# Planar, Twisted, and Trans-Bent: Conformational Flexibility of Neutral Diborenes 

Yuzhong Wang, Brandon Quillian, Pingrong Wei, Yaoming Xie, Chaitanya S. Wannere, R. Bruce King, Henry F. Schaefer, III, Paul v. R. Schleyer,* and Gregory H. Robinson*<br>Department of Chemistry and the Center for Computational Chemistry, The University of Georgia, Athens, Georgia 30602-2556

Received January 11, 2008; E-mail: robinson@chem.uga.edu

Realization of the fascinating potential of boron homonuclear multiple bond chemistry has long frustrated chemists. ${ }^{1-3}$ Boronboron double bonds are represented by two olefin-like classes of compounds: (1) the isoelectronic diboron dianions, $\left[\mathrm{R}_{2} \mathrm{BBR}_{2}\right]^{2-}$, and (2) the Lewis base-stabilized neutral diborene complexes, $\mathrm{L}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{L}(\mathrm{L}=$ Lewis base $)$. Although diboron dianions and their alkali metal salts were proposed as promising $\mathrm{B}=\mathrm{B}$ double bond candidates two decades ago, ${ }^{4}$ corroborating synthetic and structural evidence has been rare. ${ }^{5-7}$ In contrast, neutral Lewis basestabilized diborenes are attractive alternatives. While the highly reactive parent neutral diborene(2), $\mathrm{HB}=\mathrm{BH},{ }^{8}$ has only been characterized in matrices, ${ }^{9}$ complexation with appropriate Lewis base ligands is a promising approach to viable $L(H) B=B(H) L$ derivatives. Although the theoretical development of BCO chemistry ${ }^{10-14}$ included the computational prediction of the car-bonyl-stabilized diborene, $\mathrm{OC}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{CO},{ }^{12}$ such complexes have not been experimentally realized. In this regard, bulky N -heterocyclic carbene (NHC) ligands are attractive due to their strong electron-donating properties coupled with their ability to provide effective protection to the $\mathrm{HB}=\mathrm{BH}$ core. ${ }^{15,16}$

Our recent potassium graphite reduction of $\mathrm{RBBr}_{3}(\mathrm{R}=$ : $\mathrm{C}\left\{\mathrm{N}\left(2,6-\operatorname{Pr}^{i}{ }_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right) \mathrm{CH}\right\}_{2}$ ) afforded $\mathrm{R}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{R}$, 1, the first structurally characterized neutral diborene as well as a diborane complex, $\mathrm{R}(\mathrm{H})_{2} \mathrm{~B}-\mathrm{B}(\mathrm{H})_{2} \mathrm{R}, 2 .{ }^{17} \mathrm{We}$ now utilize a less bulky NHC ligand ( $\mathrm{R}^{\prime}=: \mathrm{C}\left\{\mathrm{N}\left(2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2}\right) \mathrm{CH}\right\}_{2}$ ) to prepare the second neutral diborene, $R^{\prime}(H) B=B(H) R^{\prime}, \mathbf{3}$, as well as the corresponding $\mathrm{R}^{\prime}(\mathrm{H})_{2} \mathrm{~B}-\mathrm{B}(\mathrm{H})_{2} \mathrm{R}^{\prime}$ diborane, 4. In contrast to planar diborene $\mathbf{1}$, the new diborene, $\mathbf{3}$, exhibits remarkable conformational variations in the solid state. X-ray determinations of three different crystals reveal not only planar (3a) but also twisted (3b) and trans-bent (3c) molecular structures! Herein we report these results and the computational examination of $\mathbf{3}$ and $4 .{ }^{18,19}$

3a

Twisted
3b

Trans-bent 3c

While trans-bent geometries of the heavier group 13 dianionic alkene analogues, $\left[\mathrm{H}_{2} \mathrm{E}=\mathrm{EH}_{2}\right]^{2-}(\mathrm{E}=\mathrm{Al}, \mathrm{Ga}$, In$)$, are predicted to be favored over planar alternatives, ${ }^{20}$ both diboron dianions ( $\mathrm{E}=$ B) ${ }^{4-7}$ and the Lewis base-stabilized neutral diborenes ( $\mathbf{1}$ and $\mathrm{OC}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{CO})^{12,17}$ prefer planar geometries. Hence, the twisted (3b) and trans-bent (3c) structures of $\mathbf{3}$ are unexpected. The pyramidal tricoordinate boron atoms in 3c contrast with the predominant trigonal planar geometries. Indeed, pyramidal boron environments have only been reported in cyclic systems. ${ }^{21}$

