#### Abstract

The combination of a Goodwin-Lions-type chiral N4 ligand, (R)-Ph-BINAN-H-Py ( $(R)$-3,3'-diphenyl$N^{2}, N^{2 \prime}$-bis ((pyridin-2-yl)methyl)-1,1'-binaphthyl-2,2'-diamine; L), with $\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\mathrm{cod})(\mathrm{A})(\operatorname{cod}=1,5-$ cyclooctadiene) catalyzes the hydrogenation of acetophenone (AP) to (R)-1-phenylethanol (PE) with a high enantiomer ratio (er). Almost no Ru complex forms, with A and L remaining intact throughout the reaction while generating PE quantitatively according to $[\mathrm{PE}]=k_{\text {obs }} t^{2}$. An infinitesimal amount of reactive and unstable $\mathrm{RuH}_{2} \mathrm{~L}$ (B) with $\mathrm{C}_{2}-\Lambda$-cis- $\alpha$  stereochemistry is very slowly and irreversibly generated from A by the action of $\mathrm{H}_{2}$ and L , which rapidly catalyzes the hydrogenation of AP via Noyori's donor-acceptor bifunctional mechanism. A CH- $\pi$-stabilized Si-face selective transition state, $\mathbf{C}_{s i}$, gives ( $R$ )-PE together with an intermediary Ru amide, D, which is inhibited predominantly by formation of the Ru enolate of AP. The rate-determining hydrogenolysis of $\mathbf{D}$ completes the cycle. The time-squared term relates both to the preliminary step before the cycle and to the cycle itself, with a highly unusual eight-order difference in the generation and turnover frequency of $\mathbf{B}$. This mechanism is fully supported by a series of experiments including a detailed kinetic study, rate law analysis, simulation of $t /[\mathrm{PE}]$ curves with fitting to the experimental observations at the initial reaction stage, X-ray crystallographic analyses of B-related octahedral metal complexes, and Hammett plot analyses of electronically different substrates and ligands in their enantioselectivities.

## 1. INTRODUCTION

Since the BINAP-Ru method made its debut in 1987, ${ }^{1}$ homogeneous asymmetric hydrogenation of ketones has become established as one of the most reliable strategies for the synthesis of optically active secondary alcohols. The first report on homogeneous ketone hydrogenation dates back as far as 1938, when Calvin demonstrated the catalytic activity of $\mathrm{CuOCOCH}_{3} .{ }^{2}$ In the shadow of immense efforts toward the development of homogeneous catalysts for olefin hydrogenation using $\mathrm{Rh}, \mathrm{Ru}$, or Pt complexes in combination with various organic ligands, ${ }^{3}$ little progress in this area was made until 1970, when Schrock and Osborn discovered the high utility of monocationic $\mathrm{RhH}_{2}\left(\mathrm{PPhMe}_{2}\right)_{2}$ (solvent) $)_{2}$ in the hydrogenation of acetone to 2 -propanol. ${ }^{4}$ Their discovery triggered an increase in the number of studies using chiral phosphines, ${ }^{5}$ eventually leading to the revolutionary catalyst system consisting of $\mathrm{Ru}\left(\mathrm{OCOCH}_{3}\right)_{2}$ (BINAP) and a strong Bronsted acid. ${ }^{1}$ The first generation of BINAP-Ru chemistry realized the hydrogenation of $\beta$-keto esters and a wide range of functionalized ketones with nearly perfect enantioselectivity, ${ }^{6}$ the successful development of which relies on the concept of an
intermolecular-type donor-acceptor bifunctional catalyst (In-termol-DACat) (Figure 1a). ${ }^{1 c, 7}$

A second revolution took place in 1995, when a chiral Ru catalyst consisting of $\mathrm{RuCl}_{2}(\mathrm{BINAP})(\mathrm{dmf})_{n}{ }^{8}$ and 1,2-diphenyl-ethane-1,2-diamine (DPEN) was developed. ${ }^{9}$ This BINAP-Ru-DPEN ternary system, which was based on the concept of an intramolecular-type donor-acceptor bifunctional catalyst (Intramol-DACat) (Figure 1b), shows high efficiency in the hydrogenation of unfunctionalized ketones. Since the start of this apparent trend of BINAP-Ru systems, a vast number of hydrogenation-active Ru complexes with trivalent phosphorus ligating atoms have been reported. ${ }^{10}$ Their effectiveness has been examined and compared to that of the "privileged"11 BINAP chiral catalyst and its derivatives. Nevertheless, no omnipotent catalyst exists even now, and new frameworks for designing asymmetric catalysts are required.

From this viewpoint, nitrogen-based ligands have hidden potential because they have not been extensively researched as

yet, although Ohgo et al. reported the first asymmetric hydrogenation of ketones catalyzed by Co(II)(bisdimethylglyoximato)/quinine in 1971, ${ }^{12}$ around the same time as Schlock-Osborn's report. ${ }^{4}$ After three unproductive decades, there is now increasing attention on all nitrogenligating systems. The Goodwin-Lions-type tetradentate $\mathrm{sp}^{2} \mathrm{~N} /$ $s^{3}{ }^{3} \mathrm{NH}$ linear N 4 ligand $R$-BINAN- $R^{\prime}$-Py ( $3,3^{\prime}-R, R-N^{2}, N^{2 \prime}$ -bis((6-R'-pyridin-2-yl)methyl)-1,1'-binaphthyl-2, $2^{\prime}$-diamine $)^{13,14}$ is one of the key examples setting a precedent in this new trend. ${ }^{15}$ A combination of the nonphosphine ligand Ph -BINAN-H-Py ( $\mathbf{L}$ ) and the $\mathrm{Ru} \pi$-allyl complex $\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\right.$ $\left.\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}($ cod $)(\mathrm{A})^{16}$ quantitatively hydrogenates various aromatic ketones with a substrate/catalyst (S/C) ratio of $>10000$ to give the secondary alcohol with an enantiomer ratio (er) of up to $>99: 1 .{ }^{13}$ Most interestingly, the reaction proceeds with almost no formation of any Ru complexes. Here, we would like to present a mechanism explaining this unusual phenomenon and the origin of enantioselection in the $(R)-L /$ A-catalyzed asymmetric hydrogenation of acetophenone (AP) to $(R)-1$-phenylethanol $((R)-\mathrm{PE})$ (Figure 2).

## 2. RESULTS AND DISCUSSION

### 2.1. Characteristic Features of ( $R$ )-Ph-BINAN-H-Py ((R)-

L). 2.1.1. $\Lambda$-cis- $\alpha$ Selectivity. Theoretically, the linear

Figure 2. Standard conditions used for this mechanistic study of asymmetric hydrogenation of acetophenone ( $\mathbf{A P}$ ) catalyzed by the (R)-Ph-BINAN-H-Py/Ru $\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\operatorname{cod}) \quad((R)-L / A)$ combined system ( $\mathrm{PE}=1$-phenylethanol).
tetradentate chiral ligand $(R)-\mathrm{L}$ can form five geometrical isomers in an octahedral metal complex ${ }^{13}-C_{2}-\Lambda$-cis- $\alpha$-, $C_{2}-\Delta$ -cis- $\alpha$-, $C_{1}-\Delta$-cis- $\beta$-, $C_{1}-\Lambda$-cis- $\beta$-, and $C_{2}$-trans-isomers-although the $C_{2}$ symmetric $\Delta$-cis- $\alpha$ and $C_{1}$ symmetric $\Lambda$-cis- $\beta$ isomers are unlikely because of their highly distorted structures. These isomers are in equilibrium with each other (Figure 3a), and the

Figure 3. Equilibrium between three stereoisomers of ( $R$ )-Ph-BINAN-$\mathrm{H}-\mathrm{Py}-\mathrm{RuH}_{2}$ (B) (a) and (R)-H-BINAN-H-Py- $\mathrm{RuH}_{2}(\mathrm{~b})$. Red arrows indicate a steric repulsion.
overall catalyst performance is the average of each isomer's own reactivity and enantioselectivity. ${ }^{17}$ A density functional theory (DFT) calculation of an imaginary $\mathrm{RuH}_{2}((R)-\mathrm{L})$ (B) complex using the B3LYP/LANL2DZ set showed that the relative Gibbs free energies of $\Delta$-cis- $\beta$ - $\mathbf{B}$ and trans-B isomers are, respectively, 14.8 and $19.2 \mathrm{kcal} / \mathrm{mol}$ higher than that of $\Lambda$-cis- $\alpha$-B. Steric repulsion (red arrow) between the $C(3)$ phenyl group of the naphthalene ring and the pyridylmethyl group in the $\Delta$-cis- $\beta$ and trans isomers would shift the equilibrium to the $\Lambda$-cis- $\alpha$-B side. The energy difference indicates that the $\Delta$-cis- $\beta$-B and trans-B isomers exist at, respectively, only one-trillionth and one hundred-trillionth of the level of $\Lambda$-cis- $\alpha$-B. This property is advantageous for unifying the catalytic species to enhance catalyst performance. Regarding the original Goodwin-Lions ligand, ${ }^{14}$ which has no $3,3^{\prime}$-phenyl substituents of $(R)-\mathrm{L}$, the $C_{1}$ symmetric $\Delta$-cis- $\beta$ isomer is the most stable (Figure 3b) according to the same DFT calculation. The existence of the two different possible reaction sites in the $\Delta$-cis- $\beta$ isomer may complicate the reaction pathways. In this sense, the $C_{2}$ symmetric $\Lambda$-cis- $\alpha$-B isomer is simple.
2.1.2. Metal Capturing Ability. $\left[\mathrm{Ru}((\mathrm{R})-\mathrm{L})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\right]$ $\left(\mathrm{PF}_{6}\right)_{2}(\mathbf{1})$ was quantitatively prepared by mixing $(R)-\mathrm{L}$ and $\left[\mathrm{Ru}\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\right]\left(\mathrm{PF}_{6}\right)_{2}{ }^{18}$ in $\mathrm{CH}_{3} \mathrm{CN}$ at room temperature (rt) for 48 h , and yellowish prism crystals (melting point $(\mathrm{mp})=245{ }^{\circ} \mathrm{C}$ ) were obtained in $68 \%$ yield from a $\mathrm{CHCl}_{3}-$ THF (THF $=$ tetrahydrofuran) solvent system. Ru-$\left(\mathrm{OCOCH}_{3}\right)_{2}-((R)-\mathrm{L})$ (2) was also quantitatively obtained from $\mathrm{Ru}_{2}\left(\mathrm{OCOCH}_{3}\right)_{4}{ }^{19}\left(\mathrm{CH}_{3} \mathrm{OH}, \mathrm{rt} / 48 \mathrm{~h}\right.$ then $\left.60{ }^{\circ} \mathrm{C} / 2 \mathrm{~h}\right)$ and crystallized as reddish-brown platelets ( $\mathrm{mp}=225^{\circ} \mathrm{C}$ ) in $60 \%$ yield from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and hexane. In a similar way, $\mathrm{Mn}(\mathrm{OTf})_{2}((R)-\mathrm{L})\left(60{ }^{\circ} \mathrm{C}, 30 \mathrm{~min}, \mathrm{CH}_{3} \mathrm{CN}\right), \mathrm{Fe}(\mathrm{OTf})_{2}((R)-$ L) $\left(25{ }^{\circ} \mathrm{C}, 1 \mathrm{~h}, \mathrm{THF}\right)$, and $\mathrm{Cu}(\mathrm{OTf})_{2}((R)-\mathrm{L})\left(25{ }^{\circ} \mathrm{C}, 1 \mathrm{~h}\right.$, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ ) were prepared. ${ }^{20}$ The molecular structures in crystal are shown in Figure 4, reflecting a general tendency of $(R)$-Ph-BINAN-H-Py ligand ( $(R)-\mathrm{L})$ to form the $C_{2}-\Lambda$-cis- $\alpha$ isomer.

