Mechanism of Palladium-Catalyzed Diene Cyclization/ Hydrosilylation: Direct Observation of Intramolecular Carbometalation

Nicholas S. Perch and Ross A. Widenhoefer*

Contribution from the P. M. Gross Chemical Laboratory, Duke University, Durham, North Carolina 27708-0346

Received January 12, 2004; E-mail: rwidenho@chem.duke.edu

Abstract: The results of kinetic, deuterium-labeling, and low-temperature NMR studies have established a mechanism for the palladium-catalyzed cyclization/hydrosilylation of dimethyl diallylmalonate (1) with triethylsilane involving rapid, irreversible conversion of the palladium silyl complex [(phen)Pd(SiEt₃)(NCAr)]+ $[BAr_4]^ [Ar = 3,5-C_6H_3(CF_3)_2]$ (4b) and 1 to the palladium 5-hexenyl chelate complex {(phen)Pd[η^1, η^2 -CH(CH₂SiEt₃)CH₂C(CO₂Me)₂CH₂CH=CH₂]⁺ [BAr₄]⁻ (5), followed by intramolecular carbometalation of 5

to form the palladium cyclopentylmethyl complex trans-{(phen)Pd[CH2CHCH2C(CO2Me)2CH2CHCH2SiEt3]-(NCAr)⁺ $[BAr_4]^-$ (6), and associative silulation of 6 to release 3 and regenerate 4b.

Introduction

Functionalized carbocycles are among the most common structural components of naturally occurring and/or biologically active molecules and, for this reason, considerable effort has been directed toward the development of general and efficient methods for the synthesis of functionalized carbocycles.¹ Transition metal-catalyzed methods have demonstrated particular utility in the synthesis of functionalized carbocycles due to the ability of transition metal complexes to facilitate transformations not possible using traditional approaches and due to the high levels of selectivity, efficiency, and atom-economy often realized via transition metal catalysis.² Notable among these transition metal-catalyzed carbocyclization processes are the cyclization/ addition of envnes,^{3,4} dienes,^{5,6} divnes,^{7,8} or bis(dienes)⁹ with a hydrosilane, hydrostannane, or bimetallic reagent to form a carbocycle that possesses one or more functionalized C-X bonds that can be manipulated in a subsequent transformation.¹⁰

We have developed a number of effective transition metalcatalyzed cyclization/addition protocols,4,6,8 including the palladium-catalyzed cyclization/hydrosilylation of functionalized 1,6-dienes to form silvlated cyclopentanes.⁶ For example, reaction of dimethyl diallylmalonate (1) and HSiEt₃ catalyzed by $[(\text{phen})\text{Pd}(\text{Me})(\text{OEt}_2)]^+$ $[\text{BAr}_4]^ [\text{Ar} = 3,5\text{-}\text{C}_6\text{H}_3(\text{CF}_3)_2]$ (2a) (5 mol %) at 0 °C for 5 min formed silvlated cyclopentane 3 in 92% isolated yield with \geq 98% trans selectivity (Scheme 1).¹¹ This protocol displayed good functional group compatibility, high regio- and diastereoselectivity, and low air- and moisturesensitivity and was applicable to the synthesis of cyclohexanes, fused and tethered polycyclic compounds, and nitrogen heterocycles.⁶ A notable extension of this chemistry was the asymmetric cyclization/hydrosilylation of 1,6-dienes catalyzed by enantiomerically pure palladium pyridine-oxazoline complexes to form silvlated cyclopentanes with up to 95% ee.⁶

In contrast to our thorough exploration of the scope, limitations, and extensions of palladium-catalyzed diene cyclization/ hydrosilylation,⁶ we have generated little information regarding the mechanism of this transformation, nor has detailed information regarding the mechanism of a late transition metal-catalyzed cyclization/addition process been reported. Although the mechanisms of zirconocene-catalyzed diene carboalumination¹² and

Scheme 1

carbomagnesiation have been reported,13 these systems are poor models for synthetically significant late transition metalcatalyzed cyclization/addition processes, including palladiumcatalyzed diene cyclization/hydrosilylation. Rather, our mechanistic understanding of palladium-catalyzed diene cyclization/ hydrosilylation has been restricted to insights gleaned from our synthetic investigations⁶ or from the mechanistic studies of related palladium-catalyzed transformations including olefin hydrosilylation,¹⁴ dimerization,¹⁵ and copolymerization¹⁶ and diene cycloisomerization.¹⁷ Due to the synthetic potential of palladium-catalyzed diene cyclization/hydrosilylation specifically, and late transition metal-catalyzed cyclization/addition in general, we initiated a study directed toward elucidating the mechanism of palladium-catalyzed diene cyclization/hydrosilylation. Here we report a full account of our mechanistic investigation of the cyclization/hydrosilylation of 1 and HSiEt₃ to form 3 catalyzed by $[(phen)Pd(Me)(NCAr)]^+ [BAr_4]^- [Ar$ $= 3.5 - C_6 H_3 (CF_3)_2$ (2b). This study has produced both the first detailed mechanism of a late transition metal-catalyzed cyclization/addition process and the first direct observation of the β -migratory insertion of a coordinated olefin into the M–C bond of a transition metal alkyl olefin chelate complex (intramolecular carbometalation).18

Results

Brookhart has shown that the cationic palladium etherate complex 2a reacts rapidly with HSiEt₃ at -80 °C to form the palladium silvl silane complex [(phen)Pd(SiEt₃)(HSiEt₃)]⁺ $[BAr_4]^ [Ar = 3,5-C_6H_3(CF_3)_2]$ (4a), which reacts with simple olefins to form palladium silvl olefin complexes.¹⁴ On the basis of these results, we initiated our mechanistic investigation of palladium-catalyzed diene cyclization/hydrosilylation with the stoichiometric reaction of dimethyl diallylmalonate (1) and the palladium silvl complex [(phen)Pd(SiEt₃)(NCAr)]⁺ [BAr₄]⁻ [Ar $= 3,5-C_6H_3(CF_3)_2$ (4b). Complex 4b was employed in preference to 4a to avoid potential complications arising from the silane ligand of 4a and due to the enhanced thermal stability of 4b relative to that of 4a. Silvl complex 4b was generated in quantitative yield (101 \pm 10% by ¹H NMR) by treatment of a CD₂Cl₂ solution of **2b** (42 mM) with triethylsilane (1 equiv) at -81 °C for 5 min (Scheme 2). Conversion of 2b to 4b was established by the disappearance of the Pd-CH₃ resonance of

2b (δ 1.26) and by the appearance of the Pd-SiEt₃ resonances of **4b** [δ 0.97 (q), 1.06 (t), J = 7.5 Hz] and free methane (δ 0.21) in the ¹H NMR spectrum.

Formation of Alkyl Olefin Chelate Complex 5. Addition of 1 (1 equiv) to a solution of 4b (42 mM) at -62 °C led to rapid ($t_{1/2} \le 5$ min) formation of the palladium 5-hexenyl chelate complex {(phen)Pd[η^1, η^2 -CH(CH₂SiEt₃)CH₂C(CO₂Me)₂CH₂- $CH=CH_2$]⁺ [BAr₄]⁻ (5) in 84 ± 10% yield by ¹H NMR spectroscopy as a single diastereomer (Scheme 2).¹⁹ Thermally sensitive 5 was characterized in solution at -62 °C by NMR spectroscopy. The ¹H NMR spectrum of 5 displayed a oneproton multiplet at δ 2.66 (Pd-CH), a one proton doublet of doublets at δ 1.23 (J = 3, 13 Hz, $-CHHSiEt_3$), and a oneproton triplet at δ 1.11 (J = 13 Hz, $-CHHSiEt_3$), which together established insertion of an olefin of 1 into the Pd-Si bond of 4b. Olefin coordination was supported by the large difference of the ¹H NMR chemical shifts of the olefinic protons of 5 [δ 6.41 (dddd, J = 4, 8, 9, 16 Hz), 5.44 (d, $J_{cis} = 9$ Hz), and 4.22 (d, $J_{\text{trans}} = 16 \text{ Hz}$)] relative to the corresponding olefinic resonances of uncomplexed 1 [δ 5.53, 5.09, and 5.06]. Coordination of the pendant olefin of 5 was further supported by the large difference of the ¹³C NMR chemical shifts of the olefinic carbons of the ¹³C-labeled isotopomer {(phen)Pd[η^1, η^2 - $^{13}CH(^{13}CH_2SiEt_3)^{13}CH_2C(CO_2Me)_2^{13}CH_2^{13}CH=^{13}CH_2]$ + [BAr₄] $(5^{-13}C_6)$ (δ 103.7 and 87.5) relative to the corresponding olefinic resonances of uncomplexed 1-1,2,3,5,6,7- $^{13}C_6$ (δ 131.4 and 119.7) and by the much smaller C=C coupling constant of **5**-¹³C₆ ($J_{C=C} = 47$ Hz) relative to free **1**-1,2,3,5,6,7-¹³C₆ ($J_{C=C}$ = 69 Hz).²⁰

⁽¹⁹⁾ Neither formation of byproducts nor decomposition was observed in any of these transformations. The formation of 6 in 93% yield from 3 suggests that the yield for the conversion of 2 to 4 was higher than indicated by ¹H NMR.

⁽²⁰⁾ Benn, R.; Rufiñska, A. J. Organomet. Chem. 1982, 238, C27.

Figure 1. ¹H NOESY spectrum of **5**. Cross-peaks corresponding to through-space interactions between the ortho phenanthroline proton at δ 8.35 with the internal (a) and trans-terminal olefinic protons (b), and between the ortho phenanthroline proton at δ 8.71 with the Pd–CH methine (c), and the –CHHSiEt₃ methylene protons (d) are denoted.

Low-temperature ¹H-¹H NOESY analysis of 5 revealed through-space interactions between the ortho phenanthroline proton at δ 8.35 with both the internal (δ 6.41) and transterminal olefinic protons (δ 5.44) (Figure 1). These interactions established orientation of the olefin approximately perpendicular to the coordination plane, as is typically observed with nonchelated square planar Pd(II) and Pt(II) olefin complexes.²¹ NOESY analysis of 5 also revealed through-space interactions between the ortho phenanthroline proton at δ 8.71 with both the methine proton of the palladium-bound alkyl group (δ 2.66) and with one of the diastereotopic methylene protons of the exocyclic triethylsilylmethyl group (δ 1.11) (Figure 1). Analysis of molecular models indicated that interaction of the ortho phenanthroline proton with both the Pd-CH and -CHHSiEt₃ protons can be achieved only if the triethylsilylmethyl group adopts an axial or pseudoaxial position with respect to the hexenyl chelate. Although this result was initially somewhat surprising, further analysis of molecular models revealed that in an equatorial or pseudoequatorial position, the triethylsilylmethyl group experiences a pronounced, unfavorable interaction

6334 J. AM. CHEM. SOC.
VOL. 126, NO. 20, 2004

with the phenanthroline ligand. Given the axial orientation of the triethylsilylmethyl group, **5** likely adopts a boatlike conformation to avoid unfavorable 1,3-diaxial interaction between the triethylsilylmethyl group and one of the carbomethoxy groups.²²

To probe for reversible formation of **5**, a solution of **5** (25 mM) that contained NCAr (25 mM) was treated with 4,4dicarbomethoxy-2,6-dideuterio-1,7-heptadiene (1-2,6- d_2) (50 mM) and monitored periodically by ¹H NMR spectroscopy. Formation of neither free **1** nor **5**- d_2 was detected after 90 min at -80 °C and 30 min at -60 °C, which established irreversible conversion of **4b** to **5** under these conditions. In a similar manner, ¹H NMR analysis of solutions of **5** that contained either NCAr (42 mM) or both NCAr (42 mM) and **1** (42 mM) at -62 °C revealed no evidence for displacement of the chelated olefin of **5** to form the 5-hexenyl species **5-L** (L = NCAr, **1**) (Scheme 3). The failure to form detectable quantities of **5-L** under these

⁽²¹⁾ Albright, T. A.; Hoffmann, R.; Thibeault, J. C.; Thorn, D. L. J. Am. Chem. Soc. 1979, 101, 3801 and ref 23 therein.

