpretation of the spectra. However, transitions to the $v_{\mathrm{T}}=$ 2 state of $\mathrm{A}_{1}$ symmetry in $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$, which is expected to be about $400 \mathrm{~cm}^{-1}$ above the ground vibronic levels, can be seen. The FES becomes considerably more congested above $400 \mathrm{~cm}^{-1}$ and this is due to both the presence of the $v_{\mathrm{T}}=2$ twisting state as well as to energy levels associated with the other vibrations listed in Table 2.

The absorption spectra recorded at ambient temperature arise even from energy levels more than $500 \mathrm{~cm}^{-1}$ above the ground state. For example, a level at $520 \mathrm{~cm}^{-1}$ is still $8 \%$ as populated as the ground state. As shown in our ground state study, ${ }^{1}$ there are seven ring-puckering levels in the ground $\left(v_{\mathrm{F}}=0\right)$ flapping state and another four in the $v_{\mathrm{F}}=1$ state below $520 \mathrm{~cm}^{-1}$. In addition, below $500 \mathrm{~cm}^{-1}$ there are five ring-puckering levels in the first excited $\left(v_{\mathrm{T}}=1\right)$ ring-twisting state and another two in the $v_{\mathrm{T}}=2$ state. The first excited state of $v_{37}$ will have three levels below $520 \mathrm{~cm}^{-1}$. All together 21 energy levels will be at least $8 \%$ as populated as the ground state at ambient temperatures. If states up to $800 \mathrm{~cm}^{-1}$ are considered, where the populations still exceed $2 \%$ of the ground state value, transitions from several dozen additional vibrational states come into play. In addition, there are potentially a hundred or more vibronic levels in the $S_{1}\left(\pi, \pi^{*}\right)$ state to which transitions can readily go so there could be several thousand observable absorption bands in the spectrum of a molecule such as 1,3-benzodioxole. This prospect is made less daunting by the fact that Franck-Condon factors limit many of the transitions and that typically only the totally symmetric transitions, as discussed above, show significant intensity. 1,3-Benzodioxole has $C_{s}$ symmetry, but in its planar approximation it becomes $C_{2 v}$. Since many of the puckering levels lie above the barrier in the ground state and also, as will be seen, in the excited state, the $C_{2 v}$ approximation is suitable for consideration of most of the transitions.

The electronic absorption spectra are very rich, but our detailed knowledge of the ground state energy levels and the symmetries of the transitions make the assignments feasible. This is especially true since the FES readily helps to identify the transitions from the $v_{\mathrm{P}}=0$ and 1 states to more than a dozen of the vibronic levels in the $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ electronic excited state. Figure 3 shows a number of the assigned transitions in the ultraviolet absorption spectrum and Table 3 lists many of the assigned bands. A comprehensive listing of the absorption bands can be found elsewhere. ${ }^{16}$ An important feature in the

[^3]

Figure 3. Absorption spectra and assignments for 1,3-benzodioxole near the band origin.

Figure 4. FES and absorption spectra showing the splitting between the $0-0$ and $1-1$ transitions.
observed spectra is that the $0-0$ and $1-1$ transitions are only $1.4 \mathrm{~cm}^{-1}$ apart, and this is shown in Figure 4. The separation is clear in the absorption spectrum but shows up as a shoulder in the lower resolution FES. While many of the absorption bands in the spectrum have been assigned with confidence with the help of the FES, many others cannot readily be assigned. As discussed above, transitions from numerous excited levels of vibrations other than the ring-puckering and ring-flapping may occur. Each of these possesses combination levels with the puckering, flapping, ring-twisting, etc., which further complicate matters. A portion of the assigned bands no doubt involve the ring-twisting levels where $\mathrm{A}_{2} \rightarrow \mathrm{~A}_{2}$ and $\mathrm{B}_{1} \rightarrow \mathrm{~B}_{1}$ transitions should show significant intensity. A sharp absorption band at $-14.0 \mathrm{~cm}^{-1}$ very likely results from the $v_{\mathrm{T}}=1\left(\mathrm{~S}_{0}\right) \rightarrow v_{\mathrm{T}}=1$ $\left(\mathrm{S}_{1}\right)$ transition, for example. This is also predicted by the ab initio calculation to be at $-14 \mathrm{~cm}^{-1}$, as shown in Table 2.

