Received April 30, 2007; E-mail: wangjb@pku.edu.cn

Palladium catalyzed cross-coupling reaction has been developed into one of the most powerful methods for the formation of C-C bonds. Recently, remarkable progress has been made in the Pdcatalyzed cross-coupling reactions with carbon nucleophiles derived from active methylene compounds, 1d ketones, 2 esters, 3 amides, 4 and nitriles.<sup>5</sup> Hydrazones have also been applied in this type of reactions as acyl anion nucleophiles.<sup>6</sup> In connection with our interest in the chemistry of diazo compounds as nucleophiles,7 we have conceived that α-diazocarbonyl compounds, which are commonly used as carbene precursors,8 may be utilized as carbon nucleophiles in Pdcatalyzed coupling reactions. Diazo carbon bears a partial negative charge and thus has considerable nucleophilicity;9 however, to the best of our knowledge, diazo compounds have not been directly used as partners in Pd-catalyzed cross-coupling reactions. 10 This may be attributed to the general belief that diazo decomposition should occur readily upon complexation with transition metals.<sup>8,11</sup> Herein we report that ethyl diazoacetate (EDA) undergoes efficient Pd-catalyzed cross-coupling with aryl or vinyl iodides. Moreover, carbonylation occurs prior to the coupling if the reaction is carried out under an atmosphere of CO.

An initial attempt to couple EDA with ethyl (Z)-3-iodopropenoate (1a) using Et<sub>3</sub>N as base and Pd(OAc)<sub>2</sub> as catalyst in CH<sub>2</sub>Cl<sub>2</sub> resulted in rapid diazo decomposition (Table 1, entry 1). Pd<sub>2</sub>(dba)<sub>3</sub> also decomposed EDA (entry 2). To our delight, with PdCl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub> the reaction afforded cross-coupling product, albeit in low yield (entry 3). The yield could be slightly improved by Pd(PPh<sub>3</sub>)<sub>4</sub> (entry 4). Other reaction parameters were then screened with this catalyst. Increasing the catalyst loading could further improve the yield (entry 5). The reaction seemed more favored in polar solvents such as MeCN, DMF, and acetone, but MeOH and DMSO resulted in diminished yields (entries 10, 11). Inorganic bases of Cs<sub>2</sub>CO<sub>3</sub>, K<sub>2</sub>-CO<sub>3</sub> were found unsuitable in this reaction (entries 12, 13). The introduction of 1 equiv of n-Bu<sub>4</sub>NBr as additive significantly improved the reaction (entry 15).12 However, Pd(0) catalyst containing more electron-rich phosphine ligands were found not effective in this reaction (entries 16, 17).

Moreover, it was noteworthy that without Pd(0) catalyst no coupling product could be observed (entry 18). This experiment rules out the possibility of a conjugate addition—elimination mechanism for the formation of 2a.<sup>13</sup>

A series of vinyl iodides were then subjected to the optimized reaction conditions (Table 1, entry 15). The reaction gave cross-coupling products in moderate to good yields (Table 2). The strong electron-withdrawing substituent at the double bond was found necessary for this reaction since the reaction with  $\beta$ -iodo styrene gave no cross-coupling product. Besides, it was noted that the reaction proceeded with retention of configuration at the double bond.

Next we conceived to extend the coupling reaction to aryl halides. However, when the above reaction conditions were applied to iodobenzene, the expected cross-coupling product was not obtained.