⁽²²⁾ We cannot rule out a structure for 5 in which the α -(triethylsilyl)methyl group and the terminus of the complexed olefin have a cis relationship. However, if this were the case, cis to trans isomerization must precede conversion of 5 to 6, and this isomerization must be fast relative to the conversion of 5 to 6 as the rate of conversion of 5 to 6 was independent of [NCAr].

5

Scheme 3

5-L (L = NCAr or 1)

Table 1. First-Order Rate Constants for the Conversion of 5 ($[5]_0$ = 42 mM) to 6 in CD₂Cl₂ as a Function of Temperature

entry	temp (°C)	$(10^4)k_{5\to 6}(s^{-1})$
1	-62	0.288 ± 0.022
2	-55	0.711 ± 0.002
3	-51	1.41 ± 0.01
4	-41	5.04 ± 0.05
5	-41	4.35 ± 0.03
6	-41	6.33 ± 0.04
7	-30	27.2 ± 0.5

conditions is not surprising, given the likelihood of a large negative entropy of reaction for the conversion of **5** to **5-L**, ^{16,23,24} and does not rule out rapid and reversible formation of **5-L**. To the contrary, given the extreme facility of the associative exchange of ethylene and α -olefins at cationic square planar palladium complexes, ^{14–16,25,26} reversible formation of **5-L** from **5** in the presence of **1** or NCAr appears likely. Because the relative stereochemistry of **5** is lost upon olefin displacement, the diastereoselective formation of **5** is likely under thermodynamic control.

Formation of Palladium Cyclopentylmethyl Complex 6. Warming a solution of palladium alkyl olefin chelate complex 5 at -41 °C for 2 h led to β -migratory insertion and formation of the palladium cyclopentylmethyl complex *trans*-{(phen)Pd-

[CH₂CHCH₂C(CO₂Me)₂CH₂CHCH₂SiEt₃](NCAr)}⁺ [BAr₄]⁻ (6) in 96 ± 10% yield by ¹H NMR spectroscopy as a single diastereomer (Scheme 2). Thermally sensitive 6 was characterized in solution by ¹H- and ¹³C NMR spectroscopy at -41 °C. The ¹H NMR spectrum of 6 displayed two one-proton multiplets at δ 1.67 and 1.80, assigned to the cyclopentyl methine protons, and two one-proton doublets of doublets at δ 2.09 (J = 8, 11 Hz) and 2.52 (J = 4, 8 Hz), assigned to the palladium-bound methylene group, which together established β -migratory insertion and cyclopentyl ring formation. The trans stereochemistry of 6 was established by the exclusive formation of *trans*-3 from reaction of 6 with HSiEt₃, given the likelihood that conversion of 5 to 6 is irreversible under reaction conditions (see below).

Disappearance of 5 (~42 mM) at -41 °C in the presence of NCAr (~42 mM) obeyed first-order kinetics to >3 half-lives with a rate constant of $k = 5.2 \pm 0.8 \times 10^{-4} \text{ s}^{-1}$; $\Delta G^{\ddagger}_{232 \text{ K}} = 16.9 \pm 0.1$ kcal mol⁻¹, as the average of three separate experiments (Table 1, entries 4–6; Figure 2). Because NCAr was completely consumed during the conversion of 5 to 6, the first-order decay of 5 established the zero-order dependence of the rate of conversion of 5 to 6 on [NCAr]. First-order rate

- (26) Rix, F. C.; Brookhart, M.; White, P. S. J. Am. Chem. Soc. 1996, 118, 2436.

Figure 2. First-order plot for the conversion of 5 ($[5]_0 = 42 \text{ mM}$) to 6 at -41 °C in CD₂Cl₂ that contained NCAr (42 mM).

Figure 3. Eyring plot for the conversion of 5 to 6 over the temperature range -30 to -62 °C.

constants for the conversion of **5** to **6** were determined as a function of temperature from -30 to -62 °C (Table 1). An Eyring plot of these data provided the activation parameters for the conversion of **5** to **6** (Figure 3): $\Delta H^{\ddagger} = 13.5 \pm 0.6$ kcal mol⁻¹ and $\Delta S^{\ddagger} = -15 \pm 2$ eu.

Conversion of 6 to Palladium Carbonyl Chelate Complex 7. Warming a solution of palladium cyclopentylmethyl complex 6 at $-9 \,^{\circ}$ C for 2 h in the absence of silane led to rearrangement and formation of the thermally stable cyclopentyl carbonyl chelate complex *trans,trans*-{(phen)Pd[CHCH(Me)CH(CH₂-<u>SiEt_3)CH_2C(COOMe)(COOMe)]}</u>+ [BAr₄]⁻ (7) in 110 ± 10% yield (93 ± 10% from **4b**) by ¹H NMR spectroscopy as a single

diastereomer (Scheme 2).¹⁹ Complex **7** was subsequently isolated in 49% yield from the preparative-scale reaction of an equimolar mixture of [(phen)Pd(Me)(NCCH₃)]⁺ [BAr₄]⁻ (**2c**), **1**, and HSiEt₃ and was characterized by spectroscopy and elemental analysis. The ¹H NMR spectrum of **7** displayed a one-proton doublet at δ 2.47 (J = 10.5 Hz, Pd–CH) and a threeproton doublet at δ 1.20 (J = 6.5 Hz, CH–CH₃), which together established migration of the palladium atom from the exocyclic methylene carbon to the C(2) carbon atom of the cyclopentyl ring. The relative stereochemistry of **7** was established by degradation with DSiEt₃ (see below) and by comparison of the ¹H NMR spectrum of **7** to that of the structurally characterized

analogue trans, trans-{(phen)Pd[CHCH(Me)CH(Et)CH₂C-

(COOMe)(COOMe)] $^+$ [BAr₄]⁻ (**7a**).¹⁷ Conversion of palladium cyclopentylmethyl complex **6** to palladium carbonyl chelate complex **7** did not obey first-order kinetics (Figure S1), presumably due to the increasing concentration of free NCAr with increasing conversion.

Silylation of Palladium Alkyl Complexes. Reaction of palladium cyclopentylmethyl complex 6 (32 mM) with triethvlsilane (50 mM) at -41 °C for 10 min led to complete ($\geq 95\%$) consumption of 6 to form a 1:1 mixture of the silvlated carbocycle 3 and palladium silyl complex 4b as the exclusive products in 90 \pm 10% yield by ¹H NMR spectroscopy (Scheme 2). Assuming that silvlation of 6 obeyed a second-order rate law, as was established for the silvlation of 7 (see below), we estimate a lower limit for the second-order rate constant for the silulation of **6** of $k \ge 0.19$ M⁻¹ s⁻¹ at -41 °C ($\Delta G^{\ddagger} \le 14.2$ kcal mol⁻¹).²⁷ Although the extreme facility of this transformation precluded detailed kinetic analysis, silylation of 6 was inhibited by excess nitrile, and reaction of 6 (40 mM) and HSiEt₃ (50 mM) in the presence of CD₃CN (0.5 M) required \geq 30 min to reach completion at 0 °C. Reaction of 6 with DSiEt₃ at -41°C formed 1,1-dicarbomethoxy-3-deuteriomethyl-4-triethysilylmethylcyclopentane $(3-d_1)$ as the exclusive isotopomer as determined by ¹³C NMR and GC/MS analysis (Scheme 4). Selective incorporation of deuterium into the exocyclic methyl group of 3- d_1 was established by the 1:1:1 triplet at δ 17.1 (J = 19.1 Hz, isotopic shift = 300 ppb), corresponding to the exocyclic -CH₂D group in the ¹³C NMR spectrum. Noteworthy is that catalytic cyclization/deuteriosilylation of 1 with DSiEt₃ also formed $3-d_1$ as the exclusive isotopomer (Scheme 4).

Treatment of palladium alkyl olefin chelate complex **5** with HSiEt₃ formed none of the product resulting from silylation of the Pd–C bond of **5** but instead formed silylated carbocycle **3** as the exclusive organic product (Scheme 2). This result is in accord with the failure to form significant amounts ($\leq 2\%$) of silylated uncyclized products in the palladium-catalyzed cyclization/hydrosilylation of **1** and HSiEt₃.¹¹ Reaction of **5** (43 mM) with HSiEt₃ (128 mM) to form **3** at -51 °C obeyed first-order kinetics to >2 half-lives with a rate constant of $k = 1.59 \pm 0.01 \times 10^{-4} \text{ s}^{-1}$ (Figure S2), which does not differ significantly from the first-order rate constant for the conversion of **5** to **6** at -51 °C ($k = 1.41 \pm 0.01 \times 10^{-4} \text{ s}^{-1}$) (Table 1,

Table 2. Silane Concentration Dependence of the Rate of Conversion of 7 ([7] $_0 = 20-36$ mM) to 3 at -14 °C in CD₂Cl₂

Figure 4. Plot of k_{obs} versus silane concentration for the reaction of 7 ([7]₀ = 20-36 mM) and HSiEt₃ in CD₂Cl₂ at -14 °C.

Scheme 5

entry 3). These observations are consistent with conversion of **5** to **3** via rate-limiting conversion of **5** to **6** followed by rapid silylation of **6** to give **3**.

In contrast to the facile silvlation of cyclopentylmethyl complex 6, reaction of palladium carbonyl chelate complex 7 (30 mM) with HSiEt₃ (40 mM) to form 3 as the exclusive organic product required 2 h at room temperature (Scheme 2). Conversion of 7 (36 mM) to 3 at -14 °C in the presence of a large excess of HSiEt₃ (0.36 M) obeyed pseudo-first-order kinetics through \geq 4 half-lives with an observed rate constant of $k_{obs} = 1.33 \pm 0.01 \times 10^{-4} \text{ s}^{-1}$ (Table 2, entry 3, Figure S3). To determine the dependence of the rate of the silvlation of 7 on silane concentration, pseudo-first-order rate constants for reaction of 7 and HSiEt₃ at -14 °C were determined as a function of silane concentration from 0.18 to 0.93 M (Table 2). A linear plot of k_{obs} versus [HSiEt₃] established the first-order dependence of the rate of the conversion of 7 to 3 on silane concentration and the second-order rate law: rate = k[7][HSiEt₃], where $k = 3.3 \pm 0.3 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$ at 22 °C ($\Delta G^{\dagger}_{259\text{K}} =$ $22.0 \pm 0.1 \text{ kcal mol}^{-1}$) (Figure 4).

Treatment of **7** with DSiEt₃ (0.42 M) at room temperature for 2 h led to formation of *trans,trans*-1,1-dicarbomethoxy-2deuterio-4-(triethylsilylmethyl)-3-methylcyclopentane (**3**- d_1 ') in 46% yield with 83% isotopic purity as determined by GC/MS analysis (Scheme 5). The regiochemistry of **3**- d_1 ' was established by the 1:1:1 triplet at δ 42.0 ($J_{CD} = 20.6$ Hz, isotopic shift = 320 ppb), assigned to the C(2) carbon atom of the cyclopentane

^{(27) (}a) The rate constant k for the silylation of **6** was calculated for the rate law: rate = $k[\mathbf{6}][\mathrm{HSiEt}_3]$ employing the following equation: $kt = \{1/([\mathrm{HSiEt}_3]_0 - [\mathbf{6}]_0)\} \times \ln\{[(\mathbf{6}]_0 \times [\mathrm{HSiEt}_3]_0/([\mathrm{HSiEt}_3]_0 \times [\mathbf{6}]_l)\}$, where t = 600 s, $[\mathbf{6}]_0 = 0.032$ M, $|\mathrm{HSiEt}_3]_0 = 0.0016$ M (95% conversion) [HSiEt_3]_t = 0.0166 M (95% conversion).^{27b} (b) Frost, A. ring in the ¹³C NMR spectrum. The relative stereochemistry of $3-d_1'$ was established by the absence of the doublet of doublets at δ 2.48 in the ¹H NMR spectrum of $3-d_1'$ that had been previously assigned to the methylene proton trans to the methyl group via two-dimensional ¹H-¹H COSY and NOESY spectroscopy of unlabeled 3.

