Since the 1990s, manganese clusters with large spin ground states have received increasing attention mainly due to their single-molecule magnet behavior.<sup>1,2</sup> A number of high nuclearity homometallic manganese complexes from Mn<sub>16</sub> to Mn<sub>84</sub> have been explored to date.<sup>3–11</sup> However, the rational synthesis of high nuclear heterometallic manganese clusters remains a challenge. Triethanolamine (teaH<sub>3</sub>) is a potentially versatile ligand, and several polynuclear complexes have been recently reported.<sup>12</sup> Enlightened by the facile reactions of zerovalent copper with Co<sup>II</sup>/Zn<sup>II</sup>/Cd<sup>II</sup>/Pd<sup>II</sup> salts and aminoalcohols,<sup>13</sup> we tried to extend such reactions into a new synthetic route to heterometallic manganese clusters. We report herein the synthesis, structure, and magnetic properties of a giant heterometallic Cu<sub>17</sub>Cu<sup>II</sup><sub>13</sub>Mn<sup>II</sup><sub>4</sub>Mn<sup>III</sup><sub>12</sub>Mn<sup>IV</sup><sub>12</sub> cluster, [Cu<sub>17</sub>Mn<sub>28</sub>O<sub>40</sub>-(tea)<sub>12</sub>(HCO<sub>2</sub>)<sub>6</sub>(H<sub>2</sub>O)<sub>4</sub>·36H<sub>2</sub>O (**1**). To our knowledge, **1** is the largest manganese teaH<sub>3</sub> cluster and unprecedented with five metal oxidation states.

The reaction of copper powder, Mn(OAc)<sub>2</sub>·4H<sub>2</sub>O, and teaH<sub>3</sub> in a 1:2:1 ratio in *N,N'*-dimethylformamide (DMF) (30 mL) at 85 °C gave a dark green solution from which dark block crystals of **1** were slowly deposited after several months. The in situ generated formate ligand arises from hydrolysis of DMF which has been previously documented.<sup>14</sup>

The crystal structure of **1**<sup>15</sup> contains a giant [Cu<sub>17</sub>Mn<sub>28</sub>O<sub>40</sub>]<sup>42+</sup> core of *T<sub>d</sub>* symmetry with 4 Cu<sup>I</sup> ions, 13 Cu<sup>II</sup> ions, 4 Mn<sup>II</sup> ions, 12 Mn<sup>III</sup> ions, 12 Mn<sup>IV</sup> ions, 28 μ<sub>4</sub>-O<sup>2-</sup>, and 12 μ<sub>3</sub>-O<sup>2-</sup> ions. Each μ<sub>4</sub>-O<sup>2-</sup> ion joins three Mn ions and one Cu ion (2Mn<sup>III</sup> + Mn<sup>II</sup> + Cu<sup>II</sup> or 2Mn<sup>IV</sup> + Mn<sup>III</sup> + Cu<sup>I</sup> or 3Mn<sup>IV</sup> + Cu<sup>II</sup>), while each μ<sub>3</sub>-O<sup>2-</sup> ion joins one Mn<sup>IV</sup> ion and two Mn<sup>III</sup> ions. There are five metal oxidation states of Mn<sup>2+</sup>, Mn<sup>3+</sup>, Mn<sup>4+</sup>, Cu<sup>+</sup>, and Cu<sup>2+</sup> in **1**, which were established by consideration of bond lengths, bond valence sum (BVS) calculations,<sup>16</sup> charge considerations, and the observation of Jahn–Teller (JT) distortions for the Mn<sup>III</sup> centers. The [Cu<sub>17</sub>Mn<sub>28</sub>O<sub>40</sub>]<sup>42+</sup> core is surrounded by 12 tea<sup>3-</sup> groups, 6 HCO<sub>2</sub><sup>-</sup> groups, and 4 aqua ligands into a neutral cluster (Figure 1).

