# Probing the Planar Tetra-, Penta-, and Hexacoordinate Carbon in Carbon-Boron Mixed Clusters 

Yong Pei and Xiao Cheng Zeng*<br>Department of Chemistry and Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, Lincoln, Nebraska 68588

Received September 14, 2007; E-mail: xczeng@phase2.unl.edu

#### Abstract

The concept of planar hypercoordinate (e.g., penta- and hexacoordinate) carbons is intriguing [Exner, K.; Schleyer, P. v. R. Science 2000, 290, 1937] as it is neither compatible with the standard rule of three-dimensional chemical bonding nor with the maximum tetracoordination. Herein we undertake a comprehensive study of the planar tetra- (ptC), penta- (ppC), and hexacoordinate carbon (phC) by covering the whole family of carbon-boron mixed clusters $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ and their anions. The potential energy surface of every carbon-boron cluster is sampled by using the basin-hopping global search algorithm coupled with ab initio geometry optimization. A large number of planar tetra-, penta-, and hexacoordinate carbon (local-minimum) structures are obtained. Several structures such as the phC consisting of $\mathrm{C}_{2} \mathrm{~B}_{5}, \mathrm{C}_{2} \mathrm{~B}_{5}{ }^{-}$, etc. are reported for the first time. In particular, a ptC corresponding to the global minimum of $\mathrm{CB}_{4}$ is revealed, which appears to be highly stable for future synthesis. The boron-centered isomers are generally the more stable structures for planar multicoordinate carbons (ptC, ppC, and phC). The planar tetra-, penta-, and hexacoordinate boron are the prevalent structural motifs in low-lying isomers of the carbon-boron clusters. However, stability of the ptC and ppC units can be reinforced over the boron-centered isomers by attaching proper hydrocarbon unit -(CH) $)_{n}$ to form the so-called "hyparenes" [Wang, Z. X.; Schleyer, P. v. R. Science 2001, 292, 2465]). A new hyparene molecule is suggested for future synthesis of novel planar hypercoordinate carbon compounds.

## 1. Introduction

The spatial tetrahedral bonding of tetracoordinate carbon was first recognized by J. H. van't Hoff and J. A. Le Bel in 1874. ${ }^{1,2}$ Since then, tetracoordinate carbon has become a textbook concept. In 1970, R. Hoffmann et al. ${ }^{3}$ inquired whether it is conceivable to synthesize new coordination carbon geometry distinct from the tetracoordinate carbon, such as the planar tetracoordination carbon ( ptC ) (known as the anti-van't Hoff/ Lebel compound). Because the concept of the planar tetracoordination carbon not only is of fundamental interest but also has important implication in developing new materials, molecular frameworks containing the anti-van't Hoff/Lebel unit has attracted intensive interests over the past 30 years. ${ }^{4}$ Despite of much efforts in both experimental and theoretical research,

[^0]realization of the anti-van't Hoff/Lebel complex in the laboratory remains a challenging task. This is largely because the conversion of a carbon from inherently tetrahedral coordination to planar tetracoordination is an energetically expensive process. ${ }^{3,5}$

From analyzing the molecular orbital (MO) sequence of the planar methane $\left(D_{4 h}\right)$, Hoffmann suggested that the key to stabilizing ptC is to delocalize the lone pair electrons on the ptC center, known as the electronic stabilization mechanism. ${ }^{3}$ The introduction of $\sigma$-donating $/ \pi$-accepting substituents or the incorporation of lone pair into the $\pi$-electron delocalization system may stabilize the ptC center more efficiently. ${ }^{3}$ Motivated by this mechanism, a number of stable and simply structured ptC compounds were predicted theoretically. ${ }^{4 \mathrm{~h}, \mathrm{i}, 6-10}$ A pioneer

[^1]work was the design of a series of lithio-substituted ptC molecules by Schleyer, Pople, and co-workers in 1976. ${ }^{6 \mathrm{a}}$ The electropositive metal ligands (e.g., -Li ) were found particularly effective to stabilize the ptC. ${ }^{4 \mathrm{~h}}$ The first successful synthesis of molecules containing ptC was reported in 1977, where the ptC is coordinated with two vanadium $(\mathrm{V})$ atoms. ${ }^{11}$ To date, most ptC compounds synthesized in the laboratory are organometallic with transition metal. The group IVB transition-metal-based bent metallocenes, i.e., titanocene, zirconocene, and hafnocene, are found especially effective for making carbon compounds containing unusual coordinate structures. ${ }^{12}$

The smallest molecular system that can accommodate a planar tetracoordinate carbon is the penta-atomic molecule. A pentaatomic ptC molecule $\left(\mathrm{CAl}_{2} \mathrm{Si}_{2}\right)$ was proposed by Boldyrev and Schleyer in $1991 .{ }^{13}$ Later, the $\mathrm{CAl}_{2} \mathrm{Si}_{2}$, as well as $\mathrm{CAl}_{2} \mathrm{Ge}_{2}$ and $\mathrm{CGa}_{2} \mathrm{Si}_{2}$, were studied by Boldyrev and Simons using highlevel ab initio calculations. ${ }^{14}$ It was concluded that the C atom in the global minimum structures of $\mathrm{CAl}_{2} \mathrm{Si}_{2}, \mathrm{CAl}_{2} \mathrm{Ge}_{2}$, and $\mathrm{CGa}_{2} \mathrm{Si}_{2}$ is in a planar tetracoordinate arrangement. ${ }^{14}$ Shortly after these findings, a joint theoretical/experimental study reported the $\mathrm{CAl}_{4}{ }^{2-}, \mathrm{CAl}_{4}{ }^{-}, \mathrm{CAl}_{3} \mathrm{Si}^{-}$, and $\mathrm{CAl}_{3} \mathrm{Ge}^{-}$species, ${ }^{15}$ the first ptC moieties confirmed by the experiment. A new family of pure carbon ptC systems, namely the dianion $\mathrm{C}_{5}{ }^{2-}$, were shown theoretically by Merino et al. in 2003. ${ }^{16,17}$ The $\mathrm{C}_{5}{ }^{2-}$ can be further stabilized by binding with alkaline metals, such as the formation of $\mathrm{Li}_{2}{ }^{2+} \mathrm{C}(\mathrm{C} 4)^{2-}$ salt ${ }^{16 \mathrm{a}}$ in which the ptC moiety is intact. However, the dianion $\mathrm{C}_{5}{ }^{2-}$ species is yet to be realized in the laboratory. Some ptC-containing one-, two-, and threedimensional supermolecular structures were also proposed theoretically. ${ }^{6 e, 18,19}$

Besides the electronic stabilization mechanism, an alternative way to stabilizing the planar tetracoordinate carbon is to incorporate a ptC moiety such as the $\mathrm{CC}_{4}$ or $\mathrm{CB}_{4}$ into a rigid steric system. ${ }^{20-28}$ However, it is challenging to realize this way of molecular design in the laboratory since the molecular skeleton would be under intense strain. The fenestranes might

[^2]be promising precursors toward the synthesis of anti-van't Hoff/ Lebel structures. ${ }^{4 \mathrm{~d}, 22}$

