**S** Supporting Information

**ABSTRACT:** Monoselective  $\gamma$ -C–H olefination and carbonylation of aliphatic acids has been accomplished by using a combination of a quinoline-based ligand and a weakly coordinating amide directing group. The reaction provides a new route for constructing richly functionalized all-carbon quaternary carbon centers at the  $\beta$ -position of aliphatic acids.

Among the many potential applications of C–H activation reactions in synthesis, functionalizing abundant, yet underutilized starting materials at strategic positions to construct common and synthetically enabling synthons has emerged as an attractive, achievable goal.<sup>1</sup> In this context, a wide range of  $sp^2$  C–H activation reactions of benzoic acids,<sup>2</sup> phenyl acetic acids and hydrocinnamic acids<sup>3</sup> have been developed. These transformations have greatly enriched the diversity of structurally limited but readily available bulky chemicals as building blocks. In parallel, we are also investigating the possibility of establishing a platform for the construction of  $\alpha$ -quaternary carbon centers from pivalic acid, the success of which will be critically dependent on the continued development of diverse racemic and asymmetric  $\beta$ -C–H functionalizations (eq 1).<sup>4</sup> However, to extend this

Sequential  $\beta$ -C–H functionalizations

Sequential  $\gamma$ -C–H functionalizations

approach toward the construction of  $\beta$ -quaternary carbon centers—another major class of versatile synthons— $\gamma$ -C–H functionalizations also need to be fully investigated and developed (eq 2). Specifically, it would be advantageous to install functional groups at the  $\gamma$ -position that are amenable for further transformations in order to construct synthetically useful intermediates. Herein we report our initial progress toward this goal through the monoselective  $\gamma$ -C–H olefination and carbonylation of a variety of  $\beta$ -quaternary amides. We found that the use of a newly developed quinoline-based ligand was essential to allow for these unprecedented transformations.

$\beta$ -C–H functionalizations of aliphatic acids using directed metalation have been extensively investigated and reported over the past decade.<sup>4,5</sup> In contrast, however, corresponding  $\gamma$ -C–H functionalizations remain largely underdeveloped.<sup>6,7</sup> Furthermore, the development of  $sp^3$  C–H olefination reactions in general remains a challenge, with relatively few examples having been reported in recent years.<sup>8</sup> This is not surprising considering the known difficulties in developing the Heck reaction using alkyl halides.<sup>9</sup> Thus, in order to establish a versatile platform for constructing  $\beta$ -quaternary carbon centers via  $\gamma$ -C–H activation, we sought to address these specific challenges. Encouraged by the recent observation that pyridine- or quinoline-based ligands can promote the  $\beta$ -C–H arylation of aliphatic amides,<sup>10</sup> we surmised that further optimization of these ligands could enable an unprecedented  $\gamma$ -C–H functionalization.

Our initial studies were guided by reaction parameters that were found to be optimal for  $\beta$ - $sp^3$  C–H olefinations.<sup>8a</sup> Unfortunately, substrate **1a** (derived from 3,3-dimethylbutanoic acid) failed to react with ethyl acrylate under these conditions. To our dismay, we found that tuning of various reaction parameters proved largely unsuccessful. We next tested a series of pyridine- and quinoline-based ligands, including 2-alkoxyquinoline **L1**, which was found to be extremely effective for promoting the  $\beta$ -arylation of  $sp^3$  C–H bonds.<sup>10</sup> However, these efforts were also met without success (eq 3).

Following these fruitless attempts, we decided to focus on the development of new ligands, beginning with tricyclic ligand **L2**, which contains a dihydropyran ring. We reasoned that by restraining the conformational freedom of the 2-alkoxy motif, one of the oxygen lone pairs would be constrained to a plane parallel to the  $\pi$ -system of the quinoline ring.<sup>11</sup> This would in

turn result in a more electron-rich ligand, potentially affecting the reactivity of the Pd(II) catalyst. As such, extensive screening of oxidants and bases was carried out with L2 as our ligand (see Supporting Information). We were pleased to find that C–H olefination of amide **1a** with ethyl acrylate in the presence of 10 mol % Pd(OAc)<sub>2</sub>, 20 mol % L2, 2.0 equiv of AgOAc, and 1.1 equiv of K<sub>2</sub>HPO<sub>4</sub> in C<sub>6</sub>F<sub>5</sub>CF<sub>3</sub> provided the desired lactam **2a** (formed after subsequent intramolecular hetero-Michael addition) in 45% yield (eq 3). However, further tuning of the reaction parameters at this stage failed to improve the yield.

To investigate the impact of ligand structure on reaction efficiency, we revisited the use of pyridine- and quinoline-based ligands L3–L6 under these newly established conditions. The consistently poor yields obtained with these ligands suggest that the pyran structural motif is crucial for the observed reactivity with L2 (Table 1). We therefore prepared analogues L7–L15

<sup>a</sup>Reaction conditions: 0.1 mmol of substrate, 50 μL of ethyl acrylate, 0.01 mmol of Pd(OAc)<sub>2</sub> (10 mol %), 0.02 mmol of Ligand, 0.2 mmol of AgOAc, 0.11 mmol of K<sub>2</sub>HPO<sub>4</sub>, 1 mL of C<sub>6</sub>F<sub>5</sub>CF<sub>3</sub>, 50 mL sealed tube, 120 °C (oil), 20 h. Yield was determined by the <sup>1</sup>H NMR spectroscopy using CH<sub>2</sub>Br<sub>2</sub> as the internal standard. <sup>b</sup>40 mol % L15, 10 mol % TEMPO, O<sub>2</sub> (1 atm), and 0.2 mmol of NaHCO<sub>3</sub> were used.