Calculation of Potential Energy Surface. The determination of the ring-puckering and ring-flapping vibronic levels for the $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ state (Figure 2) makes it possible to calculate the vibrational potential energy surface for these two motions in

the excited state. This was done in a manner similar to that used for the ground-state investigations ${ }^{1}$ using computer programs developed in our previous work. ${ }^{16-19}$ First, an approximate structure was required to carry out the kinetic energy calculation. This was obtained from the ab initio calculation for the $S_{1}$ state and the result is shown in Figure 5 along with the ground-state structure. ${ }^{8}$ The one-dimensional kinetic energy function for the ring-puckering vibration was calculated to be

$$
\begin{align*}
& g_{44}= \\
& 0.0068924-0.053521 x_{1}{ }^{2}+0.18837 x_{1}{ }^{4}-0.61333 x_{1}{ }^{6} \tag{1}
\end{align*}
$$

where $x_{1}$ is the ring-puckering coordinate in $\AA$. An attempt to

${ }^{a} V\left(\mathrm{~cm}^{-1}\right)=\left(1.83 \times 10^{6}\right) x_{1}{ }^{4}-\left(3.15 \times 10^{4}\right) x_{1}{ }^{2}$ for $v_{\mathrm{F}}=0 ; V=$ $\left(2.33 \times 10^{6}\right) x_{1}^{4}-\left(2.99 \times 10^{4}\right) x_{1}^{2}$ for $v_{\mathrm{F}}=1 .{ }^{b} V\left(\mathrm{~cm}^{-1}\right)=(2.641 \times$ $\left.10^{6}\right) x_{1}^{4}-\left(5.284 \times 10^{4}\right) x_{1}^{2}+\left(2.625 \times 10^{3}\right) x_{2}^{4}-\left(6.073 \times 10^{2}\right) x_{2}^{2}+$ $\left(1.618 \times 10^{6}\right) x_{1}^{2} x_{2}^{2}$.
fit the data one-dimensionally resulted in the potential energy function

$$
\begin{equation*}
V\left(\mathrm{~cm}^{-1}\right)=\left(1.83 \times 10^{6}\right) x_{1}^{4}-\left(3.15 \times 10^{4}\right) x_{1}^{2} \tag{2}
\end{equation*}
$$

which has a barrier to planarity of $127 \mathrm{~cm}^{-1}$, but gives poor agreement with the experimentally observed frequencies, as shown in Table 4 as calcd I. This clearly indicates that the ringpuckering cannot be considered independently but couples strongly with the ring-flapping motion. This was also the case in the electronic ground state. ${ }^{1}$

A two-dimensional computation involving both the puckering and flapping was therefore undertaken for the electronic excited state. The kinetic energy functions for the puckering $\left(g_{44}\right)$, flapping ( $g_{55}$ ), and the interaction $\left(g_{45}\right)$ were all calculated in terms of the puckering ( $x_{1}$ ) and flapping ( $x_{2}$ ) coordinates:

$$
\begin{align*}
& g_{44}= \\
& 0.011116-0.10636 x_{1}^{2}+0.53172 x_{1}^{4}-2.58851 x_{1}{ }^{6}- \\
& 0.00071578 x_{2}^{2}+0.00043068 x_{2}^{4}-0.00089162 x_{2}{ }^{6}+ \\
& 0.010416 x_{1}^{2} x_{2}^{2}+0.021844 x_{1} x_{2}^{3}+0.095087 x_{1}^{3} x_{2} \tag{3}
\end{align*}
$$

$g_{55}=$

$$
\begin{gather*}
0.12461-0.14250 x_{1}^{2}+1.01118 x_{1}^{4}-5.64517 x_{1}^{6}- \\
0.12648 x_{2}^{2}+0.048531 x_{2}^{4}-0.022371 x_{2}^{6}+ \\
0.14199 x_{1}^{2} x_{2}^{2}+0.18758 x_{1} x_{2}^{3}+0.81658 x_{1}^{3} x_{2} \tag{4}
\end{gather*}
$$

$g_{45}=$
$-0.022863+0.15608 x_{1}^{2}-0.66490 x_{1}^{4}+3.68901 x_{1}{ }^{6}+$ $0.013019 x_{2}{ }^{2}-0.0032337 x_{2}{ }^{4}+0.0032952 x_{2}{ }^{6}-$ $0.068117 x_{1}^{2} x_{2}^{2}-0.11931 x_{1} x_{2}^{3}-0.58547 x_{1}^{3} x_{2}$

Since the structures for the $S_{0}$ and $S_{1}$ states are fairly similar (as shown in Figure 5), so are the kinetic energy functions. Figures 6-8 in ref 1 show the appearance of these groundstate functions. It should be noted that in ref 1 , the equations for $g_{45}$ and $g_{55}$ for the $\mathrm{S}_{0}$ state were reversed [eq 4 is for $g_{55}$ ]. In addition, there were other errors in signs and exponents. Hence, these are correctly reproduced for the $\mathrm{S}_{0}$ ground state below

Figure 5. Calculated structures for 1,3-benzodioxole in its $S_{0}$ and $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ states. The calculated dihedral angles are $24.2^{\circ}$ and $21.3^{\circ}$, respectively, and the flapping angles are $-2.6^{\circ}$ and $-1.9^{\circ}$. The fivemembered ring is puckered "up" and flapped "down".