Two sets of experiments were performed to probe the effect of silane structure on the silvl-incorporation step in the catalytic cyclization/hydrosilylation of 1. In one set of experiments, 1 was treated with a catalytic amount of 2b and an excess of an equimolar mixture of HSiEt₃ (5 equiv) and HSiMe₂R (R = Et, *n*-octyl, OSiMe₃, or Ph) (5 equiv) in 1,2-dichloroethane (DCE) to form a mixture of carbocycles 3 and 3a, 3b, 3c, or 3d, respectively (Table 3, entries 1-4). These data revealed that the extent of silane incorporation increased with both the decreasing steric bulk and increasing electron density of the silane. As examples, palladium-catalyzed reaction of 1 with a 1:1 mixture of HSiEt₃ and HSiMe₂Et formed a 1:5.9 mixture of carbocycles 3:3a (Table 3, entry 1), while reaction of 1 with a 1:1 mixture of HSiEt₃ and the small, electron-rich pentamethyldisiloxane formed a 1:48 mixture of carbocycles 3:3c (Table 3, entry 3). To better quantify the effect of the electron density of the silane on the silvl-incorporation step in the catalytic cyclization/hydrosilylation of 1, 1 was treated with a catalytic amount of 2b and a mixture of HSiMe₂Ph (5 equiv) and $HSiMe_2(4-C_6H_4R)$ (R = NMe₂, OMe, F, or CF₃) (5 equiv) to form a mixture of carbocycles 3d and 3e, 3f, 3g, or 3h, respectively (Table 3, entries 5-8). The corresponding plot of log 3d:3e-3h versus the Hammett σ -parameter was roughly linear with a slope of $\rho = -1.1$ (Figure 5).²⁸

Kinetics of Catalytic Cyclization/Hydrosilylation. We sought to establish the resting state and rate behavior of the catalytic cyclization/hydrosilylation of **1** and HSiEt₃ under conditions that approximated the relative and absolute concentrations of diene and silane employed in preparative-scale reactions. To this end, a solution of **1** ($[1]_0 = 85 \text{ mM}$), HSiEt₃ ([HSiEt₃]₀ = 0.16 M),²⁹ NCAr ([NCAr] = 42 mM), and a catalytic amount of **2b** ($[2b]_0 = 12 \text{ mM}$) in CD₂Cl₂ was monitored periodically by ¹H NMR spectroscopy at -41 °C.

Figure 5. Plot of log 3d:3e-3h formed in the reaction of 1 with a 1:1 mixture of HSiMe₂Ph (3d) and HSiMe₂(4-C₆H₄R) [R = NMe₂ (3e), OMe (3f), F (3g), and CF₃ (3h)] catalyzed by 2b versus the Hammet σ -parameter.²⁸

Throughout complete conversion of **1** to **3**, alkyl olefin chelate complex **5** was the only palladium species detected by ¹H NMR spectroscopy. A plot of [**1**] versus time was linear to 3 halflives with a pseudo-zero-order rate constant of $k_{obs} = 8.3 \pm 0.6 \times 10^{-6}$ M s⁻¹, determined as the average of three separate experiments (Figure 6, Table 4, entries 1–3).²⁹ The linear decay of [**1**] versus time established the zero-order dependence of the rate of conversion of **1** to **3** on [**1**] over the range 85–~6 mM and on [HSiEt₃] over the range 0.16–~0.08 M. However, saturation kinetics were not maintained at lower silane concentration, and a plot of [**1**] versus time for reaction of **1** ([**1**]₀ =

^{(28) (}a) Exner, O. in *Correlation Analysis in Chemistry; Recent Advances*; Chapman, N. B., Shorter, J., Eds.; Plenum: New York, 1978; pp 439– 540. (b) Matsui, K.; Hepler, *Can. J. Chem.* **1974**, *52*, 2906.

⁽²⁹⁾ The principle source of error in our kinetic measurements was determination of catalyst concentration, which stemmed from the difficulty in accurately weighing 2b into the NMR tube. Efforts to improve the accuracy of these measurements by employing stock solutions of 2b were unsuccessful due to the short lifetime of 2b in solution at ambient temperature.

Figure 7. Plot of k_{obs} versus catalyst loading for the reaction of 1 ([1]₀ = 85 mM) and HSiEt₃ ([HSiEt₃]₀ = 0.16 M) catalyzed by **2b** ([**2b**]₀ = 12 mM) to form 3 at -41 °C in CD₂Cl₂.

85 mM) and HSiEt₃ ([HSiEt₃]₀ = 90 mM) catalyzed by **2b** $([2b]_0 = 12 \text{ mM})$ at -41 °C displayed pronounced positive curvature (Figure 6).²⁹ Point-by-point analysis of concentration versus time plots for catalytic cyclization/hydrosilylation of 1 $([1]_0 = 85 \text{ mM})$ at low silane concentration $([HSiEt_3]_0 = 90)$ mM) indicated that the reaction rate decreased \sim 50% as the silane concentration decreased from 90 to \sim 5 mM (95% conversion).

The rate of palladium-catalyzed cyclization/hydrosilylation under saturation conditions was independent of nitrile concentration over the range of 12-74 mM (Table 4, entries 1-5). To determine the dependence of the rate of catalytic cyclization/ hydrosilylation on catalyst concentration, pseudo-zero-order rate constants for reaction of 1 and HSiEt₃ ([HSiEt₃]₀ = 0.16 M) catalyzed by 2b at -41 °C were determined as a function of precatalyst concentration (Table 4, entries 1-3, 6-9). A linear plot of k_{obs} vs $[2b]_0$ over the range of 0–25 mM established the first-order dependence of the rate of catalytic cyclization/ hydrosilylation on precatalyst concentration and overall the firstorder rate law under saturation conditions: rate $= k_{sat}[2b]$, where $k_{\text{sat}} = 7.74 \pm 0.06 \times 10^{-4} \text{ s}^{-1}; \Delta G^{\ddagger} = 16.8 \pm 0.1 \text{ kcal mol}^{-1}$ (Figure 7). Pseudo-zero-order rate constants for catalytic cyclization/hydrosilylation of 1 and HSiEt₃ ([HSiEt₃] $_0 = 0.16$ M) were measured as a function of temperature from -57 to -25°C (Table 4, entries 1–3, and 10–13). An Eyring plot of the corresponding first-order rate constants provided the activation parameters: $\Delta H^{\ddagger} = 13 \pm 1 \text{ kcal mol}^{-1} \text{ and } \Delta S^{\ddagger} = -15 \pm 3 \text{ eu}$ (Figure 8).

Discussion

Mechanism of Cyclization/Hydrosilylation. The mechanism for the cyclization/hydrosilylation of 1 and HSiEt₃ catalyzed by 2b to form 3 depicted in Scheme 6 is consistent with all of our experimental observations. Silvlation of precatalyst 2b with triethylsilane forms the observed palladium silyl complex 4b. Displacement of the nitrile ligand of 4b with one of the double bonds of 1 would form the unobserved palladium silvl olefin species I. β -Migratory insertion of the coordinated olefin into the Pd-Si bond of I to form the coordinatively unsaturated palladium alkyl intermediate II followed by coordination of the pendant olefin of **II** would form the observed alkyl olefin chelate complex 5. β -Migratory insertion of the coordinated olefin into the Pd-C bond of 5 to generate the coordinately unsaturated palladium cyclopentylmethyl complex III followed by ligand

Figure 8. Eyring plot for the reaction of $1 ([1]_0 = 85 \text{ mM})$ and HSiEt₃ $([HSiEt_3]_0 = 0.16 \text{ M})$ catalyzed by **2b** $([2b]_0 = 12 \text{ mM})$ over the temperature range -57 to -25 °C.

capture with NCAr would form the observed palladium cyclopentylmethyl complex 6. Associative silvlation of 6 via the palladium-silane intermediate IV would release carbocycle 3 and regenerate the palladium silvl complex 4b. Because cationic, coordinatively unsaturated palladium,³⁰⁻³² rhodium,³³ and cobalt^{34,35} alkyl olefin complexes are stabilized by dynamic β -agostic interactions, coordinately unsaturated complexes II and **III** are also likely stabilized by β -agostic interactions.

Conversion of 4b to 5. The failure of alkyl olefin chelate complex 5 to exchange with 1-2,6- d_2 at -60 °C established irreversible conversion of 4b and 1 to 5, which requires irreversibility in one or more of the microscopic steps in the conversion of 4b to 5. Because the nitrile ligand of catalyst precursor 2b exchanges rapidly with a double bond of 1 at -80°C ($K_{eq} \approx 0.25$),³⁶ it is likely that conversion of **4b** to **I** is also rapid and reversible. Although β -migratory insertion of ethylene into the Pd-Si bond of the cationic palladium silvl ethylene complex [(phen)Pd(SiEt₃)(H₂C=CH₂)]⁺ is reversible at -60°C,¹⁴ we propose that rapid, exothermic coordination of the pendant olefin of II to form 5 renders both the conversion of I to II and the conversion of II to 5 irreversible. We estimate that conversion of **II** to **5** is exothermic by ~ 12 kcal mol⁻¹ on the basis of DFT calculations for displacement of the β -agostic interaction of the palladium ethyl complex [(H2PCH=CHPH2)- $PdCH_2CH_3$ ⁺ (8) with ethylene to form [(H₂PCH=CHPH₂)Pd- $(H_2C=CH_2)(CH_2CH_3)$]⁺ (9).³⁷ Irreversible silvlpalladation of 1 with 4b is further supported by the irreversible hydropalladation of $\mathbf{1}$ with a cationic palladium hydride complex.¹⁷

Alkyl Olefin Chelate Complexes. β -Migratory insertion of the coordinated olefin into the M-C bond of a transition metal alkyl olefin chelate complex is often invoked as the key C-C bond-forming process in transition metal-mediated and -catalyzed cyclization protocols.² Although β -migratory insertion of

Scheme 6

the coordinated olefin into the M-C bond of a nonchelated transition metal alkyl olefin complex has been directly observed. 15,16,25,26,30,31,34,35,38,39 olefin β -migratory insertion of the coordinated olefin into the M-C bond of a transition metal alkyl olefin chelate complex has not. Rather, the majority of wellcharacterized transition metal alkyl olefin chelate complexes decompose via β -hydride elimination without undergoing β -migratory insertion.⁴⁰ For example, the nickel 4-pentenyl chelate complex CpNi[η^1 , η^2 -CH₂CH₂CH₂CH=CH₂] (Cp = C₅H₅) isomerized at 70 °C in THF to form a mixture of π -allyl complexes CpNi(η^3 -CH₃CHCHCHCH₃) and CpNi(η^3 -CH₂-CHCHCH₂CH₃) (Scheme 7).⁴¹ Similarly, the cationic platinum 4-pentenyl chelate complex $[(PMe_3)_2Pt(\eta^1,\eta^2-CH_2CMe_2CH_2 CH=CH_2)$]⁺ [BF₄]⁻ rearranged at -10 °C to form a mixture of the isomeric π -allyl complexes [(PMe_3)_2Pt(η^3 -CMe_2CH-CHMe)]⁺ [BF₄]⁻ and [(PMe₃)₂Pt(η^3 -CH₂CMeCHMeCH₂CH₃)]⁺ [BF₄]^{-.42} The neutral rhodium 3-butenyl bis(phosphine) carbonyl chelate complex $(PPh_3)_2Rh(CO)[\eta^1,\eta^2-CH_2C(Ph)_2CH=CH_2]$ decomposed at 50 °C to form 1,1-diphenyl-1,3-butadiene in 44% yield.43 Although treatment of the palladium norbornyl chloride Scheme 8

dimer 10 with dppe [dppe = bis(diphenylphosphino)ethane] led to rapid β -migratory insertion to form the palladium tricyclo- $[2.2.1.0^{0,0}]$ heptyl complex **11**, the reactive alkyl olefin phosphine complex was not detected (Scheme 8).44