Each Cu<sup>I</sup> ion is coordinated in a tetrahedral geometry by three μ<sub>4</sub>-O<sup>2-</sup> ions and one aqua ligand. The Cu<sup>II</sup> ions have two different coordination environments: the central Cu<sup>I</sup> ion is coordinated in a perfect tetrahedral environment by 4 μ<sub>4</sub>-O<sup>2-</sup> ions (Cu–O = 1.975–(11) Å), while each of the outer 12 symmetry-related Cu<sup>II</sup> ions is coordinated in a distorted trigonal bipyramidal environment by three alkoxo O atoms in the plane (O–Cu<sup>II</sup>–O = 102.9(3)–127.58(17)°) and one amino N atom and one μ<sub>4</sub>-O<sup>2-</sup> ion at the axial positions (N1–Cu<sup>II</sup>–O4 = 172.6(3)°). Each tea<sup>3-</sup> ligand acts in a μ<sub>4</sub>:η<sup>1</sup>:η<sup>2</sup>:η<sup>2</sup>:η<sup>2</sup> mode to cap an outer Cu<sup>II</sup> atom and bridge one Mn<sup>II</sup> and two

**Figure 1.** Molecular structure (a) and coordination environments (b) of **1**. H atoms and lattice water molecules have been omitted for clarity. Symmetry: (a)  $-y, x, -z$ ; (b)  $y, -x, -z$ ; (c)  $-x, -y, z$ ; (d)  $-y, -x, z$ ; (e)  $-z, -x, y$ ; (f)  $x, z, y$ ; (g)  $-x, y, -z$ ; (h)  $y, z, x$ ; (i)  $z, x, y$ ; (j)  $y, x, z$ ; (k)  $-y, z, -x$ .

**Figure 2.** The adamantane-like Mn<sub>28</sub> cluster containing six [Mn<sup>IV</sup><sub>2</sub>Mn<sup>III</sup><sub>2</sub>O<sub>4</sub>] and four [Mn<sup>IV</sup><sub>3</sub>Mn<sup>II</sup>O<sub>4</sub>] cubanes via sharing all Mn<sup>IV</sup> atoms. Atom color code: Mn<sup>IV</sup>, dark yellow; Mn<sup>III</sup>, navy blue; Mn<sup>II</sup>, magenta; O, red.

Mn<sup>III</sup> ions. There are three oxidation states for the manganese ions, which is uncommon for the manganese clusters.<sup>8,10,17</sup> All Mn centers are six-coordinate (Figure S1), through interactions with five μ<sub>4</sub>-O<sup>2-</sup> ions and one μ<sub>3</sub>-O<sup>2-</sup> ion for Mn1 in an essentially octahedral geometry (average Mn1–O = 1.904 Å), one μ<sub>4</sub>-O<sup>2-</sup> ion, two μ<sub>3</sub>-O<sup>2-</sup> ions, two formate O atoms, and one alkoxide O atom for Mn2 in a tetragonally elongated octahedral geometry (Mn2–O2 and Mn2–O7 = 2.221(6) and 2.143(8) Å constituting the JT axis), and three μ<sub>4</sub>-O<sup>2-</sup> ions and three alkoxide O atoms for Mn3 forming a distorted trigonal prism (average Mn3–O = 2.190 Å), respectively.

The most striking structural feature is that all the 28 Mn ions are bridged by the 28 μ<sub>4</sub>-O<sup>2-</sup> and 12 μ<sub>3</sub>-O<sup>2-</sup> ions into 6 Mn<sup>III</sup><sub>2</sub>Mn<sup>IV</sup><sub>2</sub>O<sub>4</sub> cubanes (Mn–O–Mn = 93.6(2)–102.5(2)°) and 4 Mn<sup>II</sup>Mn<sup>IV</sup><sub>3</sub>O<sub>4</sub> cubanes (Mn<sup>II</sup>–O–Mn<sup>IV</sup>, Mn<sup>IV</sup>–O–Mn<sup>IV</sup> = 97.5(3)–99.9(3)°), which are further joined to be a cubane-based manganese cage via sharing all the 12 Mn<sup>IV</sup> ions (Figure 2). Such a structure is unprecedented in the known high nuclearity Mn clusters. Finally, the connectivity of the [Cu<sub>17</sub>Mn<sub>28</sub>O<sub>40</sub>]<sup>42+</sup> core can be precisely

**Figure 3.** Plot of reduced magnetization ( $M/N\beta$ ) versus  $H/T$  for **1** in the temperature range of 1.8–4.0 K (5 kG (orange), 10 kG (dark green), 20 kG (brown), 30 kG (dark red), 40 kG (teal), 50 kG (dark blue), 60 kG (green), 70 kG (red)). Solid lines represent best theoretical fit. Inset illustrates  $\chi_m T$  versus  $T$  plot for complex **1** from 1.8 to 300 K (1 kG (black), 10 kG (red), 50 kG (blue)).

