# A Planar Tetracoordinate Carbon and Unusual Bonding in an Organodimetallic Propynylidene Complex Arising from Double C-H Activation of an Allene Ligand 

Jui-Hsien Huang, Jeffrey J. Luci, Ting-Yu Lee, Dale C. Swenson, Jan H. Jensen,* and Louis Messerle*<br>Department of Chemistry, The University of Iowa, Iowa City, Iowa 52242

Received March 12, 2002 ; E-mail: lou-messerle@uiowa.edu

Alkylidenes are important in organic and organometallic chemistries and cosmochemistry because of their structures, reactivities, and interstellar/circumstellar presence. Propynylidene 1 (HCCCH) is the simplest alkynylcarbene that, along with abundant interstellar ${ }^{1-3}$ cyclopropenylidene 2 and propadienylidene 3 (Scheme 1), has attracted substantial interest. Propynylidene is a proposed intermediate in interstellar $\mathrm{C}_{3} \mathrm{H}^{4,5}$ formation since photoisomerization between $\mathbf{1}, \mathbf{2}$, and $\mathbf{3}$ is facile.

Experimental ${ }^{6-9}$ and recent computational ${ }^{5,9,10}$ studies show that $\mathbf{1}$ has a triplet ground state and a $C_{2}$ geometry, although that geometry is only $0.1-0.2 \mathrm{kcal} \mathrm{mol}^{-1}$ lower than the $C_{s}$ and $C_{2 v}$ geometries. ${ }^{5}$ The conformational potential energy of singlet 1 (ca. $11 \mathrm{kcal} \mathrm{mol}^{-1}$ above the triplet ${ }^{10}$ ) is similarly flat. ${ }^{10-12}$

Among the successes of organotransition metal chemistry is the stabilization of reactive species. Double $\mathrm{C}-\mathrm{H}$ activation of allene represents a possible route to a $\mathrm{C}_{3} \mathrm{H}_{2}$ ligand, which could complex in several ways (Chart $1, \mathrm{M}=$ metal and ancillary ligands). Examples are known ${ }^{13-17}$ for many of these, but not for $\mathbf{1 2}$ or 13.

Here, we report preparation and characterization of a propynylidene organodimetallic. MO calculations on free (MCSCF) and complexed (RHF, DFT) HCCCH were used to understand the bonding of this new organometallic ligand.

The reaction of allene with the $\mathrm{d}^{2}-\mathrm{d}^{2}$ organoditantalum(III) ( $\eta$ $\left.\mathrm{C}_{5} \mathrm{Me}_{4} \mathrm{R}\right)_{2} \mathrm{Ta}_{2}(\mu-\mathrm{X})_{4}\left(\mathrm{R}=\mathrm{Me}\left(\mathrm{Cp}^{*}\right), \mathrm{Et} ; \mathrm{X}=\mathrm{Cl}, \mathrm{Br}\right)^{18}$ leads to complexation ${ }^{19}$ rather than $\mathrm{C}-\mathrm{H}$ activation. ${ }^{20}$ An agostic $\mathrm{C}-\mathrm{H}$ interaction in $\left(\eta-\mathrm{C}_{5} \mathrm{Me}_{4} \mathrm{R}\right)_{2} \mathrm{Ta}_{2}(\mu-\mathrm{X}) \mathrm{X}_{3}\left(\mu-\eta^{1}, \eta^{3}-\mathrm{C}_{3} \mathrm{H}_{4}\right)(\mathbf{1 4})$ may be antecedent to $\mathrm{C}-\mathrm{H}$ activation. Reduction of $\mathbf{1 4}$ gives $\mathbf{1 5}$ (eq 1),

via a double $1,3-\mathrm{C}-\mathrm{H}$ activation, with $\mathrm{C}_{3} \mathrm{H}_{2}$ and two $\mu$-hydride ligands instead of an allenyl hydride. ${ }^{21}$ Product $\mathbf{1 5}$ is dinuclear by mass spectrometry, with high symmetry based on NMR spectroscopies. $\mathrm{C}_{3} \mathrm{H}_{2}$ ligand NMR data $(\mathrm{X}=\mathrm{Cl})$ are unusual, with downfield resonances for the hydrogen ( $\delta 11.4$ ), terminal carbons ( $\delta 215.6,{ }^{1} J_{\mathrm{CH}}=189$ ), and central carbon ( $\delta 161.4$ ). These data, consistent with $\mathrm{Ta}=\mathrm{C}$ bonding to the HCCCH carbons, could not differentiate complexed 1 (i.e., 12) from 2 ( 9 or 10).