In two cases, β -migratory insertion of the olefin into the M–C bond of a 4-pentenyl chelate complex has been directly implicated through scrambling of deuterium atoms between the C(1) and C(3) carbon atoms of the pentenyl ligand. For example, Hallenbeck and Casey have reported that the yttrocene 4-pentenyl chelate complex $Cp_2^*Y[\eta^1, \eta^2-CD_2CH_2CH_2CH=CD_2]$ (12- $1,1,5,5-d_4$) (Cp* = C₅Me₅) isomerized over 2 h at -78 °C to form a 1:1 mixture of **12**-1,1,5,5-*d*₄ and **12**-3,3,5,5-*d*₄ (Scheme 9).⁴⁵ Likewise, Flood has reported that thermolysis of the platinum 4-pentenyl chelate complex (dmpe)Pt[η^1, η^2 -CD₂CMe₂- $CH_2CH=CH_2$] (13-1,1- d_2) [dmpe = bis(dimethylphosphino)ethane] at 125 °C for 8 h formed a 1:1 mixture of $13-1,1-d_2$ and 13-3,3-d2.46 However, in neither case was the cyclobutylmethyl intermediate observed and, for this reason, conversion of 5 to 6 represents the first direct observation of the β -migratory insertion of the coordinated olefin into the M-C bond of an alkyl olefin chelate complex. Furthermore, due to the substantial

Scheme 9

strain that accompanies cyclobutyl ring formation, the β -migratory insertion of **12** and **13** are not likely relevant to the β -migratory insertion processes that occur in synthetically relevant transition metal-catalyzed carbocyclization protocols.^{2,47}

Conversion of 5 to 6. The zero-order dependence of the rate of conversion of 5 to 6 on nitrile concentration rules out a mechanism for the conversion of 5 to 6 initiated by attack of nitrile on 5 or a mechanism involving rapid and reversible conversion of 5 to III followed by rate-limiting ligand capture to form 6. Rather, our kinetic data are in accord with a mechanism involving rate-limiting, irreversible conversion of 5 to III followed by rapid, exothermic ligand capture to form **6** (Scheme 6). DFT calculations indicate that olefin β -migratory insertion of ethylene into the Pd-C bond of 9 to form the palladium β -agostic butyl complex [(H₂PCH=CHPH₂)Pd(CH₂- $CH_2CH_2CH_3)$ ⁺ is exothermic by ~8 kcal mol⁻¹ and, as noted above, complexation of ethylene to the β -agostic complex 8 is exothermic by ~ 12 kcal mol⁻¹. Because NCAr and ethylene possess comparable ligating ability with respect to cationic Pd(II) complexes, 16,24,36 we estimate that the conversion of 5 to 6 is also exothermic by ~ 20 kcal mol⁻¹.⁴⁸ From this value and from the enthalpy of activation for the conversion of 5 to 6 (ΔH^{\ddagger} = 13.5 kcal mol^{-1}), we estimate that the enthalpy of activation for the reverse reaction ($6 \rightarrow 5$) is $\Delta H^{\ddagger} \approx 33$ kcal mol⁻¹, which clearly renders conversion of 5 to 6 irreversible under reaction conditions. Consistent with this conclusion, β -alkyl elimination has been observed only in the case of electrophilic d⁰metallocene complexes⁴⁹ and in strained cyclobutylmethyl^{45,46} and cyclopropylmethyl complexes.50,51 Because conversion of **5** to **6** is irreversible, and because the stereochemistry of alkyl olefin chelate complex **5** is likely determined thermodynamically (see above), conversion of **5** to **6** represents the stereochemistry-determining step in the palladium-catalyzed cyclization/hydrosilylation of **1**.

Effect of the Chelate on Olefin β -Migratory Insertion. Activation parameters for olefin β -migratory insertion have been determined for a number of nonchelated, cationic palladium alkyl olefin complexes.^{15,16,25,26,30,31} Notable among these is the β -migratory insertion of the ethyl ethylene complex [(phen)- $Pd(Et)(H_2C=CH_2)]^+ [BAr_4]^- (14)$ to form the *n*-butyl complex $[(\text{phen})\text{Pd}(\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3)]^+$ [BAr₄]⁻ (**15**),¹⁵ as complexes **5**, 6, 14, and 15 all possess the identical (phen)Pd⁺ core. Activation parameters for conversion of 5 to 6 differ significantly from those for conversion of 14 to 15, pointing to the influence of the hexenyl chelate on the energetics of olefin β -migratory insertion. For example, the entropy of activation for the conversion of 5 to 6 ($\Delta S^{\ddagger} = -15 \pm 2 \text{ eu}$) is significantly more negative than is the entropy of activation for conversion of 14 to 15 ($\Delta S^{\ddagger} = -3.7 \pm 2$ eu); the latter value is typical for the olefin β -migratory insertion of nonchelated, late transition metal complexes.^{39,52,53} Because the olefin ligand of 5 is oriented perpendicular to the coordination plane in the ground state but must lie parallel to the coordination plane in the transition state for β -migratory insertion,⁵⁴ the negative entropy of activation for the conversion of 5 to 6 indicates that the hexenyl chain adopts a more conformationally rigid orientation when the olefin is oriented in the coordination plane as opposed to perpendicular to the coordination plane. Although the olefin of 14 must also undergo 90° rotation prior to olefin β -migratory insertion, rotation of the ethylene ligand of 14 requires no reorganization elsewhere in the molecule.

Despite the less favorable ΔS^{\dagger} for the conversion of 5 to 6 relative to ΔS^{\ddagger} for the conversion of 14 to 15, the free energy of activation for the conversion of **5** to **6** ($\Delta G^{\ddagger} = 16.9 \pm 0.1$ kcal mol^{-1}) is 2.6 kcal mol^{-1} lower than is the free energy of activation for the conversion of 14 to 15 ($\Delta G^{\dagger} = 19.5 \pm 0.5$ kcal mol⁻¹) due to the significantly lower enthalpy of activation for the conversion of 5 to 6 ($\Delta H^{\ddagger} = 13.5 \pm 0.6 \text{ kcal mol}^{-1}$) relative to the conversion of 14 to 15 ($\Delta H^{\ddagger} = 18.5 \pm 0.6$ kcal mol⁻¹).⁵⁵ This large difference in the enthalpy of activation $(\Delta \Delta H^{\ddagger} = 5 \text{ kcal mol}^{-1})$ represents the most conspicuous difference in the activation parameters for the olefin β -migratory insertion of 5 and 14. We attribute this large $\Delta \Delta H^{\ddagger}$ to groundstate destabilization of the alkyl olefin chelate complex 5.56 Assuming the preferred conformation of a transition metal alkyl olefin chelate complex mirrors that of a substituted cyclohexane ring, destabilization of 5 relative to 14 is suggested by the pseudoaxial orientation of the α -triethylsilylmethyl group of 5. Presumably, unfavorable steric interactions within the hexenyl chain of 5 that result from the pseudoaxial orientation of the

⁽⁴⁷⁾ Flood also noted that "incorporation of substantial ring strain and conformational restrictions of the Pt–CH₂ group in the transition state [for the β -migratory insertion of **13**], especially the former, make the transition state potentially quite atypical."^{46b}

⁽⁴⁸⁾ Although this analysis does not account for the likely destabilization of both 5 and 6 due to the presence of the hexenyl chelate and cyclopentyl ring, respectively, 5 and 6 are likely destabilized by a comparable amount relative to the corresponding acyclic derivatives. Destabilization of 5 by ~5 kcal mol⁻¹ relative to a nonchelated alkyl olefin complex is suggested by the lower ΔH[‡] for β-migratory insertion of 5 relative to that for unchelated derivative 14 (ΔΔH[‡] = 5 kcal mol⁻¹) and by the pseudoaxial orientation of the α-triethylsilyl group of 5 in solution. Similarly, because there is approximately 6.5 kcal mol⁻¹ of strain energy associated with formation of a cyclopentyl ring, cyclopentylmethyl complex 6 is likely destabilized by ~6 kcal mol⁻¹ relative to the corresponding acyclic alkyl complex.

⁽⁵³⁾ Although the entropy of activation for the reversible β -migratory insertion of the platinum 4-pentenyl chelate complex 13-1,1-d₂ was near zero ($\Delta S^{\dagger} = -0.5 \pm 1.6 \text{ eu}$), ¹H⁻¹H NOESY analysis of 13-1,1-d₂ was consistent with orientation of the olefin in or near the coordination plane, and for this reason, no significant olefin rotation or reorganization of the pentenyl chain was required for olefin β -migratory insertion.^{46b}

^{(54) (}a) Thorn, D. L.; Hoffmann, R. J. Am. Chem. Soc. 1978, 100, 2079. (b) Collman, J. P.; Hegedus, L. S.; Norton, J. R.; Finke, R. G. Principles and Applications of Organotransition Metal Chemistry; University Science Books: Mill Valley, CA, 1987.

α-triethylsilylmethyl group are less severe than is the steric interaction between the α-triethylsilylmethyl group and the phenanthroline ligand when the former adopts a pseudoequatorial orientation. Ground-state destabilization has been previously invoked to rationalize the decreasing ΔG^{\ddagger} for β-migratory insertion of propylene into the Pd–CH₃ bond of the palladium diimine complexes {[ArN=C(Me)C(Me)=NAr]Pd(Me)CH₂= CHMe}⁺ with the increasing steric bulk of the diimine ligand.³⁰

We considered two mechanisms by which the ground-state destabilization of 5 could decrease ΔH^{\ddagger} for the conversion of 5 to 6 relative to that of 14 to 15. The in-plane rotamer of cationic palladium(II) phenanthroline olefin complexes is ~ 10 kcal mol^{-1} less stable than is the perpendicular rotamer;¹⁴⁻¹⁶ calculations attribute destabilization of the in-plane rotamer to unfavorable steric interaction of the olefin ligand with the cis ligands.⁵⁷ Because it appears likely that the energy barrier for olefin rotation contributes significantly to the energy barrier for olefin β -migratory insertion,⁵⁴ destabilization of the perpendicular rotamer of 5 relative to the in-plane rotamer due to strain within the hexenyl chain would lead to lower ΔH^{\ddagger} for conversion of 5 to 6 relative to the conversion of 14 to 15. Alternatively, DFT calculations for the β -migratory insertion of ethylene into the Pd-CH₃ bond of [(HN=CHCH=NH)Pd- $(Me)(H_2C=CH_2)$ ⁺ (16) to form [(HN=CHCH=NH)Pd(CH₂- CH_2CH_3]⁺ (17) indicate that the CH_3 -Pd-ethylene_(centroid) angle decreases from 95° in the in-plane rotamer of 16 to 75° in the transition state for conversion of 16 to 17.58 Therefore, compression of the C–Pd–olefin(centroid) angle of 5 due to strain within the hexenyl chain could increase the extent of C-C bond formation in the transition state for the conversion of 5 to 6 relative to the transition state for the conversion of 14 to 15, leading to a lower ΔH^{\ddagger} for the conversion of 5 to 6 relative to the conversion of 14 to 15.

Formation of Carbonyl Chelate Complex 7. In the absence of silane, palladium cyclopentylmethyl complex 6 rearranges within 2 h at -9 °C to form the carbonyl chelate complex 7 with retention of stereochemistry (Scheme 2). Stereoselective conversion of 6 to 7 likely occurs via iterative β -hydride elimination/addition to form the palladium cyclopentyl intermediate **IX** without displacement of the olefin ligand from intermediates **VII** and **VIII**, followed by highly exoergonic complexation of the pendant carbonyl group to form 7 (Scheme 10). An analogous mechanism was proposed for formation of carbonyl chelate complex **7a** from stoichiometric reaction of **1** with **2c**.¹⁷ Because both the formation and silylation of **7** are much slower than is the silylation of **6** under catalytic conditions (see below), we can conclusively rule out formation of **7** in the palladium-catalyzed cyclization/hydrosilylation of **1**.

