Transition metal catalyzed cycloadditions have proven to be among the most attractive methods to construct medium-sized ring systems. Although [4+4], [6+2], [5+2+1], and [4+2+2] cycloadditions have been elegantly demonstrated to assemble various eight-membered carbocycles, formation of eight-membered nitrogen-containing rings (azocines) has not been explored. In addition, there are no reported examples of successful enantioselective cycloadditions to construct eight-membered rings. We have recently demonstrated that Rh(I) catalysts are capable of effecting enantioselective [2+2+2] cycloadditions with the use of alkenyl heterocumulenes. Herein we describe a highly asymmetric rhodium-catalyzed [4+2+2] cycloaddition of terminal alkynes and dienyl isocyanates to afford bicyclo[6.3.0] azocine derivatives (eq 1).

Bicyclo[6.3.0] azocine ring systems are unique architectures found in several biologically active compounds. Wang and coworkers have recently designed a potent XIAP antagonist, a small molecule consisting of the bicyclic azocine as the basic template.<sup>8</sup> A number of manzamine alkaloids such as nakadomarin A and manzamine A, which exhibit potent antimalarial and antituberculosis activity, are equipped with such ring systems.<sup>9</sup> Previous approaches to bicyclo[6.3.0] heterocycles have been stepwise including a ringclosing metathesis to afford the eight-membered ring.<sup>10</sup>

Our initial efforts to effect the [4+2+2] cycloaddition focused on 1-octyne 1a and the dienyl isocyanate 2 as a mixture of E/Z isomers (Table 1, entry 1). Treatment of the substrates with  $[Rh(C_2H_4)_2Cl]_2$  modified with phosphoramidite L1 furnishes both the [4+2+2] cycloadduct 3a and the [2+2+2] cycloadduct 4a in 40% yield as an inseparable 4:1 mixture. Further investigation led to the isomerically pure diene (E)-2 as the optimal substrate to provide 3a selectively (entry 2). Despite a significant amount of unreacted isocyanate 2, the desired bicyclic azocine 3a is obtained with an exceptional enantioselectivity (99% ee). Replacing the pyrrolidinyl group on the phosphoramidite ligand with either the piperidine (L2) or azepine (L3) dramatically increases reactivity toward azocine ring formation while maintaining the high level of enantioselectivity (entries 3-4).

With optimal conditions in hand, a variety of substituted bicyclic azocines can be synthesized in good yields and superb enantiose-

Table 1. Development of the Rh-Catalyzed [4+2+2] Cycloaddition

<sup>a</sup> Conditions: **1** (1.5 equiv), **2** (0.18 mmol), Rh catalyst, L in PhMe (0.02 M) at 110 °C. <sup>b</sup> Ratio determined by <sup>1</sup>H NMR of the unpurified reaction mixture. <sup>c</sup> Isolated yield. <sup>d</sup> Determined by HPLC using a chiral stationary phase. <sup>e</sup> Combined yield of **3** and **4**.

Chart 1. Enantioselective Synthesis of [6.3.0] Bicyclic Azocines

lectivities (Chart 1). Alkyl alkynes bearing a chloride, a methyl ester, or an unprotected terminal alkyne (1b-1d) all participate smoothly to provide the corresponding cycloadducts (3b-3d).

## Scheme 1. Proposed Mechanism

Alkynes possessing functionalities such as silyl ether, phthalimide, phenyl, and Boc-protected indole at the propargylic positions (1e-1h) are well tolerated to furnish the [4+2+2] cycloadducts (3e-3h) in good yields and identical enantioselectivities.<sup>14</sup>

Cycloaddition of isocyanates with substitution at the diene portion is also feasible. For example, when 2-methyl dienyl isocyanate 5 is reacted under the standard conditions, [4+2+2] cycloadditions with various alkynes all proceed uneventfully (6a, 6e, 6j). <sup>15</sup> Reactions with aryl alkynes, however, proceed only in moderate yield. With 1-bromo-4-ethynylbenzene (1i), cycloadduct 3i can only be obtained in 35% isolated yield with the same high enantiose-lectivity.

Several aspects of these findings suggest that there may be a mechanistic divergence from our previously developed reaction. Prime among these is the invariant enantioselectivity with regard to alkyne structure as well as the failure to observe any vinylogous amide adducts in this chemistry. To gain insight into the reaction mechanism, we conducted a competition experiment between dienyl isocyanates 2 and 5. If oxidative cycloaddition occurs between the alkyne and isocyanate first (path a in Scheme 1), the ratio of products 3 and 6 should be 1:1.7h In the event, 3 is formed with 2:1 selectivity over **6**. <sup>16</sup> We suggest that this is most consistent with initial oxidative cyclization between the diene and isocyanate following path b to form V. Coordination and insertion of alkyne then provides the [4+2+2] adduct. With more reactive nucleophilic alkynes, path a becomes competitive forming rhodacycle II. Diene coordination and insertion are slow, presumably for steric reasons, allowing competitive alkyne insertion to form pyridone. The diene found in **Z-2** is a poor ligand for Rh and thus prefers path a, leading to increased amounts of both 4 and pyridone. 17

The Rh-catalyzed cycloaddition protocol allows access to synthetically useful bicyclic azocines. Dihydroxylation affords diol 7 in 72% yield for the major diastereomer (7:1 dr, eq 3a). Alternately, an  $\alpha,\beta$ -unsaturated aldehyde functionality can be readily unmasked in two simple steps from 3e, eq 3b.

In conclusion, we have developed the first enantioselective rhodium-catalyzed [4+2+2] cycloaddition of terminal alkynes and dienyl isocyanates. The process provides access to highly functionalized bicyclo[6.3.0] azocine ring systems with exceptional enantioselectivities. Further studies on the full scope of this new process are in progress.

**Acknowledgment.** We thank the NIGMS (GM080442) for support. We gratefully acknowledge Johnson Matthey for a loan of Rh salts.

**Supporting Information Available:** Experimental procedures, characterization, <sup>1</sup>H and <sup>13</sup>C NMR spectra are provided. This material is available free of charge via the Internet at http://pubs.acs.org.

- (11) This reaction also forms  $\sim\!4\%$  pyridone. Conducting this reaction at 0.06 M in 2 leads to 25% combined yield of 3 and 4 in a 3:1 ratio along with  $\sim\!10\%$  pyridone.
- (12) Further studies on [2+2+2] cycloadditions with various 1,2-disubstituted alkenyl isocyanates are ongoing.
- (13) We observe symmetrical ureas derived from the isocyanate as the only significant byproduct. No regioisomers have been observed.
- (14) Larger scale reactions may be conducted with lower catalyst loading and slightly higher concentration; with 3 mol % [Rh(C<sub>2</sub>H<sub>4</sub>) <sub>2</sub>Cl]<sub>2</sub> and 6 mol % L3 at 0.073 M using 1.5 mmol of 2, 3e is formed in 68% yield and 99% ee.
- (15) Substitution at the terminus of the diene leads to only [2+2+2] adduct under these conditions (E,E-octa-4,6-dienyl isocyanate and 1a afford 4a' in 46% yield, 46% ee). Bicyclo[6.4.0] systems are not accessible under these conditions.
- (16) At higher catalyst loading (25 mol % [Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub>Cl]<sub>2</sub>), 3 and 6 are formed quantitatively in a 4:1 ratio.
- (17) Åt 0.02 M, no pyridone is observed with E-2. At 0.1 M, we see <5% pyridone (75% yield of 3a). Also see entry 1, Table 1 and ref 11.