(e)

Figure 4. Molecular structures of (a) $[\mathrm{Ru}((R)-\mathrm{Ph}-\mathrm{BINAN}-\mathrm{H}-\mathrm{Py})$ $\left.\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}$, (b) $\mathrm{Ru}\left(\mathrm{OCOCH}_{3}\right)_{2}((\mathrm{R})$-Ph-BINAN-H-Py), (c) $\mathrm{Mn}(\mathrm{OTf})_{2}\left((\mathrm{R})\right.$-Ph-BINAN-H-Py), (d) $\mathrm{Fe}(\mathrm{OTf})_{2}((R)$-Ph-BINAN-H$\mathrm{Py})$, and (e) $\mathrm{Cu}(\mathrm{OTf})_{2}((R)-\mathrm{Ph}-\mathrm{BINAN}-\mathrm{H}-\mathrm{Py})$ in the crystalline state. $\mathrm{OTf}=\mathrm{OSO}_{2} \mathrm{CF}_{3}$.

The structure of $\Lambda$-cis- $\alpha$ in solution was confirmed by ${ }^{1} \mathrm{H}$ NMR analyses of two diamagnetic Ru complexes, $[\mathrm{Ru}((R)-$ L) $\left.\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}(\mathbf{1})$ and $\mathrm{Ku}\left(\mathrm{OCOCH}_{3}\right)_{2}((\mathrm{R})-\mathrm{L})$ (2). For both complexes, only one set of signals was observed in the ${ }^{1} \mathrm{H}$ NMR spectra: ${ }^{20}(R)-1(\delta 4.23(\mathrm{dd}, J=18.6$ and 5.5 Hz , $\left.\mathrm{CH}_{R} H_{S}\right), 4.58\left(\mathrm{dd}, J=18.6\right.$ and $\left.8.9 \mathrm{~Hz}, \mathrm{CH}_{R} \mathrm{H}_{S}\right), 6.35(\mathrm{dd}, J=$ 8.9 and $5.5 \mathrm{~Hz}, \mathrm{NH})$ ) and $(R)-2\left(\delta 1.46\left(\mathrm{~s}, \mathrm{CH}_{3} \mathrm{COO}\right), 3.97\right.$ (dd, $J=17.2$ and $\left.6.0 \mathrm{~Hz}, \mathrm{CH}_{R} H_{S}\right), 4.29(\mathrm{dd}, J=17.2$ and 8.1 $\left.\mathrm{Hz}, \mathrm{CH}_{R} \mathrm{H}_{S}\right), 9.13(\mathrm{dd}, J=8.1$ and $6.0 \mathrm{~Hz}, \mathrm{NH})$ ). These simple spectra were consistent with both complexes $\mathbf{1}$ and $\mathbf{2}$ having a symmetric $C_{2}-\Lambda$-cis- $\alpha$ structure. In addition, this $\Lambda$-cis- $\alpha$ geometry in solution phase was supported by the observation of a nuclear Overhauser effect (NOE) between the closely located naphthalene $\mathrm{C}(8) \mathrm{H}$ and methylene $\mathrm{H}_{S}[(R)-1,1.6 \%$
(irradiation of $\mathrm{H}_{S}$ ) and $1.0 \%$ (irradiation of $\left.\mathrm{C}(8) \mathrm{H}\right) ;(R)-\mathbf{2}$, $3.5 \%$ (irradiation of $\mathrm{H}_{S}$ )].
2.2. Proposed Reactive Species: $\Lambda$-cis- $\alpha-\mathrm{RuH}_{2}((R)-\mathrm{L})$ (B). 2.2.1. Catalyst Performance. The above preformed Ru complexes $(2 \mathrm{mM}), \Lambda$-cis- $\alpha$ - $\left[\mathrm{Ru}((R)-\mathrm{L})\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}(\mathbf{1})$ and $\Lambda$-cis- $\alpha-\mathrm{Ru}\left(\mathrm{OCOCH}_{3}\right)_{2}((R)-\mathrm{L})$ (2), quantitatively hydrogenate acetophenone (AP) ( 2 M ) in 2-propanol ( $\mathrm{iPrOH} \mathrm{)}$ containing potassium tert-butoxide ( $t \mathrm{BuOK}$ ) $(20 \mathrm{mM})$ to give $(R)$-1-phenylethanol $((R)-\mathbf{P E})$ and (S)-PE with an er of, at most, 93:7 for complex $1\left(\mathrm{H}_{2}, 100 \mathrm{~atm}, 50^{\circ} \mathrm{C}, 24 \mathrm{~h}\right)$ and 84:16 for complex $2\left(\mathrm{H}_{2}, 50 \mathrm{~atm}, 25^{\circ} \mathrm{C}, 24 \mathrm{~h}\right) .{ }^{20}$ In contrast to the present (R)-L/A combined system (Figure 2) and against expectation, the catalyst performance of that system was low. The $\mathrm{RuX}_{2}$-L-type complexes require an excess amount of base, because the balance point lies toward the left side in the equilibria of both " $\mathrm{RuX}_{2}-\mathbf{L}+\mathrm{H}_{2} \rightleftarrows \mathrm{RuHX}-\mathbf{L}+\mathbf{H X}$ " and " $\mathrm{RuHX}-\mathbf{L}+\mathrm{H}_{2} \rightleftarrows \mathrm{RuH}_{2}-\mathbf{L}+\mathrm{HX}$ ". ${ }^{21 \mathrm{a}, 22 \mathrm{c}}$ The reaction system might be complicated by the remaining $t \mathrm{BuOK}$ and coproduced salts such as $\mathrm{KPF}_{6}$ and $\mathrm{KOCOCH}_{3}$, which might disturb the clean generation of the presumed reactive species, $\Lambda$-cis- $\alpha$ -$\mathrm{RuH}_{2}((R)$-L) (B).
2.2.2. Trial for Detection of B. Related mechanistic studies on the hydrogenation of ketones using Ru complexes of phosphine-containing ligands suggest that a $\mathrm{RuH}_{2}$ mechanism operates. ${ }^{21-24}$ Furthermore, $\mathrm{RuH}_{2}$ complexes can be prepared in high yields from $\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}$ (diphosphine) and $\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\operatorname{cod})(\mathbf{A}) / \mathrm{PNP}$ ligand. ${ }^{25}$ On the basis of this information, we tried to detect either $\mathrm{RuH}_{2}((R)$ L) (B) or any Ru complexes from $\mathbf{A}$ and $\mathbf{L}$ with or without $\mathrm{H}_{2}$ and at 25 or $60^{\circ} \mathrm{C}$, but in vain (Table 1). ${ }^{20}$ Nothing occurred at $25^{\circ} \mathrm{C}$, but a black precipitate, most probably a $\mathrm{Ru}(0)$ cluster

${ }^{a}$ Conditions: $[\mathbf{A}]=[\mathbf{L}]=10 \mathrm{mM} ; 24 \mathrm{~h} .{ }^{b}$ Determined by the ${ }^{1} \mathrm{H}$ NMR analysis. ${ }^{c}$ IB $=$ isobutene, $\mathbf{I B D}=$ isobutene dimer ( 2,5 -dimethylhexa1,5 -diene). ${ }^{d}$ Black precipitate was observed. No ${ }^{1}$ H NMR signal except for those of $\mathbf{A}$ and $\mathbf{L}$ was detected. ${ }^{e}$ In the absence of $\mathbf{L}$. ${ }^{\text {fi }} \mathrm{H}$ NMR was measured in $\mathrm{C}_{6} \mathrm{D}_{6}$ after evaporation.
(" $\mathrm{Ru}(0)$ ") or a RuH cluster (" RuH "), was generated at an elevated temperature. Figure 5 shows the possible pathways

Figure 5. Supposed decomposition pathways from $\mathbf{A},(R)-\mathbf{L}$, and $\mathrm{H}_{2}$ to a black precipitate. $\mathbf{L}^{\prime}=\operatorname{cod}$, solvent, $\mathrm{H}_{2},(R)$ - $\mathbf{L}$, etc.; $n=1-4$.
from $\mathbf{A},(R)-\mathbf{L}$, and $\mathrm{H}_{2}$ to the black precipitate. $\mathbf{A}^{\prime}$ is an imaginary bismethallyl species, in which cod of $\mathbf{A}$ is fully or partly replaced with solvent, $\mathrm{H}_{2},(R)$-L, etc. In route (a), coupling of the two methallyl ligands in $\mathbf{A}$ or $\mathbf{A}^{\prime}$ gives isobutene dimer (IBD), 2,5-dimethylhexa-1,5-diene, and " $\mathrm{Ru}(0)$ ". ${ }^{26}$ In route (b), $\mathbf{A}$ or $\mathbf{A}^{\prime}$ is converted to isobutene (IB) and a trimethylenemethane $\mathrm{Ru}(\mathrm{II})$ species, ${ }^{27}$ which decomposes to " $\mathrm{Ru}(0)$ " via " RuH ". In route (c), A or $\mathbf{A}^{\prime}$ directly reacts with $\mathrm{H}_{2}$ to generate IB and " RuH ", ${ }^{25}$ which decomposes to " $\mathrm{Ru}(0)$ ". In all routes, the decomposition may proceed via $\mathrm{RuH}_{2}((R)-\mathrm{L})$ (B).