Single-crystal diffractometry ${ }^{22}$ revealed a $\mu$-propynylidene coplanar with two Ta atoms (Figure 1). Selected bond distances and angles are listed in Table 1. The molecule has crystallographically imposed $C_{2}$ symmetry. The HCCCH ligand is related to 1 rather than the $\mu$-alkylidene form (13). The HCCCH hydrogen was refined, but $\mathrm{H}(1)$ was not as this led to an unacceptably small $\mathrm{Ta}(1)-\mathrm{H}(1)$ distance. The $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(2 \mathrm{~A})$ angle $\left(153.7(13)^{\circ}\right)$ is smaller than

Scheme 1

Chart 1

Table 1. Experimental and Calculated Distances and Angles for $15^{a}$

| distance $(\AA)$ /angle (deg) | experimental | theory |
| :--- | :--- | :--- |
| $\mathrm{Ta}(1)-\mathrm{Ta}(1 \mathrm{~A})$ | $2.8817(7)$ | 2.930 |
| $\mathrm{Ta}(1)-\mathrm{C}(1)$ | $2.194(9)$ | 2.203 |
| $\mathrm{Ta}(1)-\mathrm{C}(2)$ | $1.970(9)$ | 1.966 |
| $\mathrm{C}(1)-\mathrm{C}(2)$ | $1.370(8)$ | 1.385 |
| $\mathrm{Ta}(1)-\mathrm{H}(1)-\mathrm{Ta}(1 \mathrm{~A})$ | 97.9 | $100.0,99.8$ |
| $\mathrm{Ta}(1)-\mathrm{C}(1)-\mathrm{Ta}(1 \mathrm{~A})$ | $82.1(4)$ | 83.4 |
| $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(2 \mathrm{~A})$ | $153.7(13)$ | 144.5 |
| $\mathrm{C}(1)-\mathrm{C}(2)-\mathrm{H}(2)$ | $139(5)$ | 128.7 |
| $\mathrm{Ta}(1)-\mathrm{C}(1)-\mathrm{C}(2)$ | $62.1(5)$ | $61.6,61.6$ |
| $\mathrm{Ta}(1)-\mathrm{C}(2)-\mathrm{C}(1)$ | $79.9(6)$ | $80.3,80.1$ |
| $\mathrm{Ta}(1)-\mathrm{C}(2)-\mathrm{H}(2)$ | $139(5)$ | $151.0,151.2$ |

${ }^{a}$ No $C_{2}$ symmetry was imposed in the calculations. Transformation for experimentally equivalent atoms: $\mathrm{A},-x,-y,-z+3 / 2$.

Figure 1. Thermal ellipsoid plot of 15.
that predicted ${ }^{9}\left(172-4^{\circ}\right)$ for $\mathbf{1}$, and the HCCCH ligand adopts a curved conformation that maximizes $\mathrm{Ta}-\mathrm{C}$ bonding. The $\mathrm{C}(2)-$ $C(1)$ distance $(1.370(8) \AA)$ is longer than that in allene $(1.308 \AA)^{23}$ or predicted for $\mathbf{1}(1.273-1.279 \AA) .{ }^{9}$ Tetracoordinate $\mathrm{C}(1)$ is planar,

Figure 2. MOLDEN ${ }^{27}$ plots of key MOs for $\mathbf{1 5}$ (with $\mathrm{C}_{5} \mathrm{H}_{5}$ in lieu of $\left.\mathrm{Cp}^{*}\right)$ : (A) three-center, two-electron $\mathrm{Ta}-\mathrm{C}(1)-\mathrm{Ta}^{\prime}$ bond; (B) $\mathrm{Ta}-\mathrm{C}(2)$ $\sigma$-bond; $(\mathbf{C})$ orthogonal views of $\mathrm{Ta}-\mathrm{C}(2)-\mathrm{C}(1) \pi$-bond.
with surrounding angles totaling $360^{\circ}$; $\mathrm{C}(2)$ is planar (angle sum $358^{\circ}$ ), so $\mathrm{H}(2)$ is coplanar with the C and Ta atoms. The $\mathrm{Ta}-\mathrm{Ta}$ distance is in the single bond range, suggesting a $\mathrm{d}^{1}-\mathrm{d}^{1}, \mathrm{Ta}(\mathrm{IV})_{2}$ complex and a formally dianionic HCCCH. However, the $\mathrm{Ta}-\mathrm{C}(2)$ distance is consistent with a $\mathrm{Ta}=\mathrm{C}$ double bond, leading to an allenediylidene $(4-) / \mathrm{Ta}(\mathrm{V})_{2}$ description with no $\mathrm{Ta}-\mathrm{Ta}$ bonding. We turned to calculations in order to address this ambiguity.