Besides the ptC, more fascinating forms of planar hypercoordinate carbon, e.g., the planar penta- and hexacoordinate carbon, were first suggested by Schleyer and co-workers based on high-level ab initio molecular orbital calculations. ${ }^{29,30}$ The $\mathrm{CB}_{6}{ }^{2-}, \mathrm{CB}_{6} \mathrm{H}_{2}$, and three isomers of $\mathrm{C}_{3} \mathrm{~B}_{4}$ were shown to be stable local minima, which contain planar hexacoordinate carbon (phC). ${ }^{29}$ Moreover, an unusual heptacoordinate planar carbon structural unit, $\mathrm{CB}_{7}^{-}$, was also proven to be a stable local minimum. ${ }^{30}$ By linking the $-\mathrm{C}_{3} \mathrm{~B}_{3}-,-\mathrm{C}_{2} \mathrm{~B}_{4}-$, or $-\mathrm{CB}_{5}-$ unit with a hydrocarbon unit, $-(\mathrm{CH})_{n}-$, a new family of "hyparene" molecules that contain the ptC moiety was proposed. ${ }^{30}$ Very recently, varieties of phC-containing molecules were also suggested. ${ }^{31}$ These previous studies have greatly advanced the notion of planar penta-, hexa-, and even heptacoordinate carbon and broadened the conventional view of the bonding capabilities of carbon atoms. Nevertheless, we are aware that the feasibility of the planar carbon structures is still based on theoretical prediction. Thus far, few experimental data are available on structures of carbon-boron mixed clusters. ${ }^{32}$ One recent experimental/theoretical photoelectron spectroscopy study showed that the planar heptacoordinate carbon structure $\left(\mathrm{CB}_{7}^{-}\right)$is not the global minimum. ${ }^{33}$

In this work, we undertake a systematic theoretical study to search for the planar tetra-, penta-, and hexacoordinate carbons by covering the whole family of small-sized carbon-boron mixed clusters $\mathrm{C}_{m} \mathrm{~B}_{n}$ and their anions $\mathrm{C}_{m} \mathrm{~B}_{n}{ }^{-}(m=1-4$ and $n$ $=4-8$ ). Toward this end, we combined a global minimum search technique (the basin-hopping algorithm) ${ }^{34}$ with the density-functional theory (DFT) ${ }^{35}$ geometry optimization. Previous theoretical studies have shown ample evidence of stable $\mathrm{ptC}, \mathrm{ppC}$, and phC structures in the clusters $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8} .{ }^{29-31,36-38}$ Using the basin-hopping algorithm, ${ }^{34}$ we obtained the lowestenergy structures (global minima) of every carbon-boron cluster, as well as all the low-lying and a number of high-lying metastable structures. Our major findings are summarized as

[^3]follows: (i) A new global minimum ptC molecule, $\mathrm{CB}_{4}$, is revealed. It is predicted to be highly stable and thus a promising candidate for future synthesis. (ii) It is found that the planar tetra-, penta-, hexa-, and octacoordinate borons are dominant structural motifs in the global minima of $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ clusters and anions. (iii) More than 30 forms of $\mathrm{ptC}, \mathrm{ppC}$, and phC structural motifs are observed; most of them, however, have relatively high energy. (iv) A rule to describe the structural feature of boron in the $\mathrm{ptC}, \mathrm{ppC}$, and phC units is found. This general rule can be useful for the search of other planar multicoordinate carbon ( pmC ) structures. (v) The relative thermodynamic stabilities of carbon-boron mixed clusters containing pmC are evaluated for the first time. It is found that the exchange of the central C atom with a perimeter B atom in pmC can significantly lower the total energy (except for the $\mathrm{CB}_{4}$ ). Further calculation, however, suggests that the stability of the ptC and ppC units can be significantly enhanced over the boron-centered isomers by attaching a proper hydrocarbon unit $-(\mathrm{CH})_{n}$ - to form the hyparenes structures. ${ }^{30}$

## 2. Computational Methods

We sample the potential energy surface of each carbon-boron cluster by means of the basin-hopping ( BH ) algorithm ${ }^{34}$ combined with DFT geometry optimization. ${ }^{35}$ Briefly, the BH algorithm removes relatively low barriers separating the local minima of the potential energy surface and thus effectively converts portions of the potential energy surface into a multidimensional staircase. ${ }^{34}$ Effectiveness of the BH algorithm has been demonstrated previously. ${ }^{39}$ Here we calculate the potential energy and energy gradient using a DFT method with a gradientcorrected functional, namely, the Perdew-Burke-Ezerhof (PBE) exchange-correlation functional ${ }^{41}$ implemented in the DMol3 program (a DFT program distributed by Accelrys, Inc., San Diego; see ref 40). The all-electron d-polarization function including double-numerical basis set (DND) is adopted. In the BH search, both the singlet and triplet energies for the close-shell clusters are examined.

We identify the lowest-energy isomer of a carbon-boron cluster in three steps: (1) all low-lying isomers (obtained from DMol3 total energy calculations) with their energy value within $46 \mathrm{kcal} / \mathrm{mol}(\sim 2.0$ eV ) from the lowest-energy isomer are collected for further geometry optimization and frequency calculation at the B3LYP/6-311+G(d,p) level of theory using the Gaussian03 package; ${ }^{42,43}$ (2) the single-point energies of top six lowest-lying isomers are calculated using a coupledcluster method ${ }^{44}[\operatorname{CCSD}(\mathrm{~T}) / 6-311+\mathrm{G}(\mathrm{d}, \mathrm{p})]$; (3) those low-lying isomers with very close energies [less than $3 \mathrm{kcal} / \mathrm{mol}$ in energy difference in the $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(\mathrm{d}, \mathrm{p})$ calculation] are further examined via the $\operatorname{CCSD}(\mathrm{T}) /$ cc-pVTZ calculation. We note that the mid-level $\operatorname{CCSD}(\mathrm{T}) /$ $6-311+G(d, p)$ calculation yields a qualitatively consistent energy

[^4]ranking compared to that from the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{cc}-\mathrm{pVTZ}$ calculation for the carbon-boron clusters (see Supporting Information).