In discussing the results shown in Table 1, care must be taken because (i) IB and IBD were not quantitatively detected and (ii) the ${ }^{1} \mathrm{H}$ NMR spectra tended to broaden. The black precipitate may absorb these alkenes to some extent, and aggregates of RuH species may be formed. ${ }^{25,28}$ With such uncertainty in mind, the results were examined. In $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CDOH}$, which is the solvent of choice in the present asymmetric hydrogenation, no reaction of $\mathbf{A}$ with $\mathbf{L}$ occurred at $25^{\circ} \mathrm{C}$ even after 24 h at 0 or 50 atm of $\mathrm{H}_{2}$ (entries 1 and 4). An increase in temperature to $60^{\circ} \mathrm{C}$ at 50 atm of $\mathrm{H}_{2}$ decomposed $25 \%$ of A to generate a black precipitate together with $8 \%$ of IB (entry 5). Little IBD was detected, negating route (a). Removal of $\mathrm{H}_{2}$ from the condition of entry 5 also led to a black precipitate, but, in this case, IB and IBD were generated in ca. 1:3 ratio (entry 2). Routes ( $a-c$ ) may proceed in parallel. Interestingly, in the absence of $\mathbf{L}$, nothing occurred (entries 2 and 3). The NH proton of $\mathbf{L}$ or association of $\mathbf{L}$ with $\mathbf{A}$ may accelerate the decomposition. ${ }^{29}$ A basically similar tendency was observed in aprotic solvents such as $\mathrm{C}_{6} \mathrm{D}_{6}$ and THF- $d_{8}$ (entries 6-15) in terms of the black precipitate. Unlike the case with $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CDOH}$, however, IBD was detected at 50 atm of $\mathrm{H}_{2}$ (entries 10 and 15). Routes (b) and (c) are suppressed in aprotic solvents for some reason. In hexane, $\mathbf{A}$ decomposed at $60^{\circ} \mathrm{C}$ regardless of whether $\mathrm{H}_{2}$ or $\mathbf{L}$ was present or not (entries 16-20).

Although the decomposition occurred only at an elevated temperature, the series of results in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CDOH}$ are not inconsistent with the view that an infinitesimal amount of $\mathbf{B}$ is formed via hydrogenolysis of methallyl groups by two hydrogen molecules under the real hydrogenation conditions at $25^{\circ} \mathrm{C}$ (see sections 2.4 and 2.5). As compared with the phosphorus atom-ligating $\mathrm{RuH}_{2}, \mathbf{B}$, which possesses electron-donating and non- $\pi$-acceptable $s p^{3} \mathrm{~N}$ atoms trans to two hydrides, would be significantly destabilized to decompose without AP. Furthermore, replacement of cod in A would be more difficult with $\mathbf{L}$ than with the phosphorus-based ligand.
2.2.3. In Situ NMR Study. Figure 6 shows the ${ }^{1} \mathrm{H}$ NMR spectra of the reaction mixture before and after introduction of

Figure 6. In situ ${ }^{1} \mathrm{H}$ NMR monitoring of the hydrogenation of acetophenone (AP, 75 mM ) to 1-phenylethanol (PE) in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CDOD}$ containing (R)-Ph-BINAN-H-Py $((R)-\mathrm{L}, 10 \mathrm{mM})$, $\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\operatorname{cod})(\mathrm{A}, 10 \mathrm{mM})$, and $t \mathrm{BuOK}(6.7 \mathrm{mM})$ at $25{ }^{\circ} \mathrm{C}$. (a) Spectrum obtained 1.5 h after allowing the reaction mixture to stand without $\mathrm{H}_{2}$. (b) Spectrum obtained 27 h after applying 50 atm of $\mathrm{H}_{2}$ pressure to the reaction in (a) in a pressure-tight sapphire tube. The signal/noise ratio in spectrum (b) is calculated to be 177 , as shown in the inset. The signals are indicated by $O((R)-L), \triangle(A), \times$ (AP), and $\square$ (PE).
$\mathrm{H}_{2}\left([(R)-\mathrm{L}]_{0}=[\mathbf{A}]_{0}=10 \mathrm{mM},[\mathrm{BuOK}]=6.7 \mathrm{mM},[\mathrm{AP}]_{0}=75\right.$ $\left.\mathrm{mM}, 50 \mathrm{~atm} \mathrm{H}_{2},\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CDOD}, 25^{\circ} \mathrm{C}, 27 \mathrm{~h}\right)$. In the ${ }^{1} \mathrm{H}$ NMR spectrum obtained 1.5 h after the addition of all components except for $\mathrm{H}_{2}$ (Figure 6a), sets of signals corresponding to $\mathbf{A}$ $(\triangle),(R)-\mathrm{L}(\mathrm{O}), \mathbf{A P}(\times)$, and $t \mathrm{BuOK}$ were independently observed, although the $\mathrm{CH}_{3}$ signal intensity of AP had decreased owing to hydrogen-deuterium (H/D) exchange via formation of the enolate of AP. After pressurizing the system to 50 atm of $\mathrm{H}_{2}$, the AP signals $(\times)$ disappeared and the PE product signals ( $\square$ ) appeared, whereas there was no change in the signals of $\mathbf{A}$ or $(R)-\mathbf{L}$. The $R / S$ ratio of the PE product formed was $86: 14$. Within the limits of the signal-to-noise (S/ $\mathrm{N})$ ratio (177), no $\mathrm{Ru}-(R)-\mathrm{L}$ complex formed. Nonetheless, we believe that a very tiny amount of a chiral and reactive species $\mathbf{B}([\mathbf{B}]<10 / 177 \mathrm{mM}=0.0565 \mathrm{mM}$ ) is slowly generated under the hydrogenation conditions and is operating in this catalysis. B would survive only in the presence of the substrate AP.
2.3. Time-Conversion ( $t /[\mathrm{PE}]$ ) Curves. The time course of the IR C $=\mathrm{O}$ stretching band intensity of AP at $1690 \mathrm{~cm}^{-1}$ was obtained by use of a total internal reflectance measurement system during the hydrogenation of AP using the (R)-L/A combined catalyst under the standard conditions $\left([(R)-\mathbf{L}]_{0}=\right.$ $[\mathbf{A}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM},[\mathrm{AP}]_{0}=2 \mathrm{M}, 50 \mathrm{~atm} \mathrm{H}_{2}, i \mathrm{PrOH}, 25$ $\left.{ }^{\circ} \mathrm{C}\right) .{ }^{20}$ The data were converted to the $t /[\mathrm{PE}]$ curve shown in Figure 7a, together with those obtained at $[\mathbf{A P}]_{0}=0.5$ and 1 M .

Figure 7. (a) Intriguing phenomenon observed in the $t /[\mathrm{PE}]$ relation at $[\mathbf{A P}]_{0}=0.5,1$, and 2 M (conditions: $[(R)-\mathrm{L}]=[\mathbf{A}]=[t \mathrm{BuOK}]=2$ $\mathrm{mM}, 50 \mathrm{~atm} \mathrm{H}_{2}, i \operatorname{PrOH}, 25^{\circ} \mathrm{C}$ ). (b) Plot of [PE] versus $t^{2}$.

The following intriguing observations can be made from the three $t /[\mathrm{PE}]$ curves: (i) the velocity of $\mathbf{P E}$ production ( $\mathrm{d}[\mathbf{P E}] /$ $\mathrm{d} t$ ) increases exponentially in the early stages but follows a rather straight relationship in the later stages; (ii) $\mathrm{d}[\mathrm{PE}] / \mathrm{d} t$ does not decelerate even at the very final stage; and (iii) $\mathrm{d}[\mathbf{P E}] / \mathrm{d} t$ decreases as $[\mathbf{A P}]_{0}$ increases. Observation (i) is not inconsistent with the scenario that the reactive species $\mathbf{B}$ is gradually generated during the course of the reaction, but it argues against the possible existence of an acceleration effect of product PE. The slight rate deceleration $\left(0.28 \mathrm{M} \mathrm{h}^{-1}\left([\mathbf{A P}]_{0}=\right.\right.$ $0.5 \mathrm{M}), 0.27 \mathrm{M} \mathrm{h}^{-1}(1 \mathrm{M})$, and $0.26 \mathrm{M} \mathrm{h}^{-1}(2 \mathrm{M})$ ) in the straight line region of $70-100 \%$ conversion would instead indicate very weak product inhibition. Observation (ii) implies a zeroth-order dependence on AP concentration in the reaction system, while observation (iii) clearly shows that the reaction is inhibited by the initial concentration of AP ([AP $]_{0}$ ). The difference between the reaction profile in the early stages and that in the later stages may be ascribed not only to the timedependent change in $[\mathbf{A P}],[\mathbf{P E}]$, and $[\mathbf{B}]$ but also to the decomposition of $\mathbf{B}$ at a lower concentration of AP. The rate is not enhanced as much as expected in the later stages, where the concentration of $\mathbf{B}$ increases. The balance between $\mathbf{B}$ generation and decomposition may result in observation (i). To simplify the subsequent discussion, we will focus on the kinetic scheme of the present asymmetric hydrogenation only in the early stages ( $0-30 \%$ conversion of $\mathbf{A P}$ ) of the reaction.
2.4. Supposed Catalytic Cycle and Rate Law Analysis. On the basis of the above experimental results and the mechanism reported for other $\mathrm{Ru}(\mathrm{II})$-catalyzed hydrogenations, ${ }^{21-24}$ we supposed the kinetic model shown in Figure 8, in which there are two processes occurring in parallel. One is the preliminary step with the rate constant $k_{0}$ from $\mathrm{Ru}(\pi$ $\left.\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\mathrm{cod})(\mathrm{A}) /(\mathrm{R})$-Ph-BINAN-H-Py ( $\left.(R)-\mathrm{L}\right) /$ $\mathrm{H}_{2}$ to the reactive and unstable $\Lambda$-cis- $\alpha$-B intermediate, and the other is the catalytic cycle itself for hydrogenation of AP to PE based on the Intramol-DACat mechanism (Figure 1b). In the absence of AP, the short-lived $\mathbf{B}$ easily decomposes by the liberation of $\mathbf{L}$, while in the presence of $A P$, the polarized $\mathrm{H}^{\delta+}-$