Silvlation of Palladium Alkyl Complexes. The first-order dependence of the rate of silvlation of 7 on silane concentration rules out a mechanism for the silvlation of 7 initiated by ratelimiting dissociation of the chelated carbonyl group. Furthermore, the much lower rate for the silvlation of 7, which possesses a tightly coordinated carbonyl chelate ligand, relative to the silvlation of 6, which possesses a labile NCAr ligand, argues against mechanisms for the silvlation of 7 involving Pd-C bond cleavage without prior silane coordination or Pd-C bond cleavage from a five-coordinate palladium silane complex. Rather, our data are in accord with a mechanism for the conversion of 7 to 3 involving associative displacement of the carbonyl ligand of 7 with silane to form the four-coordinate palladium silane intermediate X followed by Pd-C bond cleavage to form 3, perhaps via σ -bond metathesis (Scheme 10).59

⁽⁵⁵⁾ The free energy of activation for the β -migratory insertion of propene into the Pd–CH₃ bond of the cationic palladium propylene complex [(N–N)-Pd(Me)CH₂=CHMe]⁺ [N–N = ArN=C(Me)C(Me)=NAr, Ar = 2,6-C₆H₃i-Pr₂] was only 0.5 kcal mol⁻¹ higher than was ΔG^{+} for the insertion of ethylene into the Pd–CH₃ bond of the corresponding palladium ethylene complex [(N–N)Pd(Me)CH₂=CH₁]^{+,2} For this reason, it appears unlikely that the lower ΔG^{+} and ΔH^{+} for olefin β -migratory insertion for 5 relative to that for 14 is due to the insertion of an α -olefin in the case of 5 and ethylene into the Pd–CH₃ bond of [(phen)Pd(CH₃)(H₂C=CH₂)]⁺ [BAr₄]⁻ was ~1 kcal mol⁻¹ lower than was β -migratory insertion of ethylene into the Pd–CH₃CH₃ bond of 14.^{15,16} This comparison suggests that ΔG^{+} for olefin β -migratory insertion increases with increasing substitution of the palladium σ -bound carbon atom. For this reason, it appears highly unlikely that the lower ΔG^{\pm} for the conversion of 5 to 6 relative to the conversion of 14 to 15 is due to migration of a Pd-secondary alkyl group in the case of 5 and a palladium-primary alkyl group in the case of 14.

⁽⁵⁶⁾ Enthalpic destabilization of 5 relative to 14 is not inconsistent with the failure to generate detectable amounts of the nonchelated palladium hexenyl complex 5-L from reaction of 5 with 1 or NCAr (Scheme 3). An entropy of reaction for the conversion of 5 to 5-L of ΔS ≈ -30 eu can be estimated from the values determined for displacement of the six-membered carbonyl chelate from the cationic palladium complex [(phen)Pd[CH₂-CH₂COOMe]⁺ [BAr₄]⁻ with ethylene and similar ligands (ΔS = -27)

CH₂CH₂COOMe]⁺ [BAr₄]⁻ with ethylene and similar ligands ($\Delta S = -27$ to -34 eu).¹⁶ Because NCAr and an α -olefin are of comparable ligating ability with respect to Pd(II),³⁶ the enthalpy for the conversion of **5** to **5-L** would be $\Delta H \approx 0$ if there were no significant destabilization of **5**. However, if we attribute the 5 kcal mol⁻¹ decrease in ΔH^{+} for β -migratory insertion of **5** relative to that for 14 solely to ground-state destabilization of **5**, the enthalpy of reaction for the conversion of **5** to **5-L** would be $\Delta H \approx -5$ kcal mol⁻¹. From these values ($\Delta H \approx -5$ kcal mol⁻¹, $\Delta S \approx -30$ eu) we estimate a free energy of reaction for the conversion of **5** to **5-L** of $\Delta G \approx 2$ kcal mol⁻¹, which corresponds to an equilibrium constant of $K_{eq} \approx 8 \times 10^{-3}$ at -62 °C. Therefore, **5-L** should constitute less than 0.1% of a mixture of **5** (42 mM), **1** (42 mM), and NCAr (42 mM) at -62 °C and, therefore, **5-L** have the undetectable by ¹H NMR analysis under these conditions. (57) Hay, P. J. J. Am. Chem. Soc. **1981**, 103, 1390.

⁽⁵⁸⁾ Svensson, M.; Matsubara, T.; Morokuma, K. Organometallics 1996, 15, 5568.

⁽⁵⁹⁾ Alternatively, Pd-C bond cleavage could occur via an oxidative addition/ reductive elimination sequence.

Scheme 11

All available evidence regarding the silvlation of 6 points to an associative mechanism involving palladium silane intermediate IV (Scheme 6). The strong inhibition of the rate of the silvlation of 6 by CD₃CN and the much higher rate of the silvlation of 6 relative to the silvlation of 7 argues against mechanisms for the silvlation of 6 involving Pd-C bond cleavage without prior silane coordination or Pd-C bond cleavage from a five-coordinate palladium silane complex. Although the first-order dependence of the rate of the silvlation of 6 on silane concentration was not directly established, silane competition experiments support this contention. Provided that scrambling of the silyl group of 4b' with free silane is slow relative to irreversible conversion of 4b' to 5',^{60,61} the ratio of silvlated carbocycles formed in the catalytic cyclization/hydrosilylation of 1 with an excess 1:1 mixture of two different silanes corresponds to the relative rate at which the two silanes react with palladium cyclopentylmethyl complex 6'. Therefore, silane competition experiments establish that the rate of silylation of 6' increases with both the decreasing steric bulk and increasing electron density of the silane. Both of these observations are consistent with a mechanism for silvlation involving direct attack of the silane on the palladium atom of 6'.⁶²

Kinetics of Catalytic Cyclization/Hydrosilylation. The kinetics of the catalytic cyclization/hydrosilylation of **1** and HSiEt₃ were interpreted in the context of the simplified mechanism depicted in Scheme 11, which was constructed on the basis of the following assumptions: (1) conversion of **4b** to **5**, **5** to **6**, and **6** to **4b** is irreversible, (2) the total palladium concentration equals the initial concentration of **2b** ([Pd]_{tot} = [**2b**]₀), (3) conversion of **2b** to **4b** is fast relative to catalyst turnover,⁶³ and (4) the rate of silylation of **6** depends linearly on silane concentration (see above). Steady-state treatment of intermediates **4b** and **6** produced the three-term rate law depicted in eq 1, which simplifies to the two-term rate law depicted in

 $k_1[1] \gg k_2$ and $k_3[HSiEt_3] \gg k_2$: rate = $k_2[Pd]_{tot}$ eq 3

eq 2 when the conversion of 4 to 5 is much faster than is the conversion of 5 to 6, and to the single-term rate law depicted in eq 3, when both the conversion of 4 to 5 and the silylation of 6 are fast relative to the conversion of 5 to $6^{.64}$

All of our experimental observations point to turnover-limiting conversion of alkyl olefin chelate complex 5 to cyclopentylmethyl complex 6 in the catalytic conversion of 1 to 3 at high silane concentration ([HSiEt₃] $_0 = 0.16$ M). For example, the empirical rate law for the catalytic cyclization/hydrosilylation of **1** and HSiEt₃ at high silane concentration (rate = $k_{sat}[2b]_{0}$) is of the same form as the derived rate law depicted in eq 3 (rate = k_2 [Pd]_{tot}). Likewise, the activation parameters for the catalytic conversion of 1 to 3 at high silane concentration $(\Delta G^{\dagger}_{232\mathrm{K}} = 16.8 \pm 0.1 \text{ kcal mol}^{-1}; \Delta H^{\ddagger} = 13 \pm 1 \text{ kcal mol}^{-1};$ $\Delta S^{\ddagger} = -15 \pm 3$ eu) do not differ significantly from those determined independently for the conversion of 5 to 6 (ΔG^{\dagger}_{232} $\kappa = 16.9 \pm 0.1 \text{ kcal mol}^{-1}; \Delta H^{\ddagger} = 13.5 \pm 0.6 \text{ kcal mol}^{-1}; \Delta S^{\ddagger}$ $= -15 \pm 2$ eu). Furthermore, alkyl olefin chelate complex 5 was the only palladium species detected during catalytic cyclization/hydrosilylation of 1 at high silane concentration, which establishes 5 as the catalyst resting state under these conditions.

The pronounced positive curvature of the concentration versus time plots for the catalytic cyclization/hydrosilylation of **1** at lower silane concentration ([HSiEt₃]₀ = 90 mM, Figure 6) indicates that under these conditions, the rate of silylation of cyclopentylmethyl complex **6** is both comparable to the rate of conversion of **5** to **6** and is dependent on silane concentration. Iterative fitting of two sets of concentration versus time data for the catalytic cyclization/hydrosilylation of **1** at low silane concentration ([HSiEt₃]₀ = 90 mM) to the rate law depicted in eq 2 provided a best fit with $k_2 = 7.6 \pm 0.2 \times 10^{-4} \text{ s}^{-1}$ and k_3 = 0.12 ± 0.03 M⁻¹ s⁻¹. Noteworthy is that the value for k_2 extracted from this analysis is in good agreement with the value obtained under saturation conditions ($k_{\text{sat}} = k_2 = 7.74 \pm 0.06 \times 10^{-4} \text{ s}^{-1}$). Furthermore, because silylation of **6** is likely

⁽⁶⁰⁾ The designators 4b', 5', and 6' refer to the palladium silyl, alkyl olefin chelate, and cyclopentylmethyl derivatives, respectively, with an undefined silyl group -SiMe₂R (R = Et, *n*-octyl, OSiMe₃, Ph, 4-C₆H₄NMe₂, 4-C₆H₄-OMe, 4-C₆H₄F, or 4-C₆H₄CF₃) generated in the catalytic silane competition experiments.

⁽⁶¹⁾ Brookhart has shown that reaction of palladium silyl olefin complex [(phen)-Pd(SiEt₃)(CH₂=CH*t*-Bu)]⁺ [BAr₄]⁻ [Ar = 3,5-C₆H₃(CF₃)₂] (**4e**) with HSiPh₃ formed (3,3-dimethylbutyl)triethylsilane to the exclusion of (3,3-dimethylbutyl)triphenylsilane,¹⁴ which indicates that olefin insertion/silylation of **4e** is much faster than is silyl exchange. Because NCAr and an olefin of **1** are of comparable ligating ability with respect to cationic Pd(II) complexes,³⁶ this result strongly suggests that **4b** does not undergo silyl exchange prior to conversion to **5**.

⁽⁶²⁾ Silane competition experiments are in accord with either rate-limiting conversion of 6 to IV followed by rapid conversion of IV to 3, or rapid and reversible conversion of 6 to IV followed by rate-limiting conversion of IV to 3. The transition states for both the conversion of 6 to IV (6[‡]) and VI to 4b (IV[±]) should possess a greater degree of covalent Pd-Si bond character than do 6 and IV, respectively. Likewise, the Pd-Si bond distance should decrease upon conversion of both 6 to 6[±] and IV to IV[±]. Therefore, both 6[±] and IV[±] should be destabilized by the decreasing electron density and increasing steric bulk of the silane.

⁽⁶³⁾ Available evidence supports each of these assumptions. The failure of 1-2,6d₂ to exchange with the 5-hexenyl group of **5** establishes irreversible conversion of **4b** to **5**, analysis of DFT data supports the irreversible conversion of a Pd–C bond with a hydrosilane.¹⁴ Visual inspection of catalytically active mixtures of **1**, **2b**, and HSiEt₃ revealed no darkening of the solution prior to complete consumption of **1**, which argues against catalyst decomposition during cyclization/hydrosilylation. The much faster conversion of **2b** and HSiEt₃ to **4b** (5 min at -80 °C) relative to the conversion of **5** to **6** ($t_{1/2} = 22$ min at -41 °C) ensures rapid activation of precatalyst **2b** relative to catalyst turnover.

⁽⁶⁴⁾ Although the mechanism for cyclization/hydrosilylation depicted in Scheme 6 likely involves nitrile inhibition of both the conversion of **4b** to **5** and the conversion of **6** to **4b**, both these transformations are fast relative to the conversion of **5** to **6** at high silane concentration ([HSiEt₃]₀ = 0.16M). Although conversion of **6** to **4b** becomes kinetically relevant at low silane concentration, nitrile concentration was invariant ([NCAr] = 42 mM) throughout complete conversion of **1** to **3** and between multiple experiments. Therefore, k_3 corresponds to a macroscopic rate constant for the conversion of **6** to **4b** for the specific case where [NCAr] = 42 mM.