## 3. Results and Discussion

Table 1 displays the predicted global minima, M1-M20 and $\mathbf{M 1}{ }^{-}$- M20 ${ }^{-}$, for the 20 mixed carbon-boron clusters $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ and their anions. Here, the $\mathrm{B}: \mathrm{C}$ ratio ranges from 1 to 8 . It is found that all the lowest-energy structures of the close-shell species are in the singlet state. Almost all the lowest-energy structures [except for $\mathrm{CB}_{4}{ }^{-}\left(\mathbf{M 1}^{-}\right), \mathrm{CB}_{6}(\mathbf{M 3})$, and $\mathrm{C}_{3} \mathrm{~B}_{6}{ }^{-}\left(\mathbf{M 1 3}^{-}\right)$, and $\left.\mathrm{C}_{4} \mathrm{~B}_{5}^{-}\left(\mathbf{M 1 7}{ }^{-}\right)\right]$are planar in geometry. It can be seen from Table 1 that the planar tetra-, penta-, and hexacoordinate boron are prevalent structural motifs for the carbon-boron clusters (M2-M20 and M1 ${ }^{-}$- M20 ${ }^{-}$). Only CB $_{4}$ (M1 in Table 1) contains a ptC unit. All other $\mathrm{ptC}, \mathrm{ppC}$, and phC structural isomers are local minima.
3.1. $\mathrm{CB}_{4}$ : An Alternative Planar Tetracoordinate Carbon Compound. The $\mathrm{CB}_{4}$ (M1) has a unique ptC structure. Although many ptC-containing compounds have been predicted theoretically, ${ }^{4 \mathrm{~h}}$ only a few have been confirmed by experiment, such as $\mathrm{CAl}_{4}{ }^{2-}, \mathrm{CAl}_{4}^{-}$, and $\mathrm{CSiAl}_{3}{ }^{-}$among others. ${ }^{15}$ The global minima of $\mathrm{CAl}_{4}{ }^{2-}, \mathrm{CAl}_{4}^{-}$, and $\mathrm{CSiAl}_{3}{ }^{-}$exhibit the same structural feature, that is, the ptC center is stabilized by a closed four-membered ring, just like the $\mathrm{Al}_{4}$ four-membered ring. ${ }^{13-15}$ The structure of $\mathrm{CB}_{4}$ (M1) differs from that of $\mathrm{CAl}_{4}{ }^{2-}, \mathrm{CAl}_{4}{ }^{-}$, and $\mathrm{CSiAl}_{3}{ }^{-}$because the $\mathrm{B}-\mathrm{B}$ bonds are too short to form a closed four-membered ring to accommodate the ptC center. The four boron atoms actually locate on one side of the carbon atom in the $\mathrm{CB}_{4}$. Hence, the $\mathrm{CB}_{4}$ can be viewed as a cut from the $\mathrm{CB}_{6}{ }^{2-}$ planar structure (where the six boron atoms form a sixmembered ring to enclose the phC center) ${ }^{29}$ by half.

Table 2 displays three low-lying isomers $(\mathbf{A}-\mathbf{C})$ of $\mathrm{CB}_{4}$ along with the relative energies of the isomers at higher levels of theory. The coupled-cluster calculation at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{cc}-\mathrm{pVTZ}$ level shows that the $C_{2 v}$ isomer $\mathbf{A}$ is the lowest-energy structure rather than the isomer $\mathbf{C}$ as suggested from the DFT/B3LYP calculation. Note that the isomer $\mathbf{C}$ is at triplet spin state. The relative energy of the $T_{d}$ isomer of $\mathrm{CB}_{4}$ is also shown in Table 2. One can see that the ptC structure greatly favors the spatial $T_{d}$ isomer.

From an analysis of the molecular orbital of $\mathrm{CAl}_{4}{ }^{2-}$, Boldyrev et al. concluded that the unbalanced bonding and antibonding interactions among the -Al ligands lead to the first-order JahnTeller distortion for the $T_{d}$ structure. ${ }^{14}$ The 17 - and 18 -valence electron systems were suggested to be the most promising for the occurrence of planar structure. ${ }^{14,15 c}$ In our case, the $\mathrm{CB}_{4}$ only possesses 16 -valence electrons. We attribute the electrondeficient nature of the boron to the stability of the neutral $\mathrm{CB}_{4}$. The delocalization of the lone pair has been considered as a key factor to stabilizing the central $\mathrm{ptC} .{ }^{3}$ According to the molecular orbital pictures displayed in Figure 1, the lone pair on the central carbon atom of the $\mathrm{CB}_{4}$ is delocalized by the surrounding boron atoms, as in the case of $\mathrm{CAl}_{4}{ }^{2-15 b}$ and $\mathrm{C}(\mathrm{C})_{4}{ }^{2-} .{ }^{17 a}$ A significant contribution of the perpendicular p orbital of the central ptC atom to the highly delocalized $\pi$ orbital (HOMO-4, $1 \mathrm{~b}_{1}$ ) is seen (Figure 1). The total number of $\pi$-electrons in $\mathrm{CB}_{4}$ is two, satisfying the Hückel $(4 n+2)$ $\pi$-electron rule. The nucleus-independent chemical shift (NICS) values, which are -7.24 ppm at the molecular center and -20.06 ppm at $0.5 \AA$ above the molecular center [calculated at

[^5]B3LYP/6-311+G(d,p) level], confirm the aromaticity nature of the $\mathrm{CB}_{4}$ molecule. Furthermore, the large cohesive energy of $120.51 \mathrm{kcal} / \mathrm{mol}$ [calculated at the level of $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}-$ $(\mathrm{d}, \mathrm{p})]$ suggests relatively high stability of the $\mathrm{CB}_{4}$ molecule.

On the other hand, for the 17 -electron anion $\mathrm{CB}_{4}^{-}$, the ptC structure is not observed (cf. Table 1 and the Supporting Information for the low-lying energy isomers of the $\mathrm{CB}_{4}{ }^{-}$).

Table 2. Low-Energy Isomers of the $\mathrm{CB}_{4}$ Cluster and Their Relative Energies

|  | Low-lying Isomers A $\sim \mathbf{C}$ |  |  | Spatial Coordinate |

Figure 1. Molecular orbitals of the global minimum $\mathrm{CB}_{4}$.
Although the bulk crystal of boron carbide $\mathrm{CB}_{4}$ is a wellknown hard material, ${ }^{45}$ we are unaware of any structural data for the $\mathrm{CB}_{4}$ molecule. Liu et al. recently observed structural conversion among various $\mathrm{CB}_{4}$ isomers. ${ }^{38}$ We certainly hope that the predicted lowest-energy $\mathrm{CB}_{4}$ molecule can be isolated in future experiments. For that purpose, we present the calculated infrared spectrum of the $\mathrm{CB}_{4}$ in the Supporting Information.
3.2. Structural Evolution of $\mathrm{C}_{m} \mathrm{~B}_{n}$ and $\mathrm{C}_{m} \mathrm{~B}_{n}{ }^{-}(m=1-4$; $n=4-8)$ Clusters. In the global minima M2-M20 and M1 ${ }^{-}$$\mathbf{M 2 0}{ }^{-}$(cf. Table 1), the carbon atom generally occupies the peripheral position of the clusters with only two- or three-fold coordination. A change of position of the peripheral carbon atom

[^6]will affect relative stabilities of the clusters. For example, the isomers M2-iso, M7--iso, M8-iso, M13 ${ }^{-}$-iso, and M14--iso are slightly higher in energy than the global minima M2, M7 ${ }^{-}$, M8, M13 ${ }^{-}$, and M14 ${ }^{-}$, respectively (cf. Table 1).