Figure 8. Reaction pathway and enantioface selection in the Intramol-DACat-based hydrogenation of acetophenone (AP) using ( $R$ ) - Ph -BINAN-H-Py $((R)-L)$ and $\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\operatorname{cod})(\mathbf{A})$.
$\mathrm{N}^{\delta-}--\mathrm{Ru}^{\delta+}-\mathrm{H}^{\delta-}$ moiety of the 18 e Ru dihydride $\mathbf{B}$ captures the similarly polarized $\mathrm{C}^{\delta+}=\mathrm{O}^{\delta-}$ of AP to move to transition state C. In this charge-alternating six-atom system, the red and blue hydrogen atoms are delivered to the $\mathrm{C}=\mathrm{O}$ double bond to release PE together with generation of the 16 e Ru amide D , which would have a trigonal bipyramidal structure with a $\mathrm{Ru}=$ N double-bond character. ${ }^{21 \mathrm{c}}$ The coordinatively unsaturated $\mathbf{D}$ interacts with $\mathrm{H}_{2}$ in an $\eta^{2}$ manner to form $\mathbf{F}$, which undergoes heterolytic cleavage to reproduce the chain carrier $\mathbf{B}$, thereby completing the catalytic cycle. The rate of the cycle would be determined by the $\mathbf{D}->\mathbf{B}$ step with $k_{2}$ and not by the $\mathbf{B}->\mathbf{D}$ step with $k_{1}\left(k_{2} \ll k_{1}\right) .{ }^{21 \mathrm{c}}$ The Ru amide $\mathbf{D}$ interacts not only with $\mathrm{H}_{2}$ but also with AP, PE, and $i \mathrm{PrOH}$ to form equilibria with the corresponding Ru enolate and Ru alkoxide $\mathrm{E}_{\mathrm{OH}_{2}}$ and the equilibrium constant $K_{\mathrm{QH}}$, thereby causing inhibition. ${ }^{2}$

In the present particular case, the catalyst precursor $\mathbf{A}$ is consumed by the action of $\mathrm{H}_{2}$ and $\mathbf{L}$ to generate $\mathbf{B}$ with an extraordinarily slow rate on the time scale of hydrogenation, enabling $[\mathbf{A}]$ and $[\mathbf{L}]$ to be approximated by $[\mathbf{A}]_{0}$ and $[\mathbf{L}]_{0}$, respectively $\left([\mathbf{A}] \approx[\mathbf{A}]_{0}\right.$ and $\left.[\mathbf{L}] \approx[\mathbf{L}]_{0}\right)$. Hydrogen pressure $\left(\left[\mathrm{H}_{2}\right]\right)$ and $t \mathrm{BuOK}$ concentration $([t \mathrm{BuOK}])$ do not change during the reaction. Therefore, the total concentration of the Ru species in the cycle ( $\left[\mathrm{Ru}_{\text {cycle }}\right]$ ) can be expressed as $k_{0}[\mathbf{A}]_{0}^{l}[\mathbf{L}]_{0}^{m}\left[\mathrm{H}_{2}\right]^{n} t^{20}$ Furthermore, under the condition of $k_{2}$

Figure 9. Dependence of the rate constant $k_{\text {obs }}$ on $\left[\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}_{\left(\mathrm{CH}_{3}\right)} \mathrm{CH}_{2}\right)_{2}(\operatorname{cod})(\mathbf{A})\right]_{0},[(R)-\mathrm{Ph}-\mathrm{BINAN}-\mathrm{H}-\mathrm{Py}((R)-\mathrm{L})]_{0}, \mathrm{H}_{2}$ pressure $\left(p \mathrm{H}_{2}\right)$, and [acetophenone (AP) $]_{0}$ in the hydrogenation of $\mathbf{A P}$ in $i \mathrm{PrOH}$ at $25^{\circ} \mathrm{C}$. (a) Plot of $k_{\text {obs }}$ as a function of $[\mathbf{A}]_{0}$ from 0.5 to $4 \mathrm{mM}\left([(R)-\mathbf{L}]_{0}=[t \mathrm{BuOK}]\right.$ $\left.=2 \mathrm{mM},[\mathrm{AP}]_{0}=2 \mathrm{M}, 50 \mathrm{~atm} \mathrm{H}_{2}\right)$. (b) Plot of $k_{\text {obs }}$ as a function of $[(R)-\mathrm{L}]_{0}$ from 0.1 to $4 \mathrm{mM}\left([\mathbf{A}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM},[\mathrm{AP}]_{0}=2 \mathrm{M}, 50 \mathrm{~atm} \mathrm{H}_{2}\right)$. (c) Plot of $k_{\text {obs }}$ as a function of $p \mathrm{H}_{2}$ from 25 to $90 \mathrm{~atm}\left([\mathbf{A}]_{0}=[(R)-\mathbf{L}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM},[\mathbf{A P}]_{0}=2 \mathrm{M}\right)$. (d) Plot of $k_{\mathrm{obs}}$ as a function of $p \mathrm{H}_{2}{ }^{3}$ of graph (c). (e) Plot of $k_{\text {obs }}$ as a function of $[\mathbf{A P}]_{0}$ from 0.5 to $4 \mathrm{M}\left([\mathbf{A}]_{0}=[(R)-\mathrm{L}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM}, 50 \mathrm{~atm} \mathrm{H}_{2}\right)$. (f) Plot of $k_{\mathrm{obs}}$ as a function of $1 /[\mathbf{A P}]_{0}$ of graph (e).
$\ll k_{1}$, the $\mathrm{Ru}_{\text {cycle }}$ is distributed mainly to $\mathbf{D}$ and $\mathrm{E}_{\mathrm{QH}}\left(\left[\mathrm{Ru}_{\text {cycle }}\right]=\right.$ $\left.[\mathrm{D}]+\Sigma\left[\mathrm{E}_{\mathrm{QH}}\right]=[\mathrm{D}]\left(1+\Sigma K_{\mathrm{QH}}[\mathbf{Q H}]\right)\right)$, leading to eq 1 .

$$
\begin{equation*}
[\mathbf{D}]=k_{0}[\mathbf{A}]_{0}^{l}[\mathbf{L}]_{0}^{m}\left[\mathrm{H}_{2}\right]^{n} t /\left(1+\sum K_{\mathbf{Q H}}[\mathbf{Q H}]\right) \tag{1}
\end{equation*}
$$

Steady-state assumption for $\mathbf{D}$ gives $\mathrm{d}[\mathbf{P E}] / \mathrm{d} t=k_{2}[\mathbf{D}]\left[\mathrm{H}_{2}\right]=$ $k_{0} k_{2}[\mathbf{A}]_{0}^{l}[\mathbf{L}]_{0}^{m}\left[\mathrm{H}_{2}\right]^{n+1} t /\left(1+\Sigma K_{\mathrm{QH}}[\mathrm{QH}]\right)$. With the definitions of $\Sigma K_{\mathrm{QH}}[\mathbf{Q H}]=K_{\mathrm{AP}}[\mathbf{A P}]+K_{(R)-\mathrm{PE}}[(R)-\mathrm{PE}]+K_{(S)-\mathrm{PE}}[(S)-\mathrm{PE}]$ $+K_{i \mathrm{PrOH}}[\mathrm{PrOH}]$ and $K_{\mathrm{PE}}[\mathrm{PE}]=K_{(R) \cdot \mathrm{PE}}[(R)-\mathrm{PE}]+K_{(S)-\mathrm{PE}}[(S)-$ $\mathrm{PE}]=Z \mathrm{~K}_{\mathrm{AP}}[\mathrm{PE}]$, integration of the $\mathrm{d}[\mathrm{PE}] / \mathrm{d} t$ equation from 0 to $t$ followed by the second-order Taylor expansion at $t=0$ gives eq $2 .{ }^{20}$

$$
\begin{align*}
& {[\mathbf{P E}]=\left(k_{0} k_{2}[\mathbf{A}]_{0}^{l}[\mathbf{L}]_{0}^{m}\left[\mathrm{H}_{2}\right]^{n+1} / 2\left(K_{\mathrm{AP}}[\mathbf{A P}]_{0}+K_{i \mathrm{PrOH}}[\mathrm{PrOH}]\right.\right.} \\
& \quad+1)) t^{2}=k_{\mathrm{obs}} t^{2} \tag{2}
\end{align*}
$$

Consistent with eq 2, time-squared plotting of the $t /[\mathrm{PE}]$ relations in Figure 7a gave straight lines, at least in the early reaction stages (Figure 7 b ), implying that the preliminary step from ( $R$ )-L/A/ $\mathrm{H}_{2}$ to $\mathbf{B}$ and the catalytic cycle converting AP to PE are operating in parallel.
2.5. Reaction Orders for $[A]_{0},[\mathrm{~L}]_{0},\left[\mathrm{H}_{2}\right]\left(\mathrm{pH} \mathrm{H}_{2}\right)$, and $[\mathrm{AP}]_{0}$. The time-squared equation, $[\mathrm{PE}]=k_{\text {obs }}{ }^{2}$, was used to deduce the reaction orders for $\mathbf{A},(R)-\mathbf{L}, ~ p \mathrm{H}_{2}$, and AP. The values of $k_{\text {obs }}$ in all of the kinetic experiments were derived by using data obtained at the initial stages of the reaction, between $0 \%$ and $30 \%$ conversion, where the linearity is the highest (Figure 7b, red line). ${ }^{20}$ The relationship between $k_{\text {obs }}$ and each parameter is shown in Figure 9a-f.