Figure 9. Theoretical plot of k_{obs} versus [HSiEt₃] for the catalytic cyclization/hydrosilylation of 1 and HSiEt₃ calculated from eq 2 where [1] = 85 mM, [Pd]_{tot} = 12 mM, and [NCAr] = 42 mM, $k_2 = 7.6 \times 10^{-4} \text{ s}^{-1}$, and $k_3 = 0.12 \text{ M}^{-1} \text{ s}^{-1}$.

inhibited by nitrile, the value for k_3 extracted from this analysis ([NCAr] = 42 mM) is in accord with the rate constant estimated for the silulation of **6** under stoichiometric conditions ([NCAr] $\approx 0 \text{ mM}, k \ge 0.19 \text{ M}^{-1} \text{ s}^{-1}$).²⁷

To better visualize the dependence of the rate of catalytic cyclization/hydrosilylation on silane concentration, a hypothetical plot of k_{obs} versus [HSiEt₃] for the catalytic cyclization/ hydrosilylation of 1 and HSiEt₃ was generated by solving eq 2 for k_{obs} ($k_{obs} = rate/[1]$) as a function of [HSiEt₃] in 0.01 M increments from 0 to 0.50 M, where [1] = 85 mM, $[Pd]_{tot} =$ 12 mM, and [NCAr] = 42 mM, $k_2 = 7.6 \times 10^{-4} \text{ s}^{-1}$, and $k_3 =$ $0.12 \text{ M}^{-1} \text{ s}^{-1}$ (Figure 9). This theoretical plot indicates that the rate of catalytic cyclization/hydrosilylation should decrease less than 3% as the silane concentration decreases from 0.16 to 0.080 M, which is in accord with the observed linearity of the concentration versus time plots for catalytic cyclization/hydrosilylation at high silane concentration ($[HSiEt_3]_0 = 0.16 \text{ M}$) through 90% conversion (Figure 6). Likewise, the theoretical plot predicts that the rate of catalytic cyclization/hydrosilylation should decrease \sim 50% as the silane concentration decreases from 90 to 5 mM, which is in accord with the pronounced positive curvature of the concentration versus time plots for catalytic cyclization/hydrosilylation at low silane concentration ([HSiEt₃]₀ = 90 mM) through 95% conversion (Figure 6).

Conclusions

All of our observations support the mechanism for the cyclization/hydrosilylation of **1** and HSiEt₃ catalyzed by **2b** depicted in Scheme 6. Rapid and reversible complexation of one of the double bonds of **1** with palladium silyl intermediate **4b** would form the unobserved palladium olefin complex **I**. β -Migratory insertion of the olefin into the Pd–Si bond of **I** to form the palladium 5-hexenyl complex **II**, followed by rapid, irreversible complexation of the pendant olefin would form alkyl olefin chelate complex **5**. Although not detected, associative displacement of the chelated olefin of **5** by exogenous ligand is likely and, for this reason, the diastereoselective formation of **5** is under thermodynamic control. β -Migratory insertion of the palladium cyclopentylmethyl complex **III** followed by rapid,

Figure 10. Atom-labeling schemes for phenanthroline, NCAr, BAr_4^- , 6, and 7.

exothermic ligand capture with NCAr forms 6. Conversion of 5 to 6 is likely irreversible and is therefore the stereochemistrydetermining step in catalytic cyclization/hydrosilylation. The enthalpy of activation for β -migratory insertion of the olefin into the Pd–C bond of **5** is 5 kcal mol⁻¹ lower than is ΔH^{\ddagger} for β -migratory insertion of the olefin into the Pd-C bond of the analogous nonchelated alkyl olefin complex 14. We attribute this large $\Delta \Delta H^{\ddagger}$ to ground-state destabilization of **5** relative to 14. Associative silvlation of 6 via palladium-silane intermediate IV releases carbocycle 3 and regenerates palladium silyl complex 4b. Under catalytic conditions, the second-order rate constant for the silvlation of 6 ($k_3 = 0.12 \pm 0.03 \text{ M}^{-1} \text{ s}^{-1}$) is ~ 160 times greater than is the first-order rate constant for conversion of **5** to **6** ($k_2 = 7.6 \pm 0.2 \times 10^{-4} \text{ s}^{-1}$), and both of these processes are slow relative to the conversion of 4b to 5. Therefore, at high silane concentration ($[HSiEt_3] > 85 \text{ mM}$), silvlation of 6 is fast relative to conversion of 5 to 6, and the latter step alone determines the rate of catalytic cyclization/ hydrosilylation. Conversely, at low silane concentration ([HSi- Et_3] < 85 mM), the rate of silvlation of **6** becomes competitive with the rate of conversion of 5 to 6 and the rate of catalytic cyclization/hydrosilylation depends on silane concentration. Although cyclopentylmethyl complex 6 rearranges to oxo chelate complex 7 in the absence of silane, neither the conversion of 6 to 7 nor the silvlation of 7 with HSiEt₃ to form 3 is fast enough to compete with the silvlation of 6 under catalytic conditions.

Experimental Section

General Methods. Low-temperature NMR spectra were recorded at 500 MHz for ¹H and 125 MHz for ¹³C, except where noted; roomtemperature NMR spectra were recorded at 400 MHz for ¹H and 100 MHz for ¹³C, except where noted. NMR Probe temperatures were measured with a methanol thermometer and were maintained to within \pm 0.5 °C. Atom-labeling schemes for phenanthroline, NCAr, BAr₄⁻, 6, and 7 are shown in Figure 10. ¹H NMR yields for the conversion of 4b to 5, 5 to 6, and 6 to 7 were determined employing a 10 s delay between pulses. Unless noted otherwise, error limits for rate constants refer to the standard deviation of the slope of the respective kinetic plot or to the standard deviation of the average of multiple experiments. The volumes of low-temperature NMR solutions were calculated from the room-temperature volume and the temperature dependence of the density of CH₂Cl₂; volumes given refer to the volume at the specified reaction temperature. Elemental analysis was performed by Complete Analysis Laboratories, Inc. (Parsippany, NJ).

[(phen)Pd(SiEt₃)(NCAr)]⁺ [BAr₄]⁻ (4b). HSiEt₃ (2.62 mg, 22.5 μ mol) was added via syringe to an NMR tube containing a solution of [(phen)Pd(Me)(NCAr)]⁺ [BAr₄]⁻ (2b) (31.6 mg, 22.5 µmol) in CD₂- Cl_2 (0.54 mL) at -78 °C. The tube was shaken briefly and placed into the probe of an NMR spectrometer pre-cooled at -81 °C. Reaction progress was determined by measuring the disappearance of the Pd-CH₃ resonance of **2b** (δ 1.26) relative to the para phenyl protons of the $[BAr_4]^-$ counterion (δ 7.46) in the ¹H NMR spectrum. After 5 min, 2b was completely consumed to form 4b in $101 \pm 10\%$ yield. Complex 4b was thermally sensitive and characterized in solution at -81 °C by ¹H NMR spectroscopy. ¹H NMR (CD₂Cl₂, -81 °C): δ 9.02 (d, J = 4.9 Hz, 1 H, H_{phen}), 8.83 (d, J = 4.5 Hz, 1 H, H_{phen}), 8.55 (d, J = 8.2Hz, 1 H, H_{phen}), 8.43 (d, J = 8.3 Hz, 1 H, H_{phen}), 8.39 (s, 2 H, H_{o}), 8.36 (s, 1 H, H_p), 7.93 (m, 3 H, H_{phen}), 7.78 (dd, J = 4.8, 8.0 Hz, 1 H, $H_{\rm b}$), 7.73 (s, 8 H, $H_{\rm o'}$), 7.46 (s, 4 H, $H_{\rm p'}$), 1.06 (t, J = 7.5 Hz, 9 H, $SiCH_2CH_3$), 0.97 (q, J = 7.5 Hz, 6 H, $SiCH_2CH_3$).

{(phen)Pd[η^1 , η^2 -CH(CH₂SiEt₃)CH₂C(CO₂Me)₂CH₂CH= CH₂]⁺ [BAr₄]⁻ (5). Dimethyl diallylmalonate (1) (4.7 μ L, 0.023 mmol) was added via syringe to an NMR tube containing a solution of [(phen)-Pd(SiEt₃)(NCAr)]⁺ [BAr₄]⁻ (**4b**) (0.023 mmol) in CD₂Cl₂ (0.55 mL) at -78° C. The tube was shaken briefly and placed in the probe of an NMR spectrometer pre-cooled at -81 °C. The probe was warmed at -62 °C and the solution was analyzed periodically by ¹H NMR spectroscopy. Reaction progress was determined by integrating the carbomethoxy resonances of 5 (δ 3.68 and 3.43) relative to that of the para phenyl proton of the BAr_4^- counterion (δ 7.49). After 20 min, **4b** was completely consumed to form 5 as the exclusive product in 84% \pm 10% yield as a single diastereomer characterized by ¹H NMR spectroscopy. Complex 5 was thermally sensitive and was characterized in solution by ¹H NMR spectroscopy at -62 °C. Assignment of the proton resonances and $J_{\rm HH}$ coupling constants of 5 was aided by ¹H-¹H COSY analysis and by ¹H NMR analysis of the deuterated isotopomers {(phen)Pd[η^1 , η^2 -CD(CH₂SiEt₃)CH₂C(CO₂Me)₂CH₂CD= CH_2]⁺ [BAr₄]⁻ (**5**-d₂) and {(phen)Pd[η^1, η^2 -CH(CH₂SiEt₃)CD₂C(CO₂- $Me_2CD_2CH=CH_2$]⁺ [BAr₄]⁻ (5-d₄) (see Supporting Information).

For 5: ¹H NMR (CD₂Cl₂, -62 °C): δ 8.71 (d, J = 4.4 Hz, 1 H, H_a), 8.61 (d, J = 8.1 Hz, 1 H, H_c), 8.48 (dd, J = 1.2, 8.2 Hz, 1 H, H_c), 8.35 (dd, J = 1.2, 4.9 Hz, 1 H, H_a), 8.16 (s, 2 H, H_o), 8.14 (s, 1 H, H_p), 8.05 (dd, J = 5.2, 8.0 Hz, 1 H, H_b), 7.96 (s, 2 H, H_o), 7.87 (dd, J = 4.9, 8.1 Hz, 1 H, H_b), 7.74 (s, 8 H, $H_{o'}$), 7.49 (s, 4 H, H_p), 6.41 (dddd, J = 4.3, 8.2, 9.0, 16.1 Hz, 1 H, $-CH=CH_2$), 5.44 (d, J = 9.0 Hz, 1 H, $-CH=CH_2$), 3.43 (s, 3 H, CO₂Me), 3.02 (dd, J = 8.2, 12.7 Hz, 1 H, $-CH_2$ CH=CH₂), 2.66 (m, 1 H, Pd-CH), 2.22 (dd, J = 4.0, 12.6 Hz, 1 H, $-CH_2CH=CH_2$), 1.74, 1.70 [ABX, $J_{AB} = 15.6$ Hz, $J_{AX} = 10.9$ Hz, $J_{BX} = 5.4$ Hz, 2 H, Pd-CH(CH₂SiEt₃)CH₂], 1.23 [dd, J = 2.6, 13.3 Hz, 1 H, Pd-CH(CH₂SiEt₃)CH₂], 1.11 [t, J = 13.3 Hz, 1 H, Pd-CH(CH₂SiEt₃)], 0.94 (t, J = 7.9 Hz, 9 H, SiCH₂CH₃), 0.64 (q, J = 7.9 Hz, 6 H, SiCH₂CH₃).

{(**phen**)**Pd**[η^1 , η^2 -**CH**(**CH**₂**SiE**t₃)**CH**₂¹³**C**(¹³**CO**₂**E**t)₂**CH**₂**CH**= **CH**₂]}⁺ [**BAr**₄]⁻ (**5a**⁻¹³**C**₃). Reaction of diethyl diallylmalonate ¹³**C** labeled at each of the quaternary carbon atoms (**1a**⁻¹³**C**₃, 4.7 μ L, 0.023 mmol) and **4b** (0.023 mmol) in CD₂Cl₂ (0.56 mL) at -62° C, employing a procedure analogous to that used in the synthesis of **5**, gave **5a**⁻¹³**C**₃ as the exclusive product by ¹H NMR analysis. ¹³C{¹H} NMR (CD₂-Cl₂, -62 °C, labeled carbon atoms only): δ 172.6 (dd, J = 2.3, 55.3 Hz), 172.5 (d, J = 58.4 Hz), 65.5 (dd, J = 55.2, 58.4 Hz).