Geometry optimizations of $\mathbf{1 5}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right.$ in place of $\left.\mathrm{Cp}^{*}\right)$ were performed at the RHF/SBK(d) level. ${ }^{24,25}$ Selected parameters are listed in Table 1, and agreement with the solid-state structure is quite good. Important localized ${ }^{26} \mathrm{MOs}$ are displayed in Figure 2. The MOs in Figures 2A and 2C are best described as three-center, two-electron $\sigma$ and $\pi$ bonds connecting $\mathrm{Ta}-\mathrm{C}(1)-\mathrm{Ta}$ and $\mathrm{Ta}-$ $\mathrm{C}(2)-\mathrm{C}(1)$, respectively. There is no net $\mathrm{Ta}-\mathrm{Ta}$ bonding MO, and the total electron density shows no evidence of a $\mathrm{Ta}-\mathrm{Ta}$ bond. This suggests the following formal bonding picture with a threecenter, two-electron bridge bond.

Organodimetallics with planar tetracoordinate $\mu$-carbon atoms are rare. ${ }^{28} \mathrm{~A}$ three-center, two-electron bond involving a carbonbased lone pair has been examined theoretically. ${ }^{29}$

When conceptually removed from 15 in the observed geometry, triplet HCCCH is $56.7 \mathrm{kcal} \mathrm{mol}^{-1}$ higher than the W -shaped $C_{2}$ minimum. ${ }^{30}$ The two structures are connected by a steepest descent path with no barrier, indicating that the $C_{2}$ geometry is the closest minimum on the triplet PES.

We have examined the reactivity of this new organometallic functional group. Surprisingly for a complex with valence electron count $<18$ and $\mathrm{Ta}=\mathrm{C}$ bonding, $\mathbf{1 5}$ is unreactive $\left(<65^{\circ}, \mathrm{C}_{6} \mathrm{D}_{6}\right)$ toward $\mathrm{H}_{2}, \mathrm{CO}$, and $\mathrm{C}_{2} \mathrm{H}_{4}$. This nonreactivity may reflect the lack of a suitable LUMO for nucleophilic attack. The products from reactions with electrophiles are being characterized. We have not yet found conditions that liberate HCCCH from 15, although photolysis appears promising.

While conversion of $\mathbf{1 4}$ to $\mathbf{1 5}$ is a formal double $\mathrm{C}-\mathrm{H}$ activation, the mechanism remains to be examined by crossover experiments. We have yet to observe reaction intermediate(s) (e.g., an allenyl hydride) during the $\mathrm{C}-\mathrm{H}$ activation.

These results show that propynylidene can be generated as an organodimetallic ligand in solution by double $\mathrm{C}-\mathrm{H}$ activation of allene and that it can adopt a curved structure. Calculations show that the HCCCH ligand is best described as an allenediyl-idene(4-) with a planar tetracoordinate carbon.

Acknowledgment. The authors thank N. Goroff for helpful discussions on the cosmochemical significance of $\mathrm{C}_{3} \mathrm{H}_{2}$. The diffractometer and NMR spectrometer were purchased in part with National Science Foundation (CHE85-07623) and Department of Energy (DE-FG05-89ER75503) funds.

(30) Relative energy was calculated at the MCQDPT/cc-pVDZ level [Nakano, H. J. Chem. Phys. 1993, 99, 7983] via GAMESS. The curved geometry is optimized (RHF/SBK(d)) while the $C_{2}$ geometry is the $\operatorname{MCSCF}(5,4)$ / cc-pVDZ minimum. Significant nonintegral occupation numbers for some MOs demonstrated the need for MCSCF. The intrinsic reaction coordinate (IRC) was performed at the $\operatorname{MCSCF}(5,4) / \mathrm{cc}-\mathrm{pVDZ}$ level.