The plots of $k_{\text {obs }}$ versus $[\mathbf{A}]_{0}$ from 0.5 to 4 mM gave a reasonably linear relationship from the origin with a correlation coefficient of 0.964 , indicating a first-order dependence on $[\mathbf{A}]_{0}$ ( $l=1$ in eq 2 ) (Figure 9a). The rate was essentially not affected by $[\mathbf{L}]_{0}(0.1-4 \mathrm{mM})(m=0$ in eq 2$)$ within the range of error distribution (Figure 9b). The $k_{\text {obs }}$ value exponentially increases as $p \mathrm{H}_{2}$ increases from 25 to 90 atm (Figure 9c) according to an
accurate cubic function. Figure 9d shows a third-order plot affording a straight line from the origin with a correlation coefficient of 0.978 , establishing $n+1=3$ in eq 2 . In contrast to the acceleration effect of $p \mathrm{H}_{2}$ on the rate, the $k_{\text {obs }}$ value exponentially decreases as $[\mathbf{A P}]_{0}$ increases from 0.5 to 4 M (Figure 9e). Replotting the $k_{\mathrm{obs}}$ values versus the reciprocal of $[\mathbf{A P}]_{0}$ established a reasonable linearity with a correlation coefficient of 0.987 (Figure 9f). The -1 st-order dependence on $[\mathbf{A P}]_{0}$ is consistent with eq 2 . The rates observed with $[\mathbf{A P}]_{0}$ at 3 and 4 M were rather slower than those expected from the $0.5-2 \mathrm{M}$ data. This deviation is probably due to changes in the properties of the solvent, which comprises $i \mathrm{PrOH}$ and AP in a $2: 1$ to $1: 1$ ratio, because the characteristics of AP exert a significant effect on the polarity and dielectronic constant of the solvent system. ${ }^{23 \mathrm{~d}}$ In all cases, the high enantioselectivity was maintained with $[\mathbf{A}]_{0},[\mathbf{L}]_{0}, p H_{2}$, and $[\mathbf{A P}]_{0}$ varied (Figure 9, red squares).

Equation 2 can therefore be rewritten as eq 3 .

$$
\begin{align*}
& {[\mathbf{P E}]=\left(k_{0} k_{2}[\mathbf{A}]_{0}\left[H_{2}\right]^{3} / 2\left(K_{\mathrm{AP}}[\mathbf{A P}]_{0}+K_{i \mathrm{PrOH}}[i \mathrm{PrOH}]+1\right)\right) t^{2}} \\
& \quad=k_{\mathrm{obs}} t^{2} \tag{3}
\end{align*}
$$

2.6. Inhibitory Effect. Equation 3 applies only in the early stages of the reaction; therefore, no [PE] term is included. Inhibition of the catalytic activity, however, should be related to all possible QH species, including substrate AP , product PE , and solvent $i \mathrm{PrOH}$, in the equilibrium $\mathbf{D}+\mathrm{QH} \rightleftarrows \mathrm{E}_{\mathrm{QH}}$ with $K_{\mathrm{QH}}$ in Figure 8. Formation of the Ru enolate and alkoxide as $\mathrm{E}_{\mathrm{QH}}$ is the most probable inhibitory process, ${ }^{21 f, 23 c}$ and the order of the inhibitory effect is thought to be AP $>\mathbf{P E}>i \mathrm{PrOH}$ based on the $\mathrm{pKa}\left(\mathrm{H}_{2} \mathrm{O}\right)$ values (AP enol (10.34), ${ }^{30} \mathrm{PE}$ (15.4), ${ }^{31}$ and $i \mathrm{PrOH}(16.5)^{32}$ ). The inhibitory factor is not simple, being affected not only by acid and base principles but also by the concentration, steric and electronic properties of $\mathrm{E}_{\mathrm{QH}}$, and the emergence of other reaction pathways specific to $\mathrm{E}_{\mathrm{QH}}$.

Figure 10. Comparison of the inhibitory effect of acetophenone (AP), cyclohexyl methyl ketone (CMK), and 2,2-dimethylpropiophenone (DMPP) under the standard conditions $\left([(R)-\mathrm{Ph}-\mathrm{BINAN}-\mathrm{H}-\mathrm{Py}((R)-\mathrm{L})]_{0}=\left[\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\operatorname{cod})(\mathrm{A})\right]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM}, 50 \mathrm{~atm} \mathrm{H}_{2}, i \mathrm{PrOH}\right.$, $25{ }^{\circ} \mathrm{C}$ ). (a) Reciprocal plot of $k_{\text {obs }}$ versus $[\mathbf{A P}]_{0}$. (b) Reciprocal plot of $k_{\text {obs }}$ versus [CMK $]_{0}$. (c) Reciprocal plot of $k_{\text {obs }}$ versus $[\mathbf{D M P P}]_{0}$. In (a), (b), and (c), the slope corresponds to $2\left(K_{\mathrm{QH}}[\mathbf{Q H}]_{0}+K_{i \mathrm{PrOH}}[i \mathrm{PrOH}]+1\right) / k_{0} k_{2}[\mathbf{A}]_{0}\left[\mathrm{H}_{2}\right]^{3}(\mathbf{Q H}=\mathbf{A P}, \mathbf{C M K}$, or $\mathbf{D M P P})$. Because the value of the denominator is constant under a given condition, a steeper slope means greater inhibition.

To make a qualitative interpretation of the inhibitory effect, the following experiments were carried out by using AP, cyclohexyl methyl ketone (CMK), 2,2-dimethylpropiophenone (DMPP), (R)-PE, and (S)-PE: CMK is enolizable but lacks the benzene ring of AP, whereas DMPP is not enolizable but has a benzene ring. ( $R$ )-PE is the major product of $(R)-\mathrm{L} / \mathrm{A}$ catalyzed asymmetric hydrogenation, while ( $S$ )-PE is the minor enantiomeric product. In comparing inhibition among AP, CMK, and DMPP, however, care must be taken because these ketones are completely different both sterically and electronically and vary in reactivity and selectivity in the ( $R$ )-L/Acatalyzed asymmetric hydrogenation: namely, 94:6 er and $k_{\text {obs }}=$ $2.50 \times 10^{-2} \mathrm{M} \mathrm{h}^{-2}$ for AP; 42:58 er and $k_{\text {obs }}=8.31 \times 10^{-2} \mathrm{M}$ $\mathrm{h}^{-2}$ for CMK; and 93:7 er and $k_{\text {obs }}=1.67 \times 10^{-2} \mathrm{M} \mathrm{h}^{-2}$ for DMPP at a substrate concentration of 1 M . Bearing this in mind, and with the assumption that the same mechanism is operating as for AP, the inhibitory effect was investigated as discussed below.
2.6.1. Ketone Substrates: AP, CMK, and DMPP. To analyze the inhibitory effect of ketone substrates and $i \mathrm{PrOH}$, eq 3 was converted to eq 4.

$$
\begin{align*}
1 / k_{\mathrm{obs}}= & 2\left(K_{\mathrm{AP}}[\mathbf{A P}]_{0}+K_{i \mathrm{PrOH}}[i \mathrm{PrOH}]+1\right) \\
& / k_{0} k_{2}[\mathbf{A}]_{0}\left[\mathrm{H}_{2}\right]^{3} \tag{4}
\end{align*}
$$

The plots of $1 / k_{\text {obs }}$ versus $[\mathbf{A P}]_{0}$ gave a straight line with a small $y$-intercept value ( -4.98 ) within the range of $0.5-2 \mathrm{M}$ (Figure 10a). The direct proportion from the origin shows that (i) AP is the major inhibitor of the formation of $\mathbf{D}$; (ii) the $\mathbf{D}$ $\rightleftarrows \mathbf{E}_{\mathrm{AP}}$ equilibrium point lies toward the far $\mathbf{E}_{\mathrm{AP}}$ side $(1 \ll$ $K_{\mathrm{AP}}$ ); and (iii) inhibition by $i \mathrm{PrOH}$ is negligible ( $\mathrm{K}_{\text {iPrOH }} \ll$ $\left.K_{\mathrm{AP}}\right)$. The inhibition profile of CMK also showed the same tendency as that of AP (Figure 10b), albeit with a 4.5 -fold shallower slope than AP ( 47.5 vs 10.5). We assume that this difference may originate from $\mathrm{CH}-\pi$ stabilization of $\mathrm{E}_{\mathrm{AP}}$, whereby the $\mathrm{C}_{6} \mathrm{H}_{5} \pi$ system interacts with the $\mathrm{PyC}(6) \mathrm{H}$ of the Ph-BINAN-H-Py ligand. The extra inhibitory factor exists only for AP and not for CMK, reflecting the lower reactivity of AP $\left(k_{\mathrm{obs}}=2.50 \times 10^{-2} \mathrm{M} \mathrm{h}^{-2}\right.$ for $[\mathbf{A P}]_{0}=1 \mathrm{M} ; k_{\mathrm{obs}}=8.31 \times 10^{-2}$ $\mathrm{M} \mathrm{h}^{-2}$ for $\left.[\mathrm{CMK}]_{0}=1 \mathrm{M}\right)$. By contrast, DMPP, which has no proton, gave a straight line with a shallow slope (20.4) and a large $y$-intercept $(+39.7)$ as shown in Figure 10c. This profile can be understood by assuming that nonenolizable DMPP relatively enhances the degree of the $i \mathrm{PrOH}$ inhibitory effect toward the catalytic cycle via a 16e Ru amide D. Nonetheless,
because DMPP causes little inhibition in the present catalysis, it shows less reactivity than $\mathbf{A P}\left(k_{\text {obs }}=1.67 \times 10^{-2}\right.$ vs $2.50 \times 10^{-2}$ $\mathrm{M} \mathrm{h}^{-2}$ ). A steric effect of DMPP would be the reason.