Our earlier study showed that the $\mathrm{RBBr}_{3}: \mathrm{KC}_{8}$ ratio affects the diborene yield. ${ }^{17}$ The reaction of $\mathrm{R}^{\prime} \mathrm{BBr}_{3}$ with $\mathrm{KC}_{8}$ in a $1: 5$ ratio in
$\mathrm{Et}_{2} \mathrm{O}$ resulted in isolation of red-colored 3 ( $15.8 \%$ ), together with colorless $4, \mathrm{R}^{\prime}(\mathrm{H})_{2} \mathrm{~B}-\mathrm{B}(\mathrm{H})_{2} \mathrm{R}^{\prime}$. Reduction using a $\mathrm{R}^{\prime} \mathrm{BBr}_{3}: \mathrm{KC}_{8}$ ratio of $1: 6.2$ only resulted in $\mathbf{4}$. Similar to the formation of $\mathbf{1}$ and $\mathbf{2},{ }^{17}$ the preparation of $\mathbf{3}$ and $\mathbf{4}$ involves the well-documented hydrogen abstraction from ethereal solvents in the presence of alkali metals. Both 3a, as black red crystals, and 3b, as ruby-colored crystals, were isolated from the $1: 5 \mathrm{Et}_{2} \mathrm{O} /$ hexane solvent mixture, while 3 c was crystallized from the parent $\mathrm{Et}_{2} \mathrm{O}$ solution. Despite their three different conformations in the solid state, $\mathbf{3 a}-\mathbf{c}$, exhibit identical ${ }^{1} \mathrm{H}$ and ${ }^{11} \mathrm{~B}$ NMR spectra in $\mathrm{C}_{6} \mathrm{D}_{6}$ solution. Furthermore, the broad singlet ${ }^{11} \mathrm{~B}$ NMR resonance of $3\left(+23.45, w_{1 / 2}=587 \mathrm{~Hz}\right)$ corresponds to that of diborene $1\left(+25.30, w_{1 / 2}=946 \mathrm{~Hz}\right)$. The ${ }^{1} \mathrm{H}$ NMR imidazole resonances of $\mathbf{3}$ and $\mathbf{4}$ are 5.96 and 5.91, respectively. There is no evidence for different isomers or states of $\mathbf{3}$ in solution. We conclude that $\mathbf{3 a}-\mathbf{c}$ are polymorphs-the same compound crystallizing in different forms. ${ }^{22}$ The space groups for 3a-c are $P 2_{1} / \mathrm{c}, P-1$, and $P 2_{1} / \mathrm{c}$, respectively, and their packing patterns are completely different. ${ }^{18}$

The ${ }^{11} \mathrm{~B}$ signal of $\mathbf{4}(-31.20)$ is a triplet $\left(J_{\mathrm{BH}}=83.38 \mathrm{~Hz}\right)$ like that of diborane $2(-31.62) .{ }^{17}$ The core of $\mathbf{4}$ consists of two tetrahedral $\mathrm{C}(\mathrm{H})_{2} \mathrm{~B}$ units connected by a boron-boron single bond (1.795(5) $\AA) .{ }^{18}$ Evidently due to the smaller steric repulsion between the carbene ligands, the $\mathrm{B}-\mathrm{B}$ distance in $\mathbf{4}$ is shorter than that in 2 (1.828(4) A).