& \quad 0.36573 x_{1}^{2} x_{2}^{2}-0.118277 x_{1} x_{2}^{3}-0.131152 x_{1}^{3} x_{2} \tag{8}
\end{align*}
$$

The two-dimensional calculation for the $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ excited state of 1,3-benzodioxole was very successful and resulted in the surface

$$
\begin{align*}
& V\left(\mathrm{~cm}^{-1}\right)= \\
& \left(2.641 \times 10^{6}\right) x_{1}^{4}-\left(5.284 \times 10^{4}\right) x_{1}^{2}+\left(2.625 \times 10^{3}\right) x_{2}^{4}- \\
& \left(6.073 \times 10^{2}\right) x_{2}^{2}+\left(1.618 \times 10^{6}\right) x_{1}^{2} x_{2}^{2} \tag{9}
\end{align*}
$$

which has a barrier to planarity of $264 \mathrm{~cm}^{-1}$. This is shown in Figure 6. The energy minima correspond to $x_{1}= \pm 0.10 \AA$ and puckering dihedral angles of $24^{\circ}$. The energy minima are at $x_{2}$ $=0.0$, reflecting a $0^{\circ}$ flapping angle in the $S_{1}$ state. The observed and calculated (calcd II) frequencies are compared in Table 4. The agreement is excellent, especially considering how much the energy levels are perturbed from "normal" puckering patterns and how much the puckering levels differ in the $v_{\mathrm{F}}=0$ and 1 states. For example, the $0^{\prime}$ and 3 levels at 189.5 and 162.5 interact strongly and their calculated values are very sensitive to the potential energy constants. Hence, the $5.5 \mathrm{~cm}^{-1}$ deviation for the $0-0^{\prime}$ transition is not surprising. It is also not of great concern as it could be better fit with the use of higher order potential energy terms which would not affect the potential energy surface or barrier to planarity to any great extent.

Figure 6. Two-dimensional potential energy surface $\left(\mathrm{cm}^{-1}\right)$ of $1,3-$ benzodioxole in its $\mathrm{S}_{1}\left(\pi, \pi^{*}\right)$ state: $x_{1}=$ ring-puckering; $x_{2}=$ ringflapping.

For the $\mathrm{S}_{0}$ ground state the corresponding potential energy surface was found to be

$$
\begin{align*}
& V\left(\mathrm{~cm}^{-1}\right)=\left(1.929 \times 10^{6}\right) x_{1}^{4}-\left(3.557 \times 10^{4}\right) x_{1}^{2}+ \\
&\left(6.033 \times 10^{3}\right) x_{2}^{2}+(2.806 \times 10)^{5} x_{1}^{2} x_{2}^{2} \tag{10}
\end{align*}
$$

with a barrier to planarity of $164 \mathrm{~cm}^{-1}$ and dihedral angles of puckering of $\pm 21^{\circ}$. [The asymmetric potential energy surface in ref 1 , eq 7 gives $\pm 24^{\circ}$.] In addition to the increased barrier to planarity the most notable other change in the $S_{1}$ surface is the flattening of the surface along the flapping $\left(x_{2}\right)$ coordinate. This is reflected in the decrease in the flapping frequency from 267.2 to $189.5 \mathrm{~cm}^{-1}$ as shown in Figure 2. The ab initio calculations are in good agreement as a shift from 269 to 203 $\mathrm{cm}^{-1}$ is predicted (Table 2). For phthalan ${ }^{9}$ the shift was from 216 to $187 \mathrm{~cm}^{-1}$. For both molecules the decreased $\pi$ character of the benzene ring more readily allows the carbon or oxygen atoms of the five-membered ring to bend out of the plane. The more substantial shift for 1,3-benzodioxole ( $66 \mathrm{~cm}^{-1}$ vs 29 $\mathrm{cm}^{-1}$ ) also reflects the fact that there is significant interaction between the benzene $\pi$ orbitals with the oxygen nonbonded $p$ orbitals.

The large drop in flapping frequency for 1,3-benzodioxole from the $S_{0}$ to $S_{1}$ state also has a pronounced effect on the puckering levels for the $v_{\mathrm{F}}=0$ ground state. In $\mathrm{S}_{0}$ the $v_{\mathrm{P}}=4$ and $1^{\prime}$ levels at 236.8 and $297.8 \mathrm{~cm}^{-1}$ are both of $\mathrm{A}_{1}$ symmetry and have clearly pushed each other apart resulting in a large ( $30.6 \mathrm{~cm}^{-1}$ ) splitting between the $0^{\prime}$ and $1^{\prime}$ levels. For the $\mathrm{S}_{1}$ excited state the splitting between the $0^{\prime}$ and $1^{\prime}$ levels is only $14.9 \mathrm{~cm}^{-1}$ as the $v_{\mathrm{P}}=3$ state of $\mathrm{B}_{2}$ symmetry pushes $0^{\prime}$ up while $v_{\mathrm{P}}=4$ slightly pushes $1^{\prime}$ down. This is confirmed by examination of the mixing in the calculated wave functions for these levels.