This series of experiments indicates that the inhibition resulting from AP and CMK would be caused mainly by formation of the $\mathrm{Ru} O$-enolate ${ }^{21 f, 33}$ and partly by the phenyl group of AP. In addition, the reaction of AP at 1 M was not inhibited by the addition of ethylbenzene in the range of $1-2$ M under the standard conditions. ${ }^{20}$ This result supports the idea that the major inhibitory factor of AP originates from formation of the CH - $\pi$-stabilized $\mathrm{Ru} O$-enolate $\mathrm{E}_{\mathrm{AP}}$ and not from the arene- Ru complex.
2.6.2. Enantiomeric Products: (R)-PE and (S)-PE. To evaluate the inhibitory effect of PE quantitatively, reaction rates were determined for the hydrogenation of AP ( 0.5 M ) under the standard conditions except for the presence of 0.5 and 1 M PE . By defining the externally added ( $R$ )-PE and ( $S$ )$\mathbf{P E}$ as $(R)-\mathrm{PE}_{\text {ex }}$ and $(S)-\mathrm{PE}_{\text {ex }}$ respectively, eq 5 can be deduced. ${ }^{20}$

$$
\begin{align*}
1 / k_{\mathrm{obs}}= & 2\left(K_{\mathbf{A P}}[\mathbf{A P}]_{0}+K_{(R)-\mathbf{P E}}\left[(R)-\mathbf{P E}_{\mathbf{e x}}\right]\right. \\
& \left.+K_{(S)-\mathbf{P E}}\left[(S)-\mathbf{P E}_{\mathbf{e x}}\right]+K_{i \mathrm{PrOH}}[i \operatorname{PrOH}]+1\right) \\
& / k_{0} k_{2}[\mathbf{A}]_{0}\left[\mathrm{H}_{2}\right]^{3} \tag{5}
\end{align*}
$$

Because $1 / k_{\text {obs }}$ shows a linear relation to both $\left[(R)-\mathrm{PE}_{\mathrm{ex}}\right]$ and $\left[(S)-\mathrm{PE}_{\mathrm{ex}}\right]$ in eq 5 , the slope in the plots of $1 / k_{\text {obs }}$ against $\left[\mathrm{PE}_{\mathbf{e x}}\right]$ indicates the degree of the inhibitory effect. As shown in Figure 11a, the product ( $R$ )-PE, which is generated from ( $R$ )L/A catalysis, had little effect on the reactivity, giving a shallow slope. By contrast, the enantiomeric product ( $S$ )-PE, which is the minor product in the present $R$ catalysis, significantly inhibited the reaction. The $K_{(S) \text {-PE }} / K_{(R) \text {-PE }}$ ratio approached 15 (slope ratio $=176 / 12$ ). The 15 -fold difference in the equilibrium constant may be due to a CH- $\pi$ interaction between the phenyl group of $(S)$-PE alkoxide and $\operatorname{PyC}(6) \mathrm{H}$ of $(R)$-L, which would stabilize $\mathbf{E}_{(S) \text {-PE }} \cdot{ }^{34}$ The conformer with such a $\mathrm{CH}-\pi$ interaction in the corresponding $\mathrm{Ru}-(R)$ - PE alkoxide $\left(\mathbf{E}_{(R) \text {-PE }}\right)$ would be energetically unfavored for steric reasons. The methyl group is forced into a location in the crowded region (see Figure 11, upper structure). These results imply that chiral amplification may occur in the present asymmetric hydrogenation via a new mechanism. ${ }^{7 b, 35}$
2.7. Simulation. A series of kinetic studies revealed that the present asymmetric hydrogenation of AP proceeds without

Figure 11. Quantitative analysis of the inhibitory effect of $(R)-1-$ phenylethanol $((R)-\mathrm{PE})$ and $(S)-\mathrm{PE}$, and possible structures of the Ru alkoxides, $\mathbf{E}_{(R)-\mathrm{PE}}$ and $\mathbf{E}_{(S) \text {-PE }}$. (a) Reciprocal plot of $k_{\mathrm{obs}}$ versus $[(R)$ $\mathbf{P E}_{\mathrm{ex}}$ ]. (b) Reciprocal plot of $k_{\text {obs }}$ versus [(S)-PE $\mathrm{ex}_{\mathrm{ex}}$ ]. Hydrogenation of AP $(0.5 \mathrm{M})$ was carried out in the absence and presence of PE ( 0.5 and 1 M$)$ under the standard conditions $([(R)$-Ph-BINAN-H-Py $((R)-$ $\mathbf{L})]_{0}=\left[\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}(\operatorname{cod})(\mathbf{A})\right]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM}, 50$ atm $\left.\mathrm{H}_{2}, i \mathrm{PrOH}, 25^{\circ} \mathrm{C}\right)$. The red arrow indicates a steric repulsion.
significant inhibition from the solvent $i \mathrm{PrOH}$ and the major product ( $R$ )-PE; therefore, the kinetic profile shown in Figure 8 can be expressed by eq 6 in the early stages of the reaction under the standard conditions.

$$
\begin{equation*}
[\mathbf{P E}]=k_{\mathrm{obs}} t^{2}=k_{0} k_{2}[\mathbf{A}]_{0}\left[\mathrm{H}_{2}\right]^{3} t^{2} / 2 \mathrm{~K}_{\mathbf{A P}}[\mathbf{A P}]_{0} \tag{6}
\end{equation*}
$$

To confirm its validity, eq 6 was used to simulate the relationships between time and PE concentration, which were then compared with the $t /[\mathrm{PE}]$ curves observed under different conditions of $[\mathbf{A}]_{0}$, pressure $p \mathrm{H}_{2}$, or $[\mathbf{A P}]_{0}$. The $k_{\mathrm{obs}}$ values obtained under the conditions of $[\mathbf{A}]_{0}=1-4 \mathrm{mM}, \mathrm{pH} \mathrm{H}_{2}=25-$ 90 atm , and $[\mathbf{A P}]_{0}=0.5-2 \mathrm{M}$ (Figure 9a, c, and e) gave $k_{0} k_{2} /$ $K_{\mathrm{AP}}=4.1 \times 10^{3} \mathrm{M}^{-2} \mathrm{~h}^{-2}$ as the average value. ${ }^{36}$ This value was substituted into eq 6 to simulate the $t /[\mathrm{PE}]$ relationship (Figure 12a-c). Close agreement between the simulated (blue surfaces) and experimental (red lines) curves confirmed that
the hydrogenation proceeds according to eq 6 with a $k_{0} k_{2} / K_{\mathrm{AP}}$ value of $4.1 \times 10^{3} \mathrm{M}^{-2} \mathrm{~h}^{-2}$ in the early stages.
2.8. Effect of $[\mathrm{L}]_{0}$ and [tBuOK]. As shown in Figure 9b, the initial concentration of $(R)$ - L in the range of $0.1-4 \mathrm{mM}$ has little effect on the rate. Therefore, even a reaction with a smaller amount of $\mathbf{L}$ than $\mathbf{A}\left([\mathbf{L}]_{0}=0.5 \mathrm{mM} ;[\mathbf{A}]_{0}=2 \mathrm{mM} ; \mathbf{L} / \mathbf{A}=1 /\right.$ 4) showed essentially the same reactivity and selectivity as that with an $\mathbf{L} / \mathbf{A}$ ratio of $1: 1$. Moreover, a further decrease in the $\mathbf{L} /$ A ratio to $1 / 20\left([\mathbf{L}]_{0}=0.1 \mathrm{mM} ;[\mathbf{A}]_{0}=2 \mathrm{mM}\right)$ produced $\mathbf{P E}$ in an $R / S$ er of $96: 4$ without a significant loss of reactivity. As shown in Figure 13, an even further decrease in the L/A ratio

Figure 13. Time-product concentration curves obtained with an extremely low concentration of $(R)-\mathbf{L}\left([\mathbf{L}]_{0}=0.02 \mathrm{mM}\right.$ and 0.05 mM , $\left.[\mathbf{A}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM},[\mathrm{AP}]_{0}=2 \mathrm{M}, 50 \mathrm{~atm} \mathrm{H}_{2}\right)$.
to $1 / 40\left([\mathbf{L}]_{0}=0.05 \mathrm{mM} ;[\mathbf{A}]_{0}=2 \mathrm{mM}\right)$ led to a straight line in terms of the $t /[\mathrm{PE}]$ relationship to the point of the reaction completion, giving $(R)$-PE with a 94:6 er. In the L/A ratio of $1 /$ $100\left([\mathbf{L}]_{0}=0.02 \mathrm{mM}\right.$ and $\left.[\mathbf{A}]_{0}=2 \mathrm{mM}\right)$, the straight-line phenomenon was observed. Although the enantioselectivity decreased to $87: 13$, the degree of chiral multiplication approached 87000 . Under these conditions, the $t /[\mathrm{PE}]$ curve no longer follows the time-squared equation $\left([\mathrm{PE}]=k_{\mathrm{obs}}{ }^{2}\right)$. At such an extremely low concentration of $\mathbf{L}$, all Ph-BINAN-H-Py molecules would be used to generate B. Consistent with this view, the rate of $[\mathbf{L}]_{0}=0.02 \mathrm{mM}$ was proportionally slowed to $2 / 5$ that of $[\mathbf{L}]_{0}=0.05 \mathrm{mM}\left(0.0271\right.$ vs $\left.0.0743 \mathrm{M} \mathrm{h}^{-1}\right)$. The rate of $0.26 \mathrm{M} \mathrm{h}^{-1}$ in the later stages under the standard conditions (Figure 7a) determines the approximate concentration of $R \mathrm{Ru}_{\text {cycle }}$ to be $0.1-0.2 \mathrm{mM}$, supporting the fact that the rate is essentially not affected by $[\mathbf{L}]_{0}>0.1 \mathrm{mM}$ (Figure 9 b ).