The series of $\mathrm{CB}_{n}$ and $\mathrm{C}_{2} \mathrm{~B}_{n}(n=4-8)$ are boron-rich carbon-boron clusters. It has been shown that the carbon-rich carbon-boron clusters, $\mathrm{C}_{n} \mathrm{~B}^{-}(n=1-13)$, have floppy linear or cyclic structures, similar to those of the pure carbon clusters $\left(\mathrm{C}_{n}{ }^{-}\right) .{ }^{46,47}$ Here, the neutral $\mathrm{CB}_{4}$ (M1), $\mathrm{CB}_{5}$ (M2), $\mathrm{CB}_{6}$ (M3), $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{4}$ (M6), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) and anions $\mathrm{CB}_{5}^{-}\left(\mathbf{M} \mathbf{2}^{-}\right), \mathrm{CB}_{7}^{-}\left(\mathbf{M} 4^{-}\right), \mathrm{C}_{2} \mathrm{~B}_{4}^{-}\left(\mathbf{M 6}^{-}\right)$show structural similarities to the pure boron clusters. For example, the lowestenergy structure $\mathrm{CB}_{4}$ (M1) has the same skeleton structure as that of the $\mathrm{B}_{5}$ cluster. ${ }^{48}$ The lowest-energy structures $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4}{ }^{-}\right), \mathrm{CB}_{8}(\mathbf{M 5})$, and $\mathrm{C}_{2} \mathrm{~B}_{6}(\mathbf{M 8})$ are molecular-wheel like, similar to those of $\mathrm{B}_{8}, \mathrm{~B}_{8}{ }^{2-}$, and $\mathrm{B}_{9}{ }^{-}$, respectively. ${ }^{49}$ Some other analogies, such as those between $\mathrm{CB}_{5}$ (M2) and $\mathrm{B}_{6},{ }^{50} \mathrm{CB}_{5}{ }^{-}$ (M2 ${ }^{-}$), $\mathrm{C}_{2} \mathrm{~B}_{4}$ (M6), $\mathrm{C}_{2} \mathrm{~B}_{4}^{-}\left(\mathbf{M 6}^{-}\right)$, and $\mathrm{B}_{6}{ }^{-, 50}$ as well as between $\mathrm{CB}_{6}(\mathbf{M 3})$ and $\mathrm{B}_{7}{ }^{48}$ are also found, suggesting that the structures of the boron-rich carbon-boron clusters $\mathrm{CB}_{n}$ and $\mathrm{C}_{2} \mathrm{~B}_{n}$ are mainly dictated by the bonding capabilities of the boron. It is worth noting that the predicted lowest-energy structure $\mathrm{CB}_{7}{ }^{-}$ $\left(\mathbf{M 4}^{-}\right)$is consistent with that from a recent experimental study. ${ }^{33}$

With the increase of carbon composition in the mixed carbon-boron cluster, the lowest-energy structures of $\mathrm{C}_{3} \mathrm{~B}_{n}$ and $\mathrm{C}_{4} \mathrm{~B}_{n}(n=4-8)$ become less compact. Some floppy ring structures are observed, such as those of M11 ${ }^{-}\left(\mathrm{C}_{3} \mathrm{~B}_{4}^{-}\right), \mathbf{M 1 2}^{-}$ $\left(\mathrm{C}_{3} \mathrm{~B}_{5}^{-}\right)$, M13 $\left(\mathrm{C}_{3} \mathrm{~B}_{6}\right)$, M16 $\left(\mathrm{C}_{4} \mathrm{~B}_{4}\right)$, M16 ${ }^{-}\left(\mathrm{C}_{4} \mathrm{~B}_{4}^{-}\right)$, M17 $\left(\mathrm{C}_{4} \mathrm{~B}_{5}\right)$, and M16 ${ }^{-}\left(\mathrm{C}_{4} \mathrm{~B}_{5}^{-}\right)$(cf. Table 1). Another obvious structural perturbation due to the increase of carbon composition is that the coordination number of the central B atom is notably reduced. For example, the maximum coordination number of the central B atom is reduced to six in M12, M14, and M14 ${ }^{-}$ and five in M18, and M20, and even many tetracoordinate boron atoms show up in the $\mathrm{C}_{4} \mathrm{~B}_{n}(n=4-8)$ series.
3.3. Molecular Wheels $\mathrm{CB}_{7}, \mathrm{CB}_{7}^{-}, \mathrm{CB}_{8}, \mathrm{C}_{2} \mathrm{~B}_{6}$ and Derivatives of Planar Tetra-, Penta-, and Hexacoordinate Boron Motifs. The global minima $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) and the anion $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4}^{-}\right)$are molecular wheel-like, where the central B atom is hepta- or octacoordinated, one less or equal to the maximum coordination number of the central B atom (octacoordinated ${ }^{49}$ ) in the planar molecular wheel boron clusters. The hetero C atom occupies peripheral position in $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), and anion $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4} 4^{-}\right)$. No B-centered molecular-wheel-like structures are found when the number of the peripheral C atom exceeds two.
These molecular-wheel-like structures $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), and $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4}^{-}\right)$possess relatively high stabilities. For the close-shell species $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), and $\mathrm{CB}_{7}{ }^{-}$ (M4 ${ }^{-}$), the energy differences $\left(\Delta E_{\text {S-T }}\right)$ between the singlet and the lowest triplet states are $16.75,43.80$, and $38.96 \mathrm{kcal} / \mathrm{mol}$ [calculated at the $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{g}(\mathrm{d})$ level], respectively. The $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), and $\mathrm{CB}_{7}{ }^{-}\left(\mathbf{M 4}^{-}\right)$are much more stable

[^7]Scheme 1. Schematic Illustrations of (a) Matrix Structure of Hepta- and Octacoordinate Boron Wheels: $\mathrm{B}_{7} \mathrm{C}$ (M4), $\mathrm{B}_{8} \mathrm{C}$ (M5), and $\mathrm{B}_{6} \mathrm{C}_{2}$ (M8) and Anion $\mathrm{B}_{7} \mathrm{C}\left(\mathbf{M 4}^{-}\right)$; (b) the Derivatives of Tetracoordinate Boron Structural Motifs: - $\mathrm{B}\left(\mathrm{B}_{3} \mathrm{C}\right.$ ) - (in M2), $-\mathrm{B}\left(\mathrm{B}_{2} \mathrm{C}_{2}\right)-$ (in M18 ${ }^{-}$, M19, and M19 ${ }^{-}$), $-\mathrm{B}\left(\mathrm{B}_{2} \mathrm{C}_{2}\right)^{\prime}-$ (in $\mathbf{M 1 5} 5^{-}$), $-\mathrm{B}\left(\mathrm{B}_{4}\right)$ - (in $\mathbf{M 3}^{-}$), $-\mathrm{B}\left(\mathrm{B}_{2} \mathrm{C}_{2}\right)^{\prime \prime \prime}-$ (in M11), and $-\mathrm{B}\left(\mathrm{B}_{2} \mathrm{C}_{2}\right)^{\prime \prime \prime \prime}-$ (in M20 $\mathbf{O}^{-}$); (c) the Derivatives of Pentacoordinate Boron Structural Motifs: $-B\left(B_{4} C\right)-$ (in M5 ${ }^{-}$and $\mathbf{M 9}^{-}$), $-B\left(B_{3} C_{2}\right)-($ in $M 9),-B\left(B_{4} C\right)^{\prime}-($ in $M 15),-B\left(B_{3} C_{2}\right)^{\prime}-($ in $M 15),-B\left(B_{2} C_{3}\right)-($ in $M 18)$, and $-\mathrm{B}\left(\mathrm{B}_{3} \mathrm{C}_{2}\right)^{\prime \prime}-$ (in M20); (d) the Derivatives of Hexacoordinate Boron Structural Motifs: $-\mathrm{B}\left(\mathrm{B}_{4} \mathrm{C}_{2}\right)-\left(\right.$ in $\left.\mathrm{M8}^{-}\right)$, $-\mathrm{B}\left(\mathrm{B}_{5} \mathrm{C}\right)-($ in M 10$)$, $-B\left(B_{5} C\right)^{\prime}-\left(\right.$ in $\left.\mathbf{M 1 0}^{-}\right)$, and $-B\left(B_{3} C_{3}\right)-($ in M12 $)$