{(**phen**)**Pd**[η^{1} , η^{2} -¹³**CH**(¹³**CH**₂**SiEt**₃)¹³**CH**₂**C**(**CO**₂**Me**)₂¹³**CH**₂¹³**CH**= ¹³**CH**₂]}⁺ [**BAr**₄]⁻ (**5**-¹³**C**₆). Reaction of 1-1,2,3,5,6,7-¹³**C**₆ (4.2 μ L, 0.021 mmol) and **4b** (0.022 mmol) in CD₂Cl₂ (0.56 mL) at -60 °C employing a procedure analogous to that used to synthesize **5** gave **5**-¹³**C**₆ as the exclusive product by ¹H NMR analysis. ¹³C{¹H} NMR (CD₂Cl₂, 75 MHz -60 °C, labeled carbon atoms only): δ 103.7 (dd, J = 41, 47 Hz, -*C*H=CH₂), 87.5 (d, J = 47 Hz, -*C*H=*C*H₂), 50.0 [dd, J = 30, 36 Hz, Pd-*C*H(CH₂SiEt₃)CH₂], 39.2 [d, J = 36 Hz, Pd-CH(CH₂SiEt₃)- CH_2], 32.5 (d, J = 41 Hz, $-CH_2CH=CH_2$), 20.3 [d, J = 30 Hz, Pd-CH(CH_2SiEt_3)CH₂].

Exchange of 1-2,6- d_2 with 5. Diene 1-2,6- d_2 (5.88 μ L, 29.2 mmol) was added via syringe to an NMR tube containing a solution of 5 (~25 mmol) in CD₂Cl₂ (0.58 mL) at -80 °C. The tube was shaken briefly and placed in the probe of an NMR spectrometer cooled at -80 °C. The sample was maintained at -80 °C for 1.5 h and then warmed at -60 °C for 30 min. At this time, ¹H NMR analysis revealed approximately 5% conversion to 6 without formation of either free 1 or 5- d_2 .

trans-{(**phen**)**Pd**[**CH**₂**CHCH**₂**C**(**CO**₂**Me**)₂**CH**₂**CHCH**₂**SiEt**₃]-(**NCAr**)}⁺ [**BAr**₄]⁻ (6). An NMR tube containing a solution **5** (39 mM) and NCAr (39 mM) in CD₂Cl₂ was warmed at -41 °C and monitored periodically by ¹H NMR spectroscopy; reaction progress was determined by integrating the carbomethoxy resonances of **6** (δ 3.67 and 3.59) and **5** (δ 3.69 and 3.43) relative to the para phenyl resonances of the BAr₄⁻ counterion (δ 7.51). After 2 h, **5** had been completely consumed to form **6** in 96 ± 10% yield by ¹H NMR analysis. Complex **6** was thermally sensitive and was characterized in solution by ¹H and ¹³C NMR spectroscopy at ≤-41 °C. Assignment of proton resonances and *J*_{HH} coupling constants was aided by ¹H COSY analysis and by ¹H

NMR analysis of the labeled derivatives trans-{(phen)Pd[CH2CDCH2C-

For 6: ¹H NMR (CD₂Cl₂, -41 °C): δ 8.86 (dd, J = 1.0, 5.4 Hz, 1 H, H_a), 8.84 (dd, J = 1.5, 4.9 Hz, 1 H, H_a), 8.65 (s, 2 H, H_o), 8.64 (dd, J = 1.1, 8.6 Hz, 1 H, H_c), 8.55 (dd, J = 1.5, 8.4 Hz, 1 H, H_c), 8.38 (s, 1 H, H_p), 8.02 (d, J = 2.7 Hz, 2 H, H_d), 7.99 (dd, J = 5.4, 8.2 Hz, 1 H, $H_{\rm b}$), 7.86 (dd, J = 4.8, 8.2 Hz, 1 H, $H_{\rm b}$), 7.72 (s, 8 H, $H_{\rm o'}$), 7.51 (s, 4 H, H_p), 3.67 (s, 3 H, CO₂CH₃), 3.59 (s, 3 H, CO₂CH₃), 2.93 (dd, J = 7.4, 13.5 Hz, 1 H, H_3), 2.62 (dd, J = 6.3, 13.1 Hz, 1 H, H_5), 2.52 $(dd, J = 4.0, 7.7 Hz, 1 H, H_1), 2.18 (dd, J = 10.4, 13.4 Hz, 1 H, H_3),$ 2.09 (dd, J = 8.3, 10.8 Hz, 1 H, H_1), 1.80 (m, 1 H, H_2), 1.77 (dd, J =11.9, 12.9 Hz, 1 H, H_5), 1.67 (m, 1 H, H_6), 1.26 (dd, J = 3.0, 13.4 Hz, 1 H, H_7), 0.92 (t, J = 7.9 Hz, 9 H, $-\text{SiCH}_2\text{C}H_3$), 0.55 (q, J = 7.9 Hz, 6 H, $-\text{SiC}H_2\text{CH}_3$), 0.46 (dd, J = 11.9, 13.6 Hz, 1 H, H_7). ¹³C{¹H} NMR (CD₂Cl₂, -62 °C): δ 175.4 (CO₂CH₃), 175.2 (CO₂CH₃), 163.8 (q, $J_{\rm C}11_{\rm B} = 49.7$ Hz, superimposed on a septet, $J_{\rm C}^{10}{}_{\rm B} = 16.8$ Hz, $C_{\rm i}$), 159.4, 150.5, 149.6, 145.4, 142.4, 141.4 (Cphen), 136.6 (Co'), 136.1 (Co), 134.9 (q, ${}^{2}J_{CF} = 35.1$ Hz, C_{m}), 132.6, 132.0 (C_{phen}), 131.3 (C_{p}), 130.6 $(q, {}^{2}J_{CF} = 31.4 \text{ Hz}, C_{m'}), 129.9, 129.6, 127.9, 127.8 (C_{phen}), 126.4 (q,$ ${}^{1}J_{CF} = 273 \text{ Hz}, C_{r'}$, 124.1 (q, ${}^{1}J_{CF} = 274 \text{ Hz}, C_{r}$), 121.5, 113.8 (C_{i} and C_q , 119.5 ($C_{p'}$), 59.2 (C_4), 55.3 (CO_2CH_3), 55.2 (CO_2CH_3), 53.6 (C_2), 45.2, 44.8, 43.9 (*C*₃, *C*₅, and *C*₆) 32.4 (*C*₁), 16.0 (*C*₇), 9.5 (SiCH₂CH₃), 5.2 (SiCH₂CH₃).

trans-{(**phen**)**Pd**[**CH**₂**CHCH**₂¹³**C**(¹³**CO**₂**Et**)₂**CHCH**₂**SiEt**₃]-(**NCAr**)⁺ [**BAr**₄]⁻ (**6a**-¹³**C**₃). Warming a solution of **5a**-¹³**C**₃ (4.66 μ L, 0.023 mmol) in CD₂Cl₂ (0.60 mL) at -41 °C for 2 h formed **6a**-¹³C₃ as the exclusive product by ¹H NMR analysis. ¹³C{¹H} NMR (CD₂-Cl₂, -41 °C, labeled carbon atoms only): δ 175.4 (dd, J = 1.4, 58.4 Hz, CO₂CH₃), 175.2 (dd, J = 1.4, 58.4 Hz, CO₂CH₃), 59.2 (t, J = 58.4 Hz, C_4).

trans-{(**phen**)**Pd**[¹³**CH**₂¹³**CH**¹³**CH**₂**C**(**CO**₂**Me**)₂¹³**CH**₂¹³**CH**₁³**CH**₂**SiEt**₃]-(**NCAr**)⁺ [**BAr**₄]⁻ (**6**⁻¹³**C**₆). Warming a solution of **5**⁻¹³**C**₆ (0.021 mmol) in CD₂Cl₂ (0.60 mL) at -40 °C for 2 h formed **6**⁻¹³**C**₆ as the exclusive product by ¹H NMR analysis. ¹³C{¹H} NMR (CD₂Cl₂, 75 MHz -40 °C, labeled carbon atoms only): δ [51.8 (q), 43.3 (q), *C*₂ and *C*₆]], [42.7 (d), 42.2 (d), 31.0 (d), *C*₁, *C*₃ and *C*₅], 14.8 (d, *C*₇); all ¹*J*_{CC} = 31-34 Hz.

Kinetics of the Conversion of 5 to 6. An NMR tube containing an equimolar solution of 5 and NCAr (42 mM) in CD_2Cl_2 was warmed at -41 °C and monitored periodically by ¹H NMR spectroscopy. The

concentration of **5** was determined by integrating the carbomethoxy resonances of **5** (δ 3.69 and 3.43) versus the para phenyl proton of the BAr₄⁻ counterion (δ 7.49). A plot of ln[**5**] vs time was linear to >3 half-lives with a first-order rate constant of $k = 5.04 \pm 0.05 \times 10^{-4}$ s⁻¹; two identical experiments gave an average value of $k = 5.2 \pm 0.8 \times 10^{-4}$ s⁻¹. The first-order rate constant for the conversion of **5** to **6** was determined at -62, -55, -51, and -30 °C (Table 1). A plot of ln *k*/T versus 1/*T* provided the activation parameters for the conversion of **5** to **6**; $\Delta H^{\ddagger} = 13.5 \pm 0.6$ kcal mol⁻¹, and $\Delta S^{\ddagger} = -15 \pm 2$ eu (Figure 3).

trans,trans-{(phen)Pd[CHCH(Me)CH(CH2SiEt3)CH2C(COOMe)-

(COOMe)]}⁺ (BAr₄]⁻ (7). Triethylsilane (12.3 μ L, 0.077 mmol) was added via syringe to a solution of [(phen)Pd(Me)(NCCH₃)]⁺ [BAr₄]⁻ (2c) (93 mg, 0.077 mmol) in CH₂Cl₂ (25 mL) at -78 °C, stirred for 30 min, and treated with 1 (16 μ L, 0.077 mmol). The resulting solution was warmed to room temperature, stirred for 2 h, and concentrated under vacuum to form a yellow glass that was triturated with hexanes (3 × 5 mL) and dried under vacuum to give 7 (52 mg, 49%) as a yellow powder. ¹H NMR resonances were assigned on the basis of ¹H-⁻¹H COSY analysis; the relative stereochemistry of 7 was assigned via degradation with DSiEt₃.

For 7: ¹H NMR (CDCl₃, 23 °C): δ 8.92 (dd, J = 1.4, 4.9 Hz, 1 H, H_c), 8.85 (dd, J = 1.4, 5.4 Hz, 1 H, H_c), 8.64 (dd, J = 1.2, 8.2 Hz, 1 H, H_a), 8.62 (dd, J = 1.6, 8.4 Hz, 1 H, H_a), 8.07, 8.03 (ABq, J = 8.9Hz, 2 H, H_d), 7.95 (dd, J = 4.8, 8.3 Hz, 1 H, H_b), 7.89 (dd, J = 5.3, 8.2 Hz, 1 H, H_b), 7.72 (t, J = 2.4 Hz, 8 H, $H_{o'}$), 7.55 (s, 4 H, $H_{p'}$), 4.16 (s, 3 H, H_{13}), 3.78 (s, 3 H, H_{11}), 2.85 (dd, J = 7.1, 13.0 Hz, 1 H, H_4), 2.47 (d, J = 10.5 Hz, 1 H, H_1), 1.70 (m, 1 H, H_3), 1.67 (d, J = 12.8Hz, 1 H, H_4), 1.47 (m, 1 H, H_2), 1.20 (d, J = 6.5 Hz, 3 H, H_6), 1.06 $(dd, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 H, H_9), 0.58 (q, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 H, H_9), 0.58 (q, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 H, H_9), 0.58 (q, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 H, H_9), 0.58 (q, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 H, H_9), 0.58 (q, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 H, H_9), 0.58 (q, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 Hz, 9 H, H_9), 0.58 (q, J = 2.4, 14.4 Hz, 1 H, H_7), 0.97 (t, J = 7.9 Hz, 9 Hz,$ J = 7.8 Hz, 6 H, H_8), 0.37 (dd, J = 11.2, 14.4 Hz, 1 H, H_7). ¹³C{¹H} NMR (CDCl₃, 23 °C): δ 191.5 (C₁₂), 171.7 (C₁₀), 161.9 (q, J_{CB} = 50.0 Hz, Ci'), 151.7, 149.1 (Ca), 147.8, 143.8 (Ce), 139.7, 139.1 (Cb), 134.9 ($C_{o'}$), 130.9, 130.2 (C_{f}), 129.2 (q, ${}^{2}J_{CF} = 31.7$ Hz, $C_{m'}$), 128.0, 127.5, 126.0, 125.4 ($C_{\rm b}$ and $C_{\rm c}$), 124.6 (q, ${}^{1}J_{\rm CF} = 272.8$ Hz, $C_{\rm r'}$), 117.6 $(C_{p'})$, 68.5, 56.5, 53.8, 53.2, 42.1, (C_1, C_2, C_5, C_{11}) , and C_{13} , 42.9, 40.9 $(C_3 \text{ and } C_4)$, 17.3 (C_6) , 15.8 (C_7) , 7.5 (C_9) , 4.0 (C_8) . IR (KBr, cm⁻¹): 1746, 1612 (v_{C=0}). Anal. Calcd (found) for C₆₁H₅₁N₂O₄F₂₄PdSiB: H, 3.48 (3.14); C, 49.59 (49.47); N, 1.90 (2.02).