The trans-bent $\mathrm{C}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{C}$ boron-boron double bond is the most remarkable structural feature of $\mathbf{3 c}$ (Figure 1). Its trans-bending angle, $\theta=36^{\circ}$, is the same as that in the heavier Group 14 ethylene congener, $[\mathrm{R}(\mathrm{Mes}) \mathrm{Ge}=\mathrm{Ge}(\mathrm{Mes}) \mathrm{R}]\left(\mathrm{R}=2,6-\operatorname{Pr}_{2}{ }_{2} \mathrm{C}_{6} \mathrm{H}_{3}\right) .{ }^{23}$ The central $\mathrm{B}=\mathrm{B}$ bond distance in $\mathbf{3 c}(1.679(9) \AA)$ is $0.116 \AA$ shorter

3b

3c

Figure 1. Molecular structures of $\mathbf{3 b}$ and $\mathbf{3 c}$ (thermal ellipsoids represent $30 \%$ probability; hydrogen atoms on carbon are omitted for clarity). Selected bond distances $(\AA)$ and angles (deg): For 3b, B(1)-B(2) 1.582(4), B(1)$\mathrm{C}(1) 1.541(4), \mathrm{B}(2)-\mathrm{C}(22) 1.541(4), \mathrm{B}(1)-\mathrm{H}(1) 1.117(17), \mathrm{B}(2)-\mathrm{H}(2)$ 1.12 (3); $\mathrm{C}(1)-\mathrm{B}(1)-\mathrm{B}(2) 125.0(2), \mathrm{C}(1)-\mathrm{B}(1)-\mathrm{H}(1) 109.9(16)$, $\mathrm{B}(2)-$ $\mathrm{B}(1)-\mathrm{H}(1) \quad 124.9(16), \mathrm{C}(22)-\mathrm{B}(2)-\mathrm{B}(1) \quad 125.1(2), \mathrm{C}(22)-\mathrm{B}(2)-\mathrm{H}(2)$ $107.0(15), B(1)-B(2)-H(2) 127.2(15)$. For $3 \mathbf{c}, \mathrm{~B}(1)-\mathrm{B}(1 \mathrm{~A}) 1.679(9)$, $\mathrm{B}(1)-\mathrm{C}(1) 1.565(5), \mathrm{B}(1)-\mathrm{H}(1) 1.109(18) ; \mathrm{C}(1)-\mathrm{B}(1)-\mathrm{B}(1 \mathrm{~A}) 118.6(5)$, $\mathrm{C}(1)-\mathrm{B}(1)-\mathrm{H}(1) 107.7(19), \mathrm{H}(1)-\mathrm{B}(1)-\mathrm{B}(1 \mathrm{~A}) 118(2)$.

Figure 2. Representation of the frontier orbitals of trans-bent 3c.
than that of the corresponding B-B single bond of 4 (1.795(5) $\AA$ ), but it is about $0.1 \AA$ longer than those in $1(1.560(18) \AA$, av), in dianionic (tetraamino)diborates ${ }^{7}(1.566(9)$ to $1.59(1) \AA$ ), and in $\mathrm{OC}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{CO}\left(1.590 \AA\right.$, computed). ${ }^{12}$ Notably, the $\mathrm{B}=\mathrm{B}$ bond distance of $\mathbf{3 c}$ is only about $0.05 \AA$ longer than in $\left[\mathrm{Mes}_{2} \mathrm{BB}\right.$ $(\mathrm{Mes}) \mathrm{Ph}]^{2-}(1.636(11) \AA)^{5}$ and $\left[\left\{\mathrm{Ph}\left(\mathrm{Me}_{2} \mathrm{~N}\right) \mathrm{BB}\left(\mathrm{NMe}_{2}\right) \mathrm{Ph}\right\}\right]^{2-}(1.627$ A, av). ${ }^{6}$ Each boron atom in $3 \mathbf{c}$ is pyramidal with a $344.3^{\circ}$ bond angle sum. As far as we are aware, $\mathbf{3 c}$ is the first example of pyramidal tricoordinate boron in an acyclic environment. The cyclic silaborirane, $\mathrm{CH}_{2} \mathrm{SiH}_{2} \mathrm{BH},{ }^{24}$ and its analogs have been computed to have pyramidal geometries due to heteroatom-boron p orbital interactions. Constrained systems like 1 -boraadamantane ${ }^{25}$ necessarily have nonplanar boron geometries.