compared to the second-lowest-energy structures by 27.09 , 16.75 , and $35.58 \mathrm{kcal} / \mathrm{mol}$, respectively [calculated at the CCSD$(\mathrm{T}) / 6-311+\mathrm{g}(\mathrm{d})$ level]. For the $\mathrm{C}_{2} \mathrm{~B}_{6}$, the second-lowest-energy structure M8-iso is nearly isoenergetic to the M8, which is also molecular wheel-like (cf. Table 1). The energy difference between M8 and the third-lowest-energy structure of $\mathrm{C}_{2} \mathrm{~B}_{6}$ is $15.51 \mathrm{kcal} / \mathrm{mol}$ (see the Supporting Information).

A main structural feature of the mixed carbon-boron clusters $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ and their anions is that the planar multicoordinate (tetra-, penta-, and hexacoordinate) boron is a prevalent structural motif. Scheme 1 summarizes various planar multicoordinate boron structural motifs seen in M1-M20 and M1 ${ }^{-}$$\mathbf{M 2 0}{ }^{-}$. Indeed, the molecular wheel-like structures $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), and $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4}^{-}\right)$may be viewed as a parent structure from which various planar tetra- (Scheme 1b), penta- (Scheme 1c), and hexacoordinate (Scheme 1d) boron can be derived. Apparent examples include the neutral molecular
wheels $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), and their anions $\mathrm{CB}_{8}{ }^{-}\left(\mathbf{M 5}^{-}\right)$ and $\mathrm{C}_{2} \mathrm{~B}_{6}{ }^{-}\left(\mathbf{M 8}^{-}\right)$. The attachment of one extra electron to the $\mathrm{CB}_{8}$ (M5) or $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) leads to the reduction of the coordination number of the central B atom from the compact octa- or heptacoordination to the penta- or hexacoordination, respectively. For $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), and $\mathrm{CB}_{7}{ }^{-}$ (M4 ${ }^{-}$), the Wiberg bond indices (WBI) of the central B atom are analyzed by using the NBO program ${ }^{51}$ and are listed in Table 3. Although the coordination number of B atoms may increase up to eight, the WBI value of the central B atom is always less than four, suggesting that the octet rule is not violated. The bonds between the central B atom and the surrounding B and $C$ atoms, $B_{\text {center }}-B$ and $B_{\text {center }}-C$, are electron-deficient multicenter bonds.

[^8]Table 3. Calculated Properties of Molecular Wheel-Like Clusters $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{7}^{-}{ }^{(M 4-}$ ), $\mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), the Wiberg Bond Indices for the Central B Atom, and NICS Values (ppm) above the Mass Center of Cluster (B3LYP/6-311+G(d,p) Level of Theory)

To gain more insights into the bonding nature of the planar multicoordinate boron structures, the molecular orbitials (MOs) of $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) are further analyzed. An in-depth discussion of MOs of $\mathrm{CB}_{7}{ }^{-}\left(\mathbf{M 4}^{-}\right)$has been given in ref 33. The neutral $\mathrm{CB}_{7}$ (M4) possesses consistent electronic configurations and very similar shapes of MOs as those of $\mathrm{CB}_{7}^{-}$ ( $\mathbf{M 4}^{-}$). The removal of one electron from the $\mathrm{CB}_{7}{ }^{-}$results in little structural change (Scheme 1a). The electronic configurations and plots of MOs of the $\mathrm{CB}_{7}(\mathbf{M 4}), \mathrm{CB}_{7}^{-}\left(\mathbf{M 4}^{-}\right), \mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) are shown in Figure 2. A common feature of MOs in $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4} 4^{-}\right), \mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) is that both the $\sigma$ and $\pi$ electrons are highly delocalized above the molecular plane, which is responsible for relatively high stabilities of these species. All molecular-wheel-like structures are $\pi$-aromatic with three $\pi$-orbitals [HOMO, $1 \mathrm{~b}_{1}, \mathrm{HOMO}-1$, $1 \mathrm{a}_{2}$, and HOMO-5, $1 \mathrm{~b}_{1}$ in $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8); HOMO, $1 \mathrm{a}_{2}$, HOMO$1,2 \mathrm{~b}_{1}$, and HOMO-6, $1 \mathrm{~b}_{1}$ in $\mathrm{CB}_{7}$ (M4) and $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4}{ }^{-}\right)$; HOMO, 1a $\mathrm{a}_{2}$, HOMO-1, 2 $\mathrm{b}_{1}$, and HOMO-5, $1 \mathrm{~b}_{1}$ in CB C $_{8}$ (M5)]. The $\pi$ MOs of $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4} 4^{-}\right), \mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) are very similar in shape, composed mainly of the 2 p orbitals of the perimeter boron atoms. The $\mathrm{CB}_{7}^{-}\left(\mathbf{M 4}^{-}\right), \mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) all have six $\pi$-electrons, satisfying the $(4 n+2)$ Hückel rule. The $\mathrm{CB}_{7}(\mathbf{M 4})$ has its highest $\pi$ MO (HOMO, 1a 2 ) half-filled, resulting in a $(4 n+1) \pi$-electron system. It has been proposed that the $\mathrm{CB}_{7}^{-}\left(\mathbf{M} 4^{-}\right)$has doubly aromatic characters, namely, both $\pi$-aromatic and $\sigma$-aromatic. ${ }^{33}$ We expect that the molecular wheel-like clusters $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) are also doubly aromatic, similar to $\left.\mathrm{CB}_{7}^{-}(\mathbf{M 4})^{-}\right)$even though the $\sigma$ aromaricity is less pronounced. The three highly delocalized $\sigma$ orbitals [HOMO-2, $6 \mathrm{a}_{1}$, HOMO - $3,4 \mathrm{~b}_{2}$, and HOMO-6, $4 \mathrm{a}_{1}$ in $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8); HOMO-2, $4 \mathrm{~b}_{2}$, HOMO-3, $6 \mathrm{a}_{1}$, and HOMO-7, $4 \mathrm{a}_{1}$ in CB $_{7}$ (M4); HOMO2, 5b $\mathrm{b}_{2}$, $\mathrm{HOMO}-3,6 \mathrm{a}_{1}$, and HOMO-7, $4 \mathrm{a}_{1}$ in CB 8 (M5)] are responsible for the bonding between the central B atom and the perimeter atoms, which is considered to confer the $\sigma$ aromaticity for the molecular wheel-like clusters. ${ }^{33}$ The aromaticities of $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{7}^{-}$(M4 ${ }^{-}$), $\mathrm{CB}_{8}$ (M5), and $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8) can be further evaluated via calculating the NICS values ${ }^{52}$ above the center of the cluster plane. The absolute NICS values (cf. Table 3) of these molecular wheel-like clusters are quite high [compared to that of the benzene whose NICS $=-8.0$ at the B3LYP/6-311+G(d,p) level]. The slightly smaller (absolute) NICS value of $\mathrm{CB}_{7}$ (M4), compared to $\mathrm{CB}_{7}^{-}$(M5), may be rationalized by its inherent $(4 n+1) \pi$-electrons.