and investigated their use as ligands for this reaction. Taken together with the results obtained with ligand L2, ligands L7–L9 suggest that incorporation of electron-donating groups at C-7 and C-9 of the quinoline ring decreases the effectiveness of the ligand. In contrast, the yield was improved to 56% when a methoxy group was positioned at C-8 in L9. Addition of the electron-withdrawing trifluoromethyl or fluoro group (L10–L12) had significant detrimental effects on the observed reactivity. Mindful of the potential coordination of the methoxy

moiety with the Pd(II) center, we focused on the introduction of noncoordinative electron-donating substituents (L13–L15). Gratifyingly, we found that the use of ligand L15, bearing a *tert*-butyl group at the C-7 position, afforded lactam **2a** in 62% yield. Substitution of the dihydropyran ring with dihydrofuran decreased the yield (L16, 40%) indicating that the orientation of the lone pair on the oxygen is vital. Additionally, we also found that increased ligand loadings (40 mol %) improved the yield to 71%. Through further screening, it was discovered that by performing the reaction under an oxygen atmosphere and introducing 10 mol % co-oxidant TEMPO<sup>4d</sup> and 2 equiv of NaHCO<sub>3</sub> we could increase the yield of **2a** to 95% (see Supporting Information). We also tested other amide directing groups derived from different amines including aniline, albeit leading to a significant decrease in yields (see Supporting Information).

With these optimized conditions in hand, we proceeded to survey the scope of the reaction with substrates derived from β-quaternary center-bearing aliphatic amides (Table 2). Replacing one or two methyl groups with ethyl substituents decreased the isolated yields from 87% to 68% and 70%, respectively (2a–c). Substrates incorporating benzyl and cyclopentyl functional

groups at the  $\beta$ -position are olefinated to give the desired lactams in moderate yields (**2d**, **2e**). Both  $\gamma$ - and  $\delta$ -methoxy groups as well as  $\gamma$ -esters are tolerated, leading to moderate and synthetically useful yields (**2f–h**). Interestingly, cyclic substrates work well and provide the desired spiral lactams in 66–83% yield (**2i–l**). To our satisfaction, we found that both tetrahydropyran and piperidine structural motifs are also compatible with this olefination protocol (**2k**, **2l**).

We also investigated the use of a variety of activated olefins as coupling partners (Table 3). Olefination of **1a** with benzyl

Table 3. Scope of Olefins<sup>a</sup>

<sup>a</sup>Reaction conditions: 0.1 mmol of substrate, 0.4 mmol of alkenes, 15 mol % Pd(OAc)<sub>2</sub>, 50 mol % Ligand, 0.015 mmol of TEMPO, 0.2 mmol of AgOAc, 0.11 mmol of K<sub>2</sub>HPO<sub>4</sub> and 0.2 mmol of NaHCO<sub>3</sub>, 1 mL of C<sub>6</sub>F<sub>5</sub>CF<sub>3</sub>, O<sub>2</sub> (1 atm), 50 mL sealed tube, 130 °C (oil), 20 h. Isolated yield. <sup>b</sup>10 mol % Pd(OAc)<sub>2</sub> and 40 mol % Ligand used.

acrylate yielded **2aa** in 77% yield.  $\alpha,\beta$ -Unsaturated ketones and nitriles, however, proved less efficient. Thus, the catalyst loading was increased to 15 mol % Pd(OAc)<sub>2</sub> in order to improve the yields (**2ab–d**, 64–73% yield).

We also prepared lactam **2a** on gram scale in order to demonstrate the robustness of this newly developed transformation (Scheme 1). Furthermore, to render this reaction

Scheme 1. Gram-Scale Synthesis

even more synthetically useful, we developed a one-pot deprotonation/ring-opening procedure to convert **2a** into  $\gamma$ -olefinated ester **3a**, which can be used as a synthon for a variety of further elaborations (Scheme 2).

Scheme 2. Deprotection

Although this method is currently limited to the mono-functionalization of all-carbon  $\beta$ -quaternary carbon centers, we envision that sequential C–H functionalizations at the  $\gamma$ -carbon would provide a novel disconnection for the construction of richly functionalized all-carbon  $\beta$ -quaternary carbon centers. To this end, we developed a  $\gamma$ -carbonylation protocol utilizing ligand L15 (for ligand screening and optimization of conditions, see Supporting Information). The use of oxidant *tert*-butyl peroxide increased the NMR yield from 37% to 67%. The reaction was also successfully performed in 1 g scale to give **4a** in 61% isolated yield (Scheme 3). The monoselectivity was

Scheme 3. Sequential C–H Functionalizations

ensured through intermediate formation of imide **4a**, which is then converted to amide **5a**, a suitable substrate for our newly developed olefination reaction.<sup>4d</sup> **5a** is subsequently subjected to ethyl acrylate in the presence of Pd(II) and ligand L15 to yield lactam **2h**, which can in turn be opened to provide amide **6a**. Omission of the ester forming step in the ring-opening process ensured formation of the amide such that the four carbons on the quaternary center would be distinct.

In summary, we have developed the first example of  $\gamma$ -C(sp<sup>3</sup>)–H olefination, which provides a novel disconnection for the preparation of  $\gamma$ -olefinated aliphatic acids. The use of a newly developed quinoline-based ligand is crucial for realizing this transformation. This ligand also enables a sequential and monoselective  $\gamma$ -carbonylation/olefination procedure to afford highly functionalized all-carbon quaternary centers.