Within the range of $1-20 \mathrm{mM}$, the initial concentration of $t \mathrm{BuOK}$ was also not influential on the rate and enantioselectivity (Figure 14a). A concentration of $t \mathrm{BuOK}(1 \mathrm{mM})$ that was $50 \%$ lower than that of the $\mathrm{Ru} \pi$-allyl precursor $\mathrm{A}(2 \mathrm{mM})$

Figure 12. Simulation (blue surfaces) and observation (red lines) of the $t /[\mathrm{PE}]$ relationship from $0 \%$ to $30 \%$ conversion in the (R)-L/A-catalyzed hydrogenation of AP in $i \mathrm{PrOH}$ at $25^{\circ} \mathrm{C}$. (a) $t /[\mathrm{PE}]$ relationship as a function of $[\mathbf{A}]_{0}\left([(R)-\mathrm{L}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM} ;[\mathbf{A}]_{0}=1,2\right.$, and $4 \mathrm{mM} ;[\mathbf{A P}]_{0}$ $\left.=2 \mathrm{M} ; 50 \mathrm{~atm} \mathrm{H}_{2}\right)$. (b) $t /[\mathrm{PE}]$ relationship as a function of $p \mathrm{H}_{2}\left([(R)-\mathrm{L}]_{0}=[\mathbf{A}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM} ;[\mathbf{A P}]_{0}=2 \mathrm{M} ; 25,50,70\right.$, and $\left.90 \mathrm{~atm} \mathrm{H}_{2}\right)$. (c) $t /[\mathbf{P E}]$ relationship as a function of $[\mathbf{A P}]_{0}\left([(R)-\mathbf{L}]_{0}=[\mathbf{A}]_{0}=[t \mathrm{BuOK}]=2 \mathrm{mM} ;[\mathbf{A P}]_{0}=0.5\right.$, 1 , and $\left.2 \mathrm{M} ; 50 \mathrm{~atm} \mathrm{H}_{2}\right)$. Simulation conditions: $[\mathrm{PE}]$ $=k_{0} k_{2}[\mathbf{A}]_{0}\left[\mathrm{H}_{2}\right]^{3} t^{2} / 2 \mathrm{~K}_{\mathrm{AP}}[\mathrm{AP}]_{0}$ with $k_{0} k_{2} / K_{\mathrm{AP}}=4.1 \times 10^{3} \mathrm{M}^{-2} \mathrm{~h}^{-2}$.

Figure 14. (a) Plot of $k_{\text {obs }}$ as a function of $[t \mathrm{BuOK}]$ from 0.5 to $20 \mathrm{mM}\left([\mathbf{A}]_{0}=[(R)-\mathbf{L}]_{0}=2 \mathrm{mM},[\mathbf{A P}]_{0}=2 \mathrm{M}, 50 \mathrm{~atm} \mathrm{H}_{2}\right)$. (b) Time-product concentration curves obtained without $\mathrm{BuOK}\left([\mathrm{BuOK}]=0 \mathrm{mM} ;[\mathbf{L}]_{0}=2 \mathrm{mM} ;[\mathbf{A}]_{0}=1,1.5,2\right.$, and $\left.4 \mathrm{mM} ;[\mathbf{A P}]_{0}=2 \mathrm{M} ; 50 \mathrm{~atm} \mathrm{H},{ }_{2}\right)$. (c) Plot of $[\mathrm{PE}]$ as a function of $t^{3}$ of graph (b).
was enough to maintain reactivity. When $[t \mathrm{BuOK}]$ was decreased to 0.5 mM , the reactivity was halved ( $k_{\mathrm{obs}}=1.17 \times$ $10^{-2}$ vs $6.89 \times 10^{-3} \mathrm{M} \mathrm{h}^{-2}$ ). Furthermore, as shown in Figure 14 b , even in the absence of $t \mathrm{BuOK}\left([\mathrm{A}]_{0}=1,1.5,2\right.$, and 4 mM ), the reaction went to completion, although the rate was extremely slow in the early stages. Replotting the $t /[\mathrm{PE}]$ relation in Figure 14b as a function of $t^{3}$ exhibited a reasonably linear relationship (Figure 14c), although the $t^{3} /[\mathrm{PE}]$ curve obtained with $[\mathbf{A}]_{0}=1 \mathrm{mM}$ deviated from the ideal one. The change in the order of $t$ from second to third in the absence of $[t \mathrm{BuOK}]$ implies that the ever-changing species $\left[\mathrm{Ru}_{\text {cycle }}\right]$, $[\mathrm{AP}]$, and $[\mathrm{PE}]$ are involved in this cycle in a different way than when [ tBuOK ] is present under the standard conditions. The slopes of the linear lines in the $t^{3} /[\mathrm{PE}]$ plotting (blue lines) have a second-order dependence on $[\mathbf{A}]_{0}$. So, when $[\mathbf{A}]_{0}$ is increased from 1 to 1.5 mM , the slope is steeper by a factor of $(1.5 / 1)^{2}=$ 2.25, which is close to the observed value, $\left(0.80 \times 10^{-4}\right) /(0.40$ $\left.\times 10^{-4}\right)=2$. The second-order dependence on $[\mathbf{A}]_{0}$ can be also observed when 1.5 mM is increased to $2 \mathrm{mM}\left((2 / 1.5)^{2}=1.78\right.$ vs $\left.\left(1.52 \times 10^{-4}\right) /\left(0.80 \times 10^{-4}\right)=1.9\right)$, and when $2 \mathrm{mM}=>4$ $\mathrm{mM}\left((4 / 2)^{2}=4\right.$ vs $\left.\left(6.84 \times 10^{-4}\right) /\left(1.52 \times 10^{-4}\right)=4.5\right)$. One possible explanation is that two $\mathrm{Ru}_{\text {cycle }}$ molecules are involved in the catalytic cycle established in the absence of $t \mathrm{BuOK}$. One $R \mathrm{u}_{\text {cycle }}$ species may act as a base instead of $t \mathrm{BuOK}$. $\left[\mathrm{Ru}_{\text {cycle }}\right]$ increases with a first-order time dependence; as a result, the involvement of another $\mathrm{Ru}_{\text {cycle }}$ in the cycle would alter [PE] = $k_{\text {obs }} t^{2}$ to $[\mathrm{PE}]=k_{\text {obs }} t^{3}$. The inclusion of at least $1 \mathrm{mM} t \mathrm{BuOK}$ might prevent the aggregation of intermediary Ru species leading to $\mathbf{B}$, or it might enhance the reactivity of $\mathbf{A}$ toward $\mathrm{H}_{2}$, thereby initiating the reaction without an induction period.
2.9. Enantioface Selection. Figure 15 shows the $\mathbf{B}+\mathbf{A P}$ $->\mathbf{D}+\mathbf{P E}$ step in detail. We believe that the reaction proceeds via the prior formation of an $\mathrm{N}-\mathrm{H}--\mathrm{O}=\mathrm{C}$ hydrogen bond between $\mathbf{B}$ and AP. A clockwise rotation ${ }^{37}$ of the $\mathrm{C}=\mathrm{O}$ axis forms the transition state $\mathbf{C}_{S i}$, in which the Si face of the electrophilic $\mathrm{C}=\mathrm{O}$ group is facing the nucleophilic Ru hydrogen atom. An anticlockwise rotation ${ }^{37}$ gives $\mathrm{C}_{R e}$ the structure of which is sterically more favored than that of $\mathbf{C}_{S i}$. Nevertheless, $\mathbf{C}_{S i}$ is more favored than $\mathbf{C}_{R e}$, resulting in the production of ( $R$ )-PE as the major product. This sense of enantioselectivity holds for various aromatic ketones. ${ }^{13}$ An attractive interaction is expected to stabilize the $\mathbf{C}_{S i}$ transition state: possible candidates would be (i) a $\mathrm{CH}-\pi$ interaction between $\mathrm{PyC}(6) \mathrm{H}$ and the aromatic $\pi$ system of AP (factor I) and (ii) a CH- $\pi$ interaction between ortho-HPh of AP and the $\mathrm{C}(3)-\mathrm{C}\left(3^{\prime}\right)-\mathrm{Ph} \pi$ system of ( $R$ )-L (factor II).
2.9.1. Hammett Analysis. To determine which of these factors is involved, we examined the enantioselectivity of AP

Figure 15. Proposed mechanism of enantioselection in the $(R)-\mathrm{Ph}-$ BINAN-H-Py- $\mathrm{RuH}_{2}$-catalyzed hydrogenation of AP.
possessing a different ring substituent X at the para position, including $\mathrm{CH}_{3} \mathrm{O}, \mathrm{CH}_{3}$, and $\mathrm{CF}_{3} .{ }^{20}$ All of the reactions were completed within 18 h under the standard conditions. The presence of an electron-donating substituent tended to increase the enantioselectivity, which ranged from an $R / S$ er of 90:10 $\left(4-\mathrm{CF}_{3}\right)$ to an $R / S$ er of $99: 1\left(4-\mathrm{CH}_{3} \mathrm{O}\right)$. The Hammett plot of $\ln (R / S)$ versus the standard $\sigma$ constants for the substituent parameter exhibited a reasonably linear relationship (Figure 16a), indicating that a single reactive mechanism is operating in the asymmetric hydrogenation with the involvement of factor I. By contrast, the enantioselectivity with ( $R$ )-Ph-BINAN-H-Py ligands possessing a substituent Y at the para position of the $\mathrm{C}(3)-\mathrm{C}\left(3^{\prime}\right)$-phenyl group virtually remained unchanged ( $R / S$ er $=96: 4-97: 3)$ (Figure 16b). Overall, the transition state $\mathrm{C}_{S i}$ is most likely to be stabilized by factor I: namely, a CH- $\pi$ interaction between $\operatorname{PyC}(6) \mathrm{H}$ and the aromatic $\pi$ system of AP. This is the origin of the enantioselectivity in the ( $R$ )-L/Acatalyzed hydrogenation of AP giving ( $R$ )-PE.
2.9.2. ${ }^{12} \mathrm{C} /{ }^{13} \mathrm{C}$ Kinetic Isotope Effect. In this $\mathbf{B} \rightarrow \mathbf{D}$ step, the hydrogen bond formation between $\mathbf{B}$ and $\mathbf{A P}$ would have no energy barrier, and the rate would be determined by the hydride transfer step via $\mathbf{C}_{S i}$, where the blue-colored hydrogen atom on Ru and the red-colored hydrogen atom on $\mathrm{sp}^{3} \mathrm{~N}$ are delivered to the $\mathrm{C}=\mathrm{O}$ bond in a concerted manner (see Figure

Figure 16. Hammett plots of $\ln ([(R)-\mathrm{PE}] /[(S)-\mathrm{PE}])$ as a function of standard $\sigma$ constants. (a) Effect of substituent X at the para position of AP on enantioselectivity. (b) Effect of substituent $Y$ at the para position of the Ph group of $(R)-\mathrm{Ph}-\mathrm{BINAN}-\mathrm{H}-\mathrm{Py}$ on enantioselectivity.
15). Direct attack of RuH on $\mathrm{C}=\mathrm{O}$ without formation of an $\mathrm{sp}^{3} \mathrm{~N}-\mathrm{H}--\mathrm{O}=\mathrm{C}$ hydrogen bond is the most unlikely possibility.