Taking $\mathrm{CB}_{8}{ }^{-}\left(\mathbf{M 5}^{-}\right)$as an example, we further analyzed its bonding characteristic in the reduced planar pentacoordinate

[^9]boron system. The MOs of $\mathrm{CB}_{8}^{-}\left(\mathbf{M 5}^{-}\right)$in Figure 2c are compared with those of $\mathrm{CB}_{8}$ (M5) in Figure 2d. $\mathrm{CB}_{8}{ }^{-}\left(\mathbf{M 5}{ }^{-}\right)$ is also a planar structure with the central B atom having reduced pentacoordination. Although the structure of $\mathrm{CB}_{8}{ }^{-}$is not as compact as $\mathrm{CB}_{8}$, the shapes of $\pi \mathrm{MOs}$ (HOMO-1, $2 \mathrm{a}^{\prime \prime}$; HOMO-2, 12 $\mathrm{a}^{\prime}$; and HOMO-7, $1 \mathrm{a}^{\prime \prime}$ ) of $\mathrm{CB}_{8}{ }^{-}$are very similar to those of $\mathrm{CB}_{8}$ (Figure 2c). However, the highly delocalized $\sigma$ orbitals are no longer seen in $\mathrm{CB}_{8}{ }^{-}$due to change of the coordination environment. The negative NICS value (cf. Table 3 ) above the molecular plane of $\mathrm{CB}_{8}{ }^{-}$confirms its $\pi$ aromaticity. The slightly smaller NICS value of $\mathrm{CB}_{8}{ }^{-}$(compared to that of $\mathrm{CB}_{8}$ ) probably originates from less contribution of $\sigma$ aromaticity, because of strongly fragmental $\sigma$ orbitals (HOMO-3, 11a', HOMO-4, 10a', and HOMO-8, 7a' in Figure 2d).

We now draw some preliminary conclusions on the bonding and structural evolution of small-sized mixed carbon-boron clusters: (1) The planar multicoordinate (with tetra-, penta-, and hexacoordination) boron is the dominant structural unit in $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$, which can be viewed as derivatives of the molecular wheel-like clusters $\mathrm{CB}_{7}$ (M4), $\mathrm{CB}_{8}$ (M5), $\mathrm{C}_{2} \mathrm{~B}_{6}$ (M8), and $\mathrm{CB}_{7}^{-}\left(\mathbf{M} 4^{-}\right)$; (2) the central B atom forms multicenter electron-deficient bonds with the perimeter atoms to stablize the multicoordinate structures; (3) the 2 p orbital of the peripheral boron atoms participates in the formation of the $\pi$ molecular orbitals which are highly delocalized on the molecular plane and significantly enhance the stability of the clusters.
3.4. Planar Multicoordinate (Tetra-, Penta-, and Hexacoordinate) Carbons. It has been found that the B atom can assist the C atom to achieve unusual hypercoordination structure. ${ }^{53}$ For example, the spatial penta- and hexacoordinate C atom has been observed in the carborane molecules via the formation of electron-deficient B-C bonds. ${ }^{53}$ Schleyer and coworkers ${ }^{29-31}$ were the first to put forth the idea of using B atoms as constituent parts to stabilize hypercoordinate C atom in a planar structure. A variety of planar penta- and hexacoordinate carbon compounds have been theoretically studied by Schleyer and co-workers. ${ }^{29-31,54}$ Most of the reported planar penta- and hexacoordinate carbon compounds are built upon prototype carbon-boron clusters, such as the $\mathrm{CB}_{6}{ }^{2-}$ and $\mathrm{CB}_{8} .{ }^{29-31,54}$ In this study, besides the global minima shown in Table 1, we also obtained a large number of local minima through sampling the potential energy surface for each of $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ clusters. Notably, many local minima contain the planar tetra- (Table 4, T1-T12), penta- (Table 5, P1-P9), and hexacoordinate (Table 6, H1-H6) carbon units although they are metastable structures.

Planar Tetracoordinate Carbon (ptC). Table 4 collects various ptC structural motifs ( $\mathbf{T 1} \mathbf{- T 1 2}$ ) and their corresponding metastable minima structures. We can classify the observed ptC structural motifs into three types: (I) $\mathbf{T 1} \mathbf{- T 6}$, the ptC center is surrounded by four atoms on one side; (II) T7-T10, the ptC center is stabilized by three and one atoms on each side; (III) T11-T12, the ptC center is stabilized by two atoms on each side. For ptC motifs $\mathbf{T 1}, \mathbf{T} 7$, and $\mathbf{T 1 1}$, the surrounding atoms are all boron. The other motifs, such as T2-T6 (type I), T8T10 (type II), and T12 (type III), can be viewed as derivatives of T1, T7, and T11, respectively, with one or two surrounding B atoms replaced by C atoms. This mechanism is somewhat

[^12]and anion clusters are studied here, it is possible to obtain more pmC structural motifs if the cation, dication, and dianion etc. are included, e.g., the $-\mathrm{CB}_{6}{ }^{2-}-.{ }^{31}$

### 3.5. Stability Issues of the Planar Multicoordinate Carbon.

 Although the results of various ptC , ppC , and phC local minimum structures are interesting, all these structures have relatively high energies, and most of them are $20 \mathrm{kcal} / \mathrm{mol}$ or 1.0 eV higher in energy than the predicted lowest-energy isomers[^13]Table 7. Extrapolated ptC and ppC Structural Motifs and Their Hydrides

| Structural |
| :---: |

| PtC | | Hydrides of |
| :---: |
| ptC Motifs | | Structural <br> Motifs of <br> ppC |
| :---: | | Hydrides of |
| :---: |
| ppC Motifs |

${ }^{a}$ The structures are optimized and frequencies are calculated at the B3LYP/6-311+G(d,p) level of theory.
(cf. Tables 4-6). In particular, the ppC - and phC -containing carbon-boron clusters (cf. Tables 5 and 6) all have relatively high energies. The high-energy characteristic of these clusters may be understood from different bonding behavior of C and $B$ atoms even though boron and carbon are neighbor elements in the second row of the periodic table with similar valence electron structures $2 s^{2} 2 p^{1}$ and $2 s^{2} 2 p^{2}$. The formation of two-center/two-electron bond ( $2 \mathrm{c} / 2 \mathrm{e}$ bond) is more favorable for C atom. In contrast, B atom tends to form electron-deficient bonds (such as the $3 \mathrm{c} / 2 \mathrm{e}$ bond) which can lead to versatile tetra-, penta-, hexa, hepta-, and even octacoordination boron. ${ }^{49,55}$ Hence, C atoms tend to occupy peripheral positions in the lowlying isomers of the carbon-boron clusters (cf. Table 1 and Supporting Information).