Reaction of 5 with HSiEt₃. A solution of **5** (23 μ mol, 43 mM) in CD₂Cl₂ (0.53 mL) was treated with HSiEt₃ (10.8 μ L, 67.7 μ mol) at -80 °C, shaken briefly, and placed in the probe of an NMR spectrometer pre-cooled at -81 °C. The NMR probe was warmed at -51 °C, and the solution was monitored periodically by ¹H NMR spectroscopy. The concentration of **5** was determined by integrating the carbomethoxy resonances of **5** (δ 3.69 and 3.43) versus that of the para phenyl proton of the BAr₄⁻ counterion (δ 7.49). A plot of ln[**5**] versus time was linear to 3 half-lives with a first-order rate constant of $k = 1.59 \pm 0.01 \times 10^{-4} \text{ s}^{-1}$ (Figure S2).

Reaction of 6 with HSiEt₃. A solution of **6** (~19 mmol, ~30 mM) in CD₂Cl₂ (0.60 mL) was treated with HSiEt₃ (30 μ mol, 50 mM) at -78 °C, shaken briefly, and placed in the probe of an NMR spectrometer cooled at -80 °C. The NMR probe was warmed at -41 °C, and the solution was monitored periodically by ¹H NMR. After 10 min, resonances corresponding to **6** could no longer be detected (\geq 95% conversion), and resonances corresponding to a 1:1 mixture of **4b** and **3** were observed.

Reaction of 6 with DSiEt₃. DSiEt₃ (5 μ L, 31 μ mol) was added via syringe to an NMR tube containing a solution of **6** (19 μ mol) in CD₂-Cl₂ (0.60 mL) at -80 °C. The tube was shaken briefly and placed in the probe of an NMR spectrometer pre-cooled at -41 °C. Upon complete consumption of **6** (~10 min), the sample was removed from the probe, and the solution was filtered through a plug of Celite and concentrated under vacuum to give **3**-*d*₁. Mass spectral analysis of **3**-*d*₁ indicated an isotopic purity of 98%, and ¹H- and ¹³C NMR analysis

revealed complete (\geq 95%) deuteration of the exocyclic methyl group. ¹³C{¹H} NMR (CDCl₃, 23 °C): δ 17.1 (t, *J* = 19.1 Hz, isotopic shift 300 ppb).

Kinetics of the Silylation of 7. A solution of **7** (22 µmol, 36 mM) and HSiEt₃ (0.21 mmol, 0.36 M) in CD₂Cl₂ (0.60 mL) was monitored periodically by ¹H NMR spectroscopy at -14 °C. The concentration of 7 was determined by integrating the resonance corresponding to one of the carbomethoxy peaks of 7 (δ 4.24) relative to that of the para phenyl resonances of the BAr₄⁻ counterion (δ 7.51). A plot of ln[7] versus time was linear to >4 half-lives (Figure S3), with a pseudofirst-order rate constant of $k_{obs} = 1.33 \pm 0.01 \times 10^{-4} \text{ s}^{-1}$. Employing a similar procedure, pseudo-first-order rate constants for the reaction of HSiEt₃ with 7 at -14 °C in CD₂Cl₂ were obtained at silane concentrations of 0.18, 0.20, 0.38, and 0.93 M (Table 2). For reactions employing initial silane concentrations of 0.18 and 0.20 M, the initial concentration of 7 was lowered to 20 mM. The resulting plot of k_{obs} versus [HSiEt₃] was linear, which provided the second-order rate constant for silvlation of 7 of $k = 3.3 \pm 0.3 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$ (Figure 4).

Reaction of 7 with DSiEt₃. DSiEt₃ (107 μ L, 0.67 mmol) was added via syringe to a solution of **7** (160 mg, 0.13 mmol) in CH₂Cl₂ (1.6 mL) at room temperature, and the resulting solution was stirred for 2 h. The resulting black solution was concentrated under vacuum and chromatographed (SiO₂, hexanes–EtOAc = 24:1) to give *trans*,*trans*-1,1-dicarbomethoxy-2-deuterio-4-(triethylsilylmethyl)-3-methylcyclopentane (**3**-*d*₁') as a colorless oil in 46% yield with 83% isotopic purity as determined by MS analysis. The regio- and stereochemistry of **3**-*d*₁' was determined via ¹H- and ¹³C NMR analysis and by comparison to the spectroscopy of unlabeled **3**; complete assignment of the ¹H NMR resonances of **3** was achieved via combined ¹H–⁻¹H COSY and NOESY analysis. ¹³C{¹H} NMR (CD₂Cl₂, 23 °C): δ 42.0 [t, *J*_{CD} = 20.6 Hz, isotopic shift = 320 ppb, C(1)], 58.3 [s, isotopic shift = 60 ppb, C(5)], 43.8 [s, isotopic shift = 100 ppb, C(2)].

Silane Competition Experiments. A mixture of HSiEt₃ (4.95 mmol) and HSiMe₂R (R = Et, *n*-octyl, OSiMe₃, or Ph) (4.95 mmol) was added via syringe to a solution of **1** (100 μ L, 0.50 mmol) and a catalytic amount of **2b** (12 μ mol) in DCE (10 mL) at 0 °C. The resulting solution was stirred at room temperature until **1** was completely consumed (as determined by GC analysis) to form a mixture of silylated carbocycles **3** and **3a**-**3d**, respectively. The ratio of carbocycles was determined by gas chromatography, correcting for the GC response factors of the carbocycles (Table 3). A second set of experiments employing a 1:1 mixture of HSiMe₂Ph and HSiMe₂(4-C₆H₄R) (R = NMe₂, OMe, CF₃, F) to form a mixture of silylated carbocycles **3d** and **3e**-**3h** was performed in an analogous manner (Table 3).

Catalytic Cyclization/Deuteriosilylation. A solution of **1** (100 μ L, 0.50 mmol), (phen)PdMeCl (8 mg, 24 μ mol), NaBAr₄ (23 mg, 26 μ mol), and DSiEt₃ (300 μ L, 1.9 mmol) in DCE (10 mL) was stirred at room temperature for 30 min. The resulting dark solution was concentrated and chromatographed (SiO₂, hexanes–EtOAc = 24:1) to give **3**-*d*₁ (167 mg, 102%) as a colorless oil. Mass spectral analysis indicated an isotopic purity of 98%, and ¹H- and ¹³C NMR analysis revealed complete (\geq 95%) deuteration of the exocyclic methyl group.

Kinetics of Catalytic Cyclization/Hydrosilylation. CD₂Cl₂ (0.58 mL), NCAr (2.98 μ L, 17.7 μ mol), and 1 (10.0 μ L, 49.5 μ mol) were added sequentially via syringe to a 5-mm NMR tube containing **2b** (9.9 mg, 7.0 μ mol) that was sealed with a septum. After the tube was shaken thoroughly and cooled at -81 °C, HSiEt₃ (16 μ L, 100 μ mol) was added via syringe and the tube was placed in the probe of an NMR spectrometer pre-cooled at -80 °C. The sample was then warmed at -41 °C and monitored periodically by ¹H NMR spectroscopy. The concentration of 1 was determined by integrating the olefinic resonances of 1 at δ 5.08 and 5.11 relative to the aryl para hydrogen resonance of BAr₄⁻ at δ 7.52. A plot of [1] versus time was linear to 3 half-lives (Figure 6), with an observed rate constant of $k_{obs} = 8.20 \pm 0.04 \times 10^{-6}$ M s⁻¹; two identical experiments gave an average value of $k_{obs} =$

 $8.3 \pm 0.6 \times 10^{-6}$ M s⁻¹ (Table 4, entries 1–3). Resonances attributed to the olefinic protons [δ 6.41 (dtd, J = 4.3, 8.4, 16.1 Hz, 1 H, -CH=CH₂), 5.44 (d, J = 9.0 Hz, 1 H, $-CH=CH_2$), 4.22 (d, J = 16.1 Hz, 1 H, $-CH=CH_2$] and carbomethoxy protons [3.68 (s, 3 H), and 3.43 (s, 3 H)] of 5 were observed throughout complete conversion of 1 to 3. Pseudo-zero-order rate constants for the reaction of 1 ($[1]_0 = 85$ mM) and $HSiEt_3$ ([HSiEt_3]₀ = 0.16 M) catalyzed by **2b** were determined as a function of [NCAr], [2b], and temperature, employing a similar procedure (Table 4). The first-order rate constant for the catalytic cyclization/hydrosilylation of 1 ($[1]_0 = 85 \text{ mM}$) and HSiEt₃ ([HSiEt₃]_0 = 0.16 M) at -41 °C was determined from the linear plot of pseudozero-order rate constants versus $[2b]_0$ over the range 0-25 mM (Figure 7). The activation parameters for the reaction of $1 ([1]_0 = 85 \text{ mM})$ and HSiEt₃ ([HSiEt₃]₀ = 0.16 M) catalyzed by **2b** ([**2b**]₀ = 12 mM) were obtained from a plot of $\ln k/T$ versus 1/T over the range -57 to -25°C (Figure 8). The dependence of the rate of catalytic cyclization/ hydrosilylation on silane concentration was determined via iterative fitting of two sets of concentration versus time data for reaction of 1 $([1]_0 = 85 \text{ mM}), 2b ([2b]_0 = 12 \text{ mM}), and HSiEt_3 ([HSiEt_3]_0 = 90)$ mM) in CD₂Cl₂ that contained NCAr (42 mM) at -41 °C to the rate equation depicted in eq 2 employing MacKinetics (version 0.9.1b). This analysis provided a best fit with $k_2 = 7.6 \pm 0.2 \times 10^{-4} \text{ s}^{-1}$ and $k_3 =$

 $0.12 \pm 0.03 \text{ M}^{-1} \text{ s}^{-1}$. To estimate the error limit for k_3 , k_2 was held constant ($k_2 = 7.6 \times 10^{-4} \text{ s}^{-1}$), k_3 was incrementally varied by $\pm 0.01 \text{ M}^{-1} \text{ s}^{-1}$, and the resulting concentration versus time plots were compared visually to the experimental data. The error limit for k_2 determined via iterative fitting was estimated by employing an analogous procedure.

Acknowledgment is made to the NIH (GM59830-01) and PRF (36399-AC4), administered by the American Chemical Society, for support of this research. We thank Mr. Jeff Cross (UNC-Chapel Hill) for obtaining the ¹³C NMR spectra of $5^{-13}C_6$ and $6^{-13}C_6$, and Dr. Tao Pei for synthesizing $1-1,2,3,5,6,7^{-13}C_6$ and $1-3,3,5,5-d_4$.

Supporting Information Available: Syntheses and spectral data for $1a^{-13}C_3$, $1-1,2,3,5,6,7^{-13}C_6$, $5-d_2$, $5-d_4$, $6-d_2$, and $6-d_4$, spectral and analytical data for 3b, 3e, 3f, 3g, and 3h, and representative kinetic plots for reaction of 5 and 7 with HSiEt₃ and for the conversion of 6 to 7.