Figure 7 compares the potential energy change along the puckering coordinate $\left(x_{1}\right)$ for the $S_{0}$ and $S_{1}$ states. The barrier to planarity has increased significantly from 164 to $264 \mathrm{~cm}^{-1}$, but otherwise the potential energy curves are very similar. The $264 \mathrm{~cm}^{-1}$ barrier for the excited state is very similar to the 275 $\mathrm{cm}^{-1}$ value found for 1,3-dioxole (II) where no benzene ring is present to supress the anomeric effect. This suggests that in the $\mathrm{S}_{1}$ state of 1,3-benzodioxole the distortion of the $\pi$ system considerably reduces the interaction with the oxygen nonbonded orbitals thereby allowing them to participate more strongly in the anomeric effect.

Figure 7. Comparison of the $\mathrm{S}_{0}$ and $\mathrm{S}_{1}(\pi, \pi *)$ vibrational potential energy surfaces along the ring-puckering coordinate ( $x_{1}$ ). The flapping coordinate $x_{2}=0$.

Figure 8. Depiction of the interaction between the benzene $\pi$ system and the oxygen atoms. Only one oxygen nonbonded porbital is shown along with a $\sigma^{*}(\mathrm{C}-\mathrm{O})$ orbital with which the anomeric effect is achieved.

Ab initio calculations for the electronic ground state ${ }^{8}$ of 1,3benzodioxole predict a barrier of $171 \mathrm{~cm}^{-1}$ as compared to the experimental value of $164 \mathrm{~cm}^{-1}$. For the $S_{1}\left(\pi, \pi^{*}\right)$ excited state, our ab initio calculation at the td-B3LPY/6-31+G(d)//CIS/6$31+G(d)$ level predicts a $516 \mathrm{~cm}^{-1}$ barrier, considerably higher than the experimental result. Calculations with CIS/6-31+G(d)// CIS/6-31+G(d) and CIS/6-311+G(2d,p)//CIS/6-31+G* basis sets predict values of 437 and $369 \mathrm{~cm}^{-1}$, respectively. Each of the calculations indicates that in the $S_{1}$ state the anomeric effect is increased as the interaction between the benzene $\pi$ system and the oxygen atoms is decreased.

## Conclusions

This study on 1,3-benzodioxole, just as our previous investigation of phthalan, ${ }^{9}$ demonstrates how the combination of electronic absorption spectroscopy and fluorescence excitation spectroscopy of jet-cooled molecules can be used to very accurately determine the conformationally significant vibronic levels in an electronic excited state. The data thus obtained enabled us to determine the two-dimensional potential energy surface for this molecule in its $S_{1}\left(\pi, \pi^{*}\right)$ excited state in terms of the ring-puckering and ring-flapping vibrational coordinates. The rigidity of 1,3-benzodioxole along the flapping coordinate is considerably reduced in the excited state, but the barrier to planarity along the puckering coordinate is increased to 264 $\mathrm{cm}^{-1}(3.16 \mathrm{~kJ} / \mathrm{mol})$ from $164 \mathrm{~cm}^{-1}(1.96 \mathrm{~kJ} / \mathrm{mol})$ in the ground state. In the ground state there is sufficient interaction between the benzene $\pi$ system and the oxygen atom nonbonded $p$ orbitals
to suppress the anomeric effect that is responsible for the nonplanarity of the five-membered ring. This is depicted in Figure 8. If the benzene-oxygen interaction tries to maintain the oxygen p orbitals aligned with its $\pi$ system, the fivemembered ring cannot readily bend to increase the anomeric interaction that has been ascribed to oxygen p orbital overlap with the $\sigma^{*}(\mathrm{C}-\mathrm{O})$ orbital involving the other oxygen atom. ${ }^{2-6}$ In the $S_{0}$ ground state the benzene-oxygen interaction is significant, as demonstrated by the relatively low barrier to planarity of $164 \mathrm{~cm}^{-1}$. Following a $\pi \rightarrow \pi^{*}$ transition, however,
the degree of $\pi$ bonding on the benzene ring has been reduced and the interaction with the oxygen atoms is decreased. This then allows the oxygen p orbitals to participate to a greater degree in the anomeric effect and thus to bend the fivemembered ring to a more puckered configuration.