Can these ptC, ppC, and phC-containing (Tables 4-6) metastable structures be synthesized in the laboratory? This is still an open question. A necessary condition for realizing these novel structures in the laboratory is that intrinsically high rearrangement barriers exist for the pmC to prevent structural isomerization. For example, it has been shown that $\sim 1.0 \mathrm{eV}$ barrier height exists for the rearrangement of the $\mathrm{C}_{3} \mathrm{~B}_{4}$ toward its lowest-energy isomer. ${ }^{29}$ Some $a b$ inito molecular dynamics simulations also confirm kinetic stabilities of some phC compounds. ${ }^{31}$ In any case, the energy data in Tables $4-6$, as well as a recent photoelectron spectroscopy experiment, ${ }^{33}$ suggest that direct synthesis of $\mathrm{ptC}, \mathrm{ppC}$, and phC -containing carbon-boron compounds will be very challenging.

Figure 3. Relative stabilities of (a) ptC-containing hyparenes [ $\left.\mathbf{T 4}-(\mathrm{CH})_{6}\right]$, hydrides and their boron-centered isomers; (b) ppC-containing hyparenes [P1$\left.(\mathrm{CH})_{3}\right]$, hydrides and their boron-centered isomers; (c) ppC-containing hyparenes [ $\left.\mathbf{P 2}-(\mathrm{CH})_{2}\right]$, hydrides and their boron-centered isomers. The relative energies of hydrides are given in the parentheses. All relative energies are in units of $\mathrm{kcal} / \mathrm{mol}$.
3.6. Relative Stabilities of ppC-Containing Hyparenes Molecules. As mentioned previously, it is possible to significantly enhance the stabilities of ptC and ppC species by making an extended molecular system, for example, by combining the ptC and ppC units with appreciable hydrocarbon units $-(\mathrm{CH})_{n}-$. An important feature of the $\mathrm{ptC}, \mathrm{ppC}$, and phC structural motifs is that they are extendable. Indeed, a family of ppC-containing hyparenes molecules have been theoretically proposed based on the structural units of $-\mathrm{CB}_{5}-(\mathbf{P} 1),-\mathrm{C}_{2} \mathrm{~B}_{4}-(\mathbf{P} 2)$, and $-\mathrm{C}_{3} \mathrm{~B}_{3}-(\mathbf{P 8}) .{ }^{30}$ Moreover, myriad phC-containing molecules were also recently rationalized based on the building block $-\mathrm{CB}_{6}{ }^{2-}-{ }^{31}$

The pyramidal conversion has been shown to be a major isomerization mechanism in the boron-containing ptC system. ${ }^{56}$ However, few studies have examined relative stabilities between carbon-centered and boron-centered isomers in the extended pmC systems. ${ }^{31}$ It has been shown that the exchange of the central C atom with a perimeter B atom in the phC systems can significantly lower the system energy, ${ }^{31}$ consistent with the stability tendency in the mixed carbon-boron cluster. Here, using three hypothetical monocylic hyparene molecules, (T4$(\mathrm{CH})_{6}, \mathbf{P} 1-(\mathrm{CH})_{3},{ }^{30}$ and $\left.\mathbf{P} 2-(\mathrm{CH})_{2}{ }^{30}\right)$, we confirm that it is possible to reduce the energy difference or even reverse the relative stabilities of the boron-centered and carbon-centered isomers by combining the ptC and ppC motifs with the hydrocarbon units $-(\mathrm{CH})_{n}-$. We can obtain hydrides by saturating the ptC ( $\mathbf{T 4}$ ) and $\mathrm{ppC}(\mathbf{P 1}$ and $\mathbf{P 2}$ ) motifs with two hydrogen atoms, which are all stable local minima in the planar geometry. As expected, the exchange of the central C atom with a perimeter B atom in the hydrides significantly lowers the energy (see Figure 3, energy values in the parentheses).

Conversely, for the hyparene T4-(CH) $6, \mathbf{P 1}-(\mathrm{CH})_{3},{ }^{30}$ and $\mathbf{P 2}$ $(\mathrm{CH})_{2},{ }^{30}$ the trend in the relative stabilities can be very different. In fact, one can see from Figure 3a and $3 b$ that the ptC- and ppC-containing T4-(CH) $)_{6}$ and $\mathbf{P 1}-(\mathrm{CH})_{3}$ are actually more stable than their boron-centered isomers by 6.68 and $4.73 \mathrm{kcal} / \mathrm{mol}$, respectively. Also, the largest energy difference between the boron-centered isomer and the ppC isomer of the $\mathbf{P} 2-\mathrm{C}_{2} \mathrm{H}_{2}$ (Figure 3c) decreases to $\sim 5 \mathrm{kcal} / \mathrm{mol}$. The enhanced stabilities of these ptC- and ppC-containing hyparenes $\mathbf{T 4}-(\mathrm{CH})_{6}, \mathbf{P 1}$ $(\mathrm{CH})_{3}$, and $\mathbf{P} 2-(\mathrm{CH})_{2}$ are mainly due to their rigid coplanar structure. The replacement of the central C atom by B atom in T4-(CH) $)_{6}, \mathbf{P} 1-(\mathrm{CH})_{3}$, and $\mathbf{P 2}-(\mathrm{CH})_{2}$ destroys the planarity of the system as shown in Figure 3. The B atom is pushed out of the molecular plane, which reduces relative stabilities the boroncentered isomers. Note that the phC would benefit less in relative stabilities from the formation of the hyparenes molecule $\mathrm{CB}_{6}$ $(\mathrm{CH})_{2},{ }^{31}$ becasue the exchange of the central C atom with the perimeter $B$ atom will result in an energetically more favorable planar hexacoordinate boron center.