**Figure 4.** AC magnetic measurements for **1** at  $H_{ac} = 5$  G and  $H_{dc} = 0$ .

described by noting that the central  $\text{Cu}^{\text{I}}$  ion connects four  $\text{Mn}^{\text{II}}\text{-Mn}^{\text{IV}}_3\text{O}_4$  cubanes into a tetrahedral array. Six  $\text{Mn}^{\text{III}}_2\text{Mn}^{\text{IV}}_2\text{O}_4$  cubanes are located on the midlines of the six edges of the tetrahedron and connect the four  $\text{Mn}^{\text{II}}\text{Mn}^{\text{IV}}_3\text{O}_4$  cubanes via the 12  $\text{Mn}^{\text{IV}}$  corners into an adamantane-like cage. Each of the four  $[\text{Cu}^{\text{I}}(\text{H}_2\text{O})]$  groups (on 3-fold axes) connects three  $\text{Mn}^{\text{III}}_2\text{Mn}^{\text{IV}}_2\text{O}_4$  cubanes, and the outer 12  $\text{Cu}^{\text{II}}$  ions connect the  $\text{Mn}_{28}$  cluster via the remaining  $\mu_4\text{-O}^{2-}$  sites.

DC magnetic susceptibility data were collected in fields ranging from 70 to 1 kG in the temperature range of 1.8–300 K (Figure 3). The reduced magnetization ( $M$ ) versus  $H/T$  data cannot be fit to one state experiencing axial zero-field splitting  $D\hat{S}_z^2$  (in fact,  $T_d$  symmetry does not allow this). The  $\chi T$  versus  $T$  data (inset Figure 3) taken at fields of less than 1 kG show a maximum of  $\sim 325$   $\text{cm}^3 \text{mol}^{-1} \text{K}$ . This suggests a  $S = 5/2$  ground state in small fields, which is reasonable given that the  $\text{Mn}^{\text{III}}\cdots\text{Mn}^{\text{III}}$ ,  $\text{Mn}^{\text{IV}}\cdots\text{Mn}^{\text{IV}}$ , and  $\text{Mn}^{\text{III}}\cdots\text{Mn}^{\text{IV}}$  interactions within the cubane units are expected to be ferromagnetically coupled, while the  $\text{Mn}^{\text{II}}\cdots\text{Mn}^{\text{IV}}$ ,  $\text{Cu}^{\text{II}}\cdots\text{Mn}^{\text{III}}$ , and  $\text{Cu}^{\text{II}}\cdots\text{Mn}^{\text{IV}}$  interactions are antiferromagnetic which would give  $S = 12S_{\text{Mn(IV)}} + 12S_{\text{Mn(III)}} - 4S_{\text{Mn(II)}} - 13S_{\text{Cu(II)}} = 5/2$ . The non-superimposability of isofields in the reduced magnetization versus  $H/T$  plot usually indicates the presence of axial zero-field interactions. However, we have fit all the data (solid lines in Figure 3) assuming that there is a  $S = 6/2$  excited state lying 5 K above the  $S = 5/2$  ground state. The fit is quite good, and it is important to emphasize that the model has no zero-field splitting for either of the states. This is consistent with the  $T_d$  symmetry that precludes the  $D\hat{S}_z^2$  term in the spin Hamiltonian. High-frequency EPR studies have been initiated to verify the two spin state model.

AC magnetic susceptibility data for **1** (Figure 4) do show a frequency-dependent out-of-phase signal; however, only the onset

of the signal is seen. Lower temperature AC data or micro-SQUID data are needed to establish whether this interesting complex **1** functions as a single-molecule magnet.

In summary, we have established an approach to generate a giant heterometallic mixed-valent  $\text{Cu}^{\text{I}}/\text{Cu}^{\text{II}}/\text{Mn}^{\text{II}}/\text{Mn}^{\text{III}}/\text{Mn}^{\text{IV}}$  cluster which contains an unprecedented adamantane-like  $\text{Mn}_{28}$  core connected wholly by  $\text{Mn}_4\text{O}_4$  cubane units and exhibits unusual magnetic properties.