Table 1. Pd-Catalyzed Cross-Coupling of Iodide 1a with EDA

entry	catalyst (mol %)	solvent	base	yield (%) <sup>a</sup>
1	Pd(OAc) <sub>2</sub> (2.5)	CH <sub>2</sub> Cl <sub>2</sub>	Et <sub>3</sub> N	h
2	Pd <sub>2</sub> (dba) <sub>3</sub> (2.5)	CH <sub>2</sub> Cl <sub>2</sub>	Et <sub>3</sub> N	b
3	PdCl <sub>2</sub> (PPh <sub>3</sub> ) <sub>2</sub> (2.5)	CH <sub>2</sub> Cl <sub>2</sub>	Et <sub>3</sub> N	27
4	Pd(PPh <sub>3</sub> ) <sub>4</sub> (2.5)	CH <sub>2</sub> Cl <sub>2</sub>	Et <sub>3</sub> N	41
5	$Pd(PPh_3)_4(5)$	$CH_2Cl_2$	Et <sub>3</sub> N	62
6	$Pd(PPh_3)_4(5)$	MeCN	Et <sub>3</sub> N	70
7	$Pd(PPh_3)_4(5)$	DMF	$Et_3N$	66
8	$Pd(PPh_3)_4(5)$	$Me_2C=O$	$Et_3N$	79
9	$Pd(PPh_3)_4(5)$	$Et_2O$	$Et_3N$	47
10	$Pd(PPh_3)_4(5)$	MeOH	$Et_3N$	40
11	$Pd(PPh_3)_4(5)$	DMSO	$Et_3N$	40
12	$Pd(PPh_3)_4(5)$	MeCN	$Cs_2CO_3$	26
13	$Pd(PPh_3)_4(5)$	MeCN	$K_2CO_3$	c
14	$Pd(PPh_3)_4(5)$	MeCN	DBU	c
15	$Pd(PPh_3)_4(5)/n-Bu_4NBr$	$Me_2C=O$	$Et_3N$	86
$16^d$	Pd <sub>2</sub> (dba) <sub>3</sub> (2.5)/dppb (5)/n-Bu <sub>4</sub> NBr	$Me_2C=O$	$Et_3N$	11
17	$Pd_2(dba)_3 (2.5)/^tBu_3P(5)/n-Bu_4NBr$	$Me_2C=O$	$Et_3N$	trace
18	$n ext{-}\mathrm{Bu}_4\mathrm{NBr}^e$	$Me_2C=O$	$Et_3N$	c

 $<sup>^</sup>a$  Isolated yield.  $^b$  Diazo decomposition occurred rapidly to give a complex mixture.  $^c$  **2a** was not detected.  $^d$  dppb = 1,4-bis(diphenylphosphino)butane.  $^e$  No Pd catalyst.

<sup>&</sup>lt;sup>a</sup> Isolated yield after column chromatography.

The reaction occurred smoothly with meta and para substituted aryl iodides to afford the corresponding aryl diazoacetate. The contrasting results obtained with p-NO2 and p-MeO substituted substrates indicated significant influence of electronic effects on the reaction (entries 8, 9). On the other hand, the reactions with ortho substituted aryl iodides failed to afford the corresponding coupling products, which revealed that the reaction was also affected by steric hindrance (entries 10, 11). It was also noted that aryl bromides were less reactive in this reaction (entries 12, 13).

Encouraged by the results with vinyl and aryl iodides, we further investigated the carbonylation with CO in this cross-coupling process. After optimizing the reaction conditions, we found that Et<sub>3</sub>N was the suitable base for this purpose. Typical results are summarized in Table 4. The carbonylation followed by crosscoupling afforded  $\beta$ -keto  $\alpha$ -diazocarbonyl compounds in moderate yields. The slightly diminished yields as compared with direct coupling reaction were attributed to the decreased reactivity of the catalyst under this condition, which resulted in long reaction time and incomplete reaction. Again, ortho substituted aryl iodide afforded only trace amount of coupling product (entry 5).

The reaction mechanism for this reaction is shown in Scheme 1. Oxidative addition of  $Pd(0)L_n$  with aryl or vinyl iodide affords the Pd(II) intermediate A. Substitution of the iodo by diazo anion, which is derived from deprotonation of EDA, provides the intermediate C (path a). Alternatively, EDA coordinates to Pd(II) intermediate A to form complex B, from which proton is removed by base to afford C (path b). A Remarkably, nitrogen extrusion,

Scheme 1. Mechanistic Rationale

which is a very facile process for transition metal-complexed diazo compounds, 8,11 does not occur from complex B. Finally reductive elimination of the intermediate C gives the cross-coupling product and regenerates the catalyst. In the presence of CO, prior to the reaction with EDA the CO insertion occurs from intermediate A to afford **D**, from which reaction with EDA/Et<sub>3</sub>N followed by reductive elimination leads to  $\beta$ -keto  $\alpha$ -diazocarbonyl compounds (path c).

In summary, α-diazocarbonyl compound has been utilized for the first time as cross-coupling partner in Pd-catalyzed reaction. The reaction provides a novel approach to introduce diazo functionality to organic compounds.