Finally, we remark that although the ptC- and ppC-containing hyparenes $\mathbf{T} 4-\mathrm{C}_{6} \mathrm{H}_{6}$ and $\mathbf{P 1}-\mathrm{C}_{3} \mathrm{H}_{3}$ appear to be very stable, they are still local minimum structures. For example, for the P1$(\mathrm{CH})_{3}$, a lower energy $[-13.86 \mathrm{kcal} / \mathrm{mol}$ at the B3LYP/6$311+\mathrm{G}(\mathrm{d}, \mathrm{p})$ level] ppC hyparene structure, $\mathbf{P 1}-(\mathrm{CH})_{3}$-iso, is found, which can be viewed as relocating the position of a $-\mathrm{CH}-$ substituent, as shown in Figure 4a. Still, the exchange of the central C atom with a perimeter B atom in the $\mathrm{P} 1-(\mathrm{CH})_{3^{-}}$ iso raises the total energy, confirming the high stability of this new hyparene structure. However, a planar hexacoordinate boron-centered isomer structure (Figure 4 b ) is found to be more stable than both the ppC-containing hyparenes $\mathbf{P 1}-\mathrm{C}_{3} \mathrm{H}_{3}$ and $\mathbf{P 1}$ -

Figure 4. (a) A ppC-containing hyparene P1-(CH) $)_{3}$-iso and its boron-centered isomers. (b) Low-energy phC-centered isomer. [Values in parentheses represent relative electronic energies calculated at the B3LYP/6-311+G(d,p) level and in units of kcal/mol.] The geometric data of hyparene P1-(CH) ${ }_{3}$-iso and the hexacoordinate boron-centered isomer are given in Supporting Information.
$\mathrm{C}_{3} \mathrm{H}_{3}$-iso by 30.26 and $16.40 \mathrm{kcal} / \mathrm{mol}[\mathrm{B} 3 \mathrm{LYP} / 6-311+\mathrm{G}(\mathrm{d}, \mathrm{p})$ level], respectively. Despite the fact that the hyparenes (such as $\mathbf{P} 1-\mathrm{C}_{3} \mathrm{H}_{3}$ and $\mathbf{P} 1-\mathrm{C}_{3} \mathrm{H}_{3}$-iso) are not necessarily the global minima, their unique rigid coplanar structure coupled with energetically favorable ppC motif provide a better hope for experimental isolation in the laboratory. It may be worthy of comparing the hyparene structures with other known constrained organic systems, such as fenestranes. ${ }^{4 \mathrm{~d}, 22}$ The latter systems are capable of possessing both relative high energies (because of the constraints) and structural rigidity. ${ }^{4 d, 22}$

## 4. Conclusions

We report the first comprehensive study of the planar tetra-, penta-, and hexacoordinate carbons covering all the small-sized carbon-boron clusters $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ and their anions. A new boron-stabilized ptC molecule, $\mathrm{CB}_{4}$, is identified, which is stable enough for experimental synthesis. Besides the $\mathrm{CB}_{4}$, more than 30 forms of myriad $\mathrm{ptC}, \mathrm{ppC}$, and phC structural motifs are found. Although these are metastable structures, they enrich knowledge of bonding styles for the carbon atoms. We also showed that most $\mathrm{ptC}-, \mathrm{ppC}$-, and phC -containing carbon-boron clusters are energetically high-lying isomers. The more favorable structures are the planar tetra-, penta-, and hexacoordinate borons, which are the dominant structural units in the low-lying isomers of $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ and their anions. The exchange of the
planar-multicoordinate central C atom with the perimeter B atom in the $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ clusters generally results in isomers with much lower energies. This may explain why pmC clusters are hardly detectable in a recent photoelectron spectroscopy experiment. On the other hand, it is possible to significantly improve the stabilities of the ptC and ppC units by attaching them with appreciable hydrocarbon units, such as the $-(\mathrm{CH})_{n}-$ (forming the rigid hyparene structures). ${ }^{30}$ Even though the hyparenene structures are still not the global minima, the molecular design offers a synthetic route to realize pmC-containing compounds.

Acknowledgment. We thank Dr. Satya Bulusu and Dr. Yi Gao for valuable discussions. This work was supported by grants from NSF (CHE-0427746 and CHE-0701540), DOE (DE-FG02 04ER46164), and the Nebraska Research Initiative, and by the Research Computing Facility at University of Nebraska-Lincoln.

Supporting Information Available: The complete reference 42, the geometries and relative energies of the top three lowlying isomer structures of carbon-boron clusters $\mathrm{C}_{m=1-4} \mathrm{~B}_{n=4-8}$ and their anions, the geometrical data for structures given in Figure 4, and the infrared spectrum of the global minimum $\mathrm{CB}_{4}$. [^10]:    ${ }^{a}$ The relative stabilities of ptC clusters are evaluated via their energy difference (value in parentheses, calculated at $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(\mathrm{d}, \mathrm{p})$ level of theory) with respect to the lowest-energy isomer listed in Table 1.
    the ptC shown above, the structural motif $\mathbf{P 1}$ can be considered as a matrix structure for all other motifs $\mathbf{P 2}-\mathbf{P} 9$ with one or more perimeter B atoms replaced by C atoms. In addition, a local minimum structure containing two ppC motifs is also found (see the No. 3 prototype structure based on the motif $\mathbf{P} 2$ in Table 5). This suggests that it is conceivable to build more complex structures containing more than one pmC units.

    Planar Hexacoordinate Carbon (phC). Besides the ptC and ppC , some phC units are also revealed. Table 6 presents six types of phC structural motifs, H1-H6. Besides the known phC structures $\left(\mathrm{C}_{3} \mathrm{~B}_{4}, \mathbf{H} 4-\mathbf{H 6}\right),{ }^{30}$ the neutral $\mathrm{C}_{2} \mathrm{~B}_{5}(\mathbf{H} 3)$ and anions
    $\mathrm{C}_{2} \mathrm{~B}_{5}^{-}\left(\mathbf{H 3}^{-}\right), \mathrm{C}_{3} \mathrm{~B}_{4}^{-}\left(\mathbf{H 6}^{-}\right)$are also phC-containing local minimum structures. Also, two new isomeric structural motifs $-\mathrm{C}_{3} \mathrm{~B}_{4}-(\mathbf{H} 1$ and $\mathbf{H 2})$ are found in the $\mathrm{C}_{3} \mathrm{~B}_{5}$ clusters.

    Based on the ptC, ppC, and phC structural motifs listed in Tables $4-6$, a simple rule may be outlined to understand the evolution of boron-stabilized planar multicoordinate carbon. From Tables 4-6, the structural motifs $\mathbf{T 2}-\mathbf{T} 6$ and $\mathbf{P 2 - P 9}$ can be viewed as derivatives of $-\mathrm{CB}_{4}-(\mathbf{T 1})$ and $-\mathrm{CB}_{5}-(\mathbf{P} 1)$, respectively, with one or two surrounding boron atoms being replaced by the carbon atoms. The phC structural motifs H1H6 can actually be viewed as derivatives of the phC compound

[^11]:    ${ }^{a}$ The relative stabilities of ppC clusters are evaluated via their energy difference (value in parentheses, calculated at $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(\mathrm{d}, \mathrm{p})$ level of theory) with respect to the lowest-energy isomer listed in Table 1.
    $\mathrm{CB}_{6}{ }^{2-} .{ }^{30}$ According to this evolution rule, we are able to extrapolate more planar multicoordinate carbon motifs. Table 7 lists extrapolated ptC and ppC structural motifs, T13-T16
    and P10, which are not observed during sampling of the potential energy surface, yet they can stably exist in the hypothetical carbon-boron hydrides. ${ }^{4 h, 56,57}$ Since only neutral

[^12]:    ${ }^{a}$ The relative stabilities of phC clusters are evaluated via their energy difference (value in parentheses, calculated at $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(\mathrm{d}, \mathrm{p})$ level of theory) with respect to the lowest-energy isomer listed in Table 1.