In contrast to the trans-bent structure of $\mathbf{3 c}$, isomer $\mathbf{3 a}$ possesses the same planar $\mathrm{C}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{C}$ core as observed in $1 .{ }^{18}$ Each boron atom in $\mathbf{3 b}$ (Figure 1) also has a planar tricoordinate environment. However, 3b adopts a twisted geometry with a $18.1^{\circ}$ dihedral angle between the two CBH planes. The $\mathrm{B}=\mathrm{B}$ double bond distance of 3b (1.582(4) $\AA$ ) is similar to those of $\mathbf{1}(1.560(18) \AA(\mathrm{av}))$ and 3a (1.602(5) $\AA$ ). Remarkably, the $B=B$ bond distance in the crystal structure of $3 \mathrm{c}(1.679(9) \AA)$ is about $0.1 \AA$ longer. The boronboron double bond character of $\mathbf{3}$ is further supported by the $\pi_{\mathrm{B}=\mathrm{B}}-\pi_{\mathrm{B}}{ }_{\mathrm{B}=\mathrm{B}}$ absorption ( $\lambda_{\text {max }}=574 \mathrm{~nm}$ ).

The B3LYP/6-311+G** DFT optimization of 3c, ${ }^{19}$ starting with the X-ray coordinates, led to a planar geometry and a $\mathrm{B}=\mathrm{B}$ bond distance of $1.605 \AA$, essentially identical with the experimental value (1.602(5) $\AA$ ) of planar 3a. The polymorphism exhibited by $\mathbf{3}$ may be attributed to the combination of a number of factors including (1) the flat potential energy surface; (2) the packing effects in crystals; ${ }^{26,27}(3)$ the polarity of the solvent used for crystallization; and (4) the intramolecular steric repulsion of the carbene ligands. The different packing patterns of $\mathbf{3 a}-\mathbf{c}$ suggest that the associated distinct packing effects may contribute to the stabilization of these polymorphs. ${ }^{18}$ Differences in solvent polarity are known to significantly affect conformational isomerism of molecular ${ }^{28}$ and supramolecular ${ }^{29}$ systems. Indeed, 3a and 3b were isolated from $1: 5 \mathrm{Et}_{2} \mathrm{O} /$ hexane solvent mixtures, whereas $\mathbf{3 c}$ was crystallized from pure $\mathrm{Et}_{2} \mathrm{O}$. Compared to the more sterically demanding ligands in $\mathbf{1}$, the smaller ligands in $\mathbf{3}$ can adjust their orientations more easily to packing forces.

Our numerous computations ${ }^{19}$ employing simplified ligand models $\mathrm{R}^{\prime \prime}(\mathrm{H}) \mathrm{B}=\mathrm{B}(\mathrm{H}) \mathrm{R}^{\prime \prime}\left(\mathrm{R}^{\prime \prime}=: \mathrm{C}(\mathrm{NRCH})_{2}\right.$, with $\mathrm{R}=\mathrm{H}$ or $\left.\mathrm{CH}_{3}\right)$ confirmed the flatness of the potential energy surface. The planar 3a models had $C_{2 h}$ symmetry. The $C_{i}$ models for trans-bent $3 \mathbf{c}$ optimized to the same $C_{2 h}$ geometries. The only minimum (in $C_{2}$ symmetry) corresponding to $\mathbf{3 b}\left(\mathrm{R}=\mathrm{CH}_{3}\right)$ had a small planarization barrier. Consequently, the X-ray coordinates of $\mathbf{3 c}$ were used for the MO model shown in Figure 2. Boron-boron $\pi$-bonding dominates the HOMO, while the HOMO-1 has mixed $\mathrm{B}-\mathrm{B}$ and $\mathrm{B}-\mathrm{H} \sigma$ bonding character (Figure 2). The Wiberg (1.445) and NLMO/NPA (1.515) B-B bond indices, comparable to those
reported for $\mathbf{1}$ (1.408 and 1.656, respectively), support the presence of a $B=B$ double bond in $3 \mathbf{c}$ despite its ca. $0.1 \AA$ boron-boron elongation and trans-bent geometry. The distortion exhibited by 3c does not decrease the boron-boron bond order substantially and supports the dictum "the electronic structure, rather than bond distances, determines the nature of multiple bonds". ${ }^{30}$

The experimental realization of three distinct polymorphic structures of diborene $\mathbf{3}$ may be attributed to a combination of, inter alia, packing effects in the crystal, crystallizing-solvent polarity, and intramolecular ligand steric effects.