To confirm the occurrence of Intramol-DACat-based hydride transfer, the ${ }^{12} \mathrm{C} /{ }^{13} \mathrm{C}$ isotope effect was measured. ${ }^{20}$ The catalytic hydrogenation of AP was conducted on a 50 mmol scale under the standard conditions, and the reaction was stopped at $93 \%$ conversion ( 13 h ). The reaction mixture was concentrated and subjected to silica gel column chromatography, which gave PE with an $R / S$ er of $97: 3$ and $\mathbf{A P}(421 \mathrm{mg})$ in $6.9 \%$ yield. The recovered AP was subjected to ${ }^{13} \mathrm{C}$ NMR measurement, whereby the ${ }^{13} \mathrm{C}$ signal intensities were compared by using the ${ }^{13} \mathrm{C}$ signal at $\mathrm{C}_{\text {para }}$ of the phenyl group of AP (not involved in the reaction) as an internal standard. The relative proportion of the ${ }^{13} \mathrm{C}$ isotopic composition at $\mathrm{C}(1)=\mathrm{O}$ was increased by $8.4 \%$ (Figure 17a). No other signals showed significant changes in ${ }^{13} \mathrm{C}$

Figure 17. Measurement of the ${ }^{12} \mathrm{C} /{ }^{13} \mathrm{C}$ isotope effect in acetophenone (AP) recovered in $6.9 \%$ yield after $93 \%$ conversion to PE under the standard conditions. (a) ${ }^{13} \mathrm{C}$ isotopic composition determined by ${ }^{13} \mathrm{C}$ NMR analysis. (b) ${ }^{12} \mathrm{C} /{ }^{13} \mathrm{C}$ kinetic isotope effect calculated by using $\mathrm{C}_{\text {para }}$ as a standard.
isotopic composition. Using the equations of Singleton and Thomas, ${ }^{38}$ the ${ }^{12} \mathrm{C} /{ }^{13} \mathrm{C}$ isotope effect was calculated to be 1.031 (Figure 17b). This observation of the ${ }^{12} \mathrm{C} /{ }^{13} \mathrm{C}$ isotope effect at $\mathrm{C}(1)$ is consistent with the Intramol-DACat mechanism. In addition, the lack of an isotope effect at $\mathrm{C}(2) \mathrm{H}_{3}$ of $\mathbf{A P}$ argues against the involvement of hydrogenation of the AP enol.
2.9.3. $\mathrm{N}-\mathrm{H}-\mathrm{-} \mathrm{O}=\mathrm{C}$ Hydrogen Bond. The molecular structure of $\Lambda$-cis- $\alpha-\mathrm{Ru}\left(\mathrm{OCOCH}_{3}\right)_{2}((\mathrm{R})-\mathrm{L})$ (2) in crystal (Figure 4 b ) suggests the existence of an $\mathrm{sp}^{3} \mathrm{~N}-\mathrm{H}--\mathrm{O}=\mathrm{C}$ hydrogen bond. The H---O length is considered to be 2.067$2.112 \AA$, as judged by the theoretical location of H on N (see top view). In addition, the dihedral angle made by $\mathrm{CH}_{3} \mathrm{COO}-$ $\mathrm{Ru}-\mathrm{N}-\mathrm{H}$ is $17.93^{\circ}$. The hydrogen bond, as well as the small dihedral angle, would also be reflected in the B/AP complex, effecting Intramol-DACat ability to transfer the two hydrogen atoms to the $\mathrm{C}=\mathrm{O}$ double bond of AP via $\mathrm{C}_{S i}$.
2.10. Hydrogenation versus Transfer Hydrogenation. The present asymmetric reduction was proved to proceed via

hydrogenation but not via transfer hydrogenation from $i \mathrm{PrOH}$ as follows. ${ }^{20,23 c, d}$ Under the standard conditions using $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CDOH}$ instead of $i \mathrm{PrOH},(R)$-PE and (S)-PE were quantitatively obtained in a 94:6 ratio. After separation of the enantiomers, the degree of protium incorporation into ( $R$ )-PE and (S)-PE was determined by ${ }^{1} \mathrm{H}$ NMR analysis. The relative H signal intensities toward the $\mathrm{C}_{\text {para }}-\mathrm{H}$ signal of the phenyl group ranged from 0.990 to 1.007 (Figure 18). Within the error
(a)

(b)

Figure 18. Ratio of protium incorporation in (R)-1-phenylethanol ( $(R)-\mathrm{PE})$ (a) and (S)-PE (b) obtained under the standard conditions using $\mathrm{H}_{2} /\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CDOH}$ and $\mathrm{H}_{2} / \mathrm{PrOH}$, respectively (acetone- $d_{6}$ with $45^{\circ}$ pulse and $30-\mathrm{s}$ relaxation delay).
of the analysis, no $\mathbf{D}$ was introduced at any carbons of $(R)$-PE or (S)-PE, clearly indicating that a transfer hydrogenation mechanism was not involved in the ( $R$ )-L/A-catalyzed reduction. The most likely explanation is that the major and minor products, $(R)-\mathrm{PE}$ and $(S)-\mathrm{PE}$, are both produced by the same mechanism ${ }^{17}$ with an energy difference of $2.07 \mathrm{kcal} / \mathrm{mol}$ between $\mathrm{C}_{R e}$ and $\mathrm{C}_{S i}$.

## 3. CONCLUSION

The present asymmetric hydrogenation of acetophenone (AP) using a combined system of $(R)$-Ph-BINAN-H-Py $((R)-\mathrm{L})$ and $\mathrm{Ru}\left(\pi-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2}\right)_{2}$ (cod) (A) proceeds with virtually no change in $\mathbf{L}$ and $\mathbf{A}$, giving $(R)-\mathbf{P E}$ with an $R / S$ ratio of 97:3. ${ }^{13}$ The series of mechanistic studies described has revealed the complete picture of the catalysis, which follows the rate law of $[\mathbf{P E}]=k_{0} k_{2}[\mathbf{A}]_{0}\left[\mathrm{H}_{2}\right]^{3} t^{2} / 2 K_{\mathrm{AP}}[\mathbf{A P}]_{0}$ with $k_{0} k_{2} / K_{\mathrm{AP}}=4.1 \times 10^{3}$ $\mathrm{M}^{-2} \mathrm{~h}^{-2}$. The time-squared term relates to two processes occurring in parallel: namely, the preliminary step before the cycle and the cycle itself.

The detailed reaction sequence in the preliminary process is unclear. Most probably, the introductory step would initiate with very slow and irreversible hydrogenolysis of the Ru- $\pi$-allyl bonds of $\mathbf{A}$ with $2-\mathrm{mol}$ amounts of $\mathrm{H}_{2}$ molecules by generation of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{CH}_{2},{ }^{39}$ producing a tiny ( $<1 \%$ ) amount of an ambiguous $\mathrm{RuH}_{2}$ species in first-order for $[\mathbf{A}]_{0}$ and secondorder for $\left[\mathrm{H}_{2}\right]$. Immediately after its generation, the $\mathrm{RuH}_{2}$ species is trapped without any energy barrier by the particular tetradentate $\mathrm{sp}^{2} \mathrm{~N} / \mathrm{sp}^{3} \mathrm{NH}$ linear N 4 ligand (R)-L. The characteristics of $(R)$-L, including very strong metal capturing ability with a high level of cis- $\alpha$ selectivity in the formation of octahedral metal complexes, enable the generation of such a delicate $\Lambda$-cis- $\alpha \mathbf{B}$ intermediate, which works as a very reactive catalyst in the presence of AP but readily decomposes in its
absence. The first- and zeroth-order kinetics observed for $[\mathbf{A}]_{0}$ and $[\mathbf{L}]_{0}$, respectively, as well as the minimal effect of $[\mathbf{A}]_{0}$, $[\mathbf{L}]_{0}$, and $\left[\mathrm{H}_{2}\right]\left(p \mathrm{H}_{2}\right)$ on enantioselectivity, excludes the possibility of prior replacement of the cod ligand of $\mathbf{A}$ with ( $R$ )$\mathbf{L}$, followed by hydrogenolysis of the Ru- $\pi$-allyl bonds. In parallel to its reluctant generation, $\mathbf{B}$ rapidly converts AP to $\mathbf{P E}$ by means of another $\mathrm{H}_{2}$ molecule. In the $\mathbf{B} \rightarrow \mathbf{D}$ step, the NH in B quickly captures AP to move to a charge-alternating sixmembered transition state $\mathbf{C}_{S_{i}}$. Here, the two hydrogen atoms of the polarized $\mathrm{H}^{\delta+}-\mathrm{N}^{\delta-}--\mathrm{Ru}^{\delta+}-\mathrm{H}^{\delta-}$ moiety are delivered in a concerted manner to the similarly polarized $\mathrm{C}^{\delta+}=\mathrm{O}^{\delta-}$ of AP via the prior formation of an $\mathrm{N}-\mathrm{H}--\mathrm{O}=\mathrm{C}$ hydrogen bond, for which the energy barrier is lower than that for the subsequent hydride transfer. The Si face of AP is selected because of a CH$\pi$ attractive interaction between the $\operatorname{PyC}(6) \mathrm{H}$ of $\mathbf{L}$ and the aromatic $\pi$ system of AP. The electronic factor surpasses the steric advantage in $\mathbf{C}_{R e}$. The Intramol-DACat mechanism operates in $\mathrm{C}_{S i}$ to give the coordinatively unsaturated Ru amide D. This $\mathbf{B}->\mathbf{D}$ step proceeds with a zeroth-order dependence on $[\mathbf{A P}]$ in the reaction system, but the turnover rate is slowed mainly by the formation of a Ru enolate of AP, which is also stabilized by a $\mathrm{CH}-\pi$ attractive interaction. Inhibition from $i \mathrm{PrOH}$ and ( $R$ )-PE is negligible, but the degree of inhibition by the enantiomeric product ( $S$ )-PE is 15 times higher than that by ( $R$ )-PE.

The reaction frequency of the induction step is $<2.1 \times 10^{-4}$ $\mathrm{h}^{-1}$, while the turnover frequency of the cycle is $>5.7 \times 10^{4}$ $\mathrm{h}^{-1} .^{40}$ The eight-order difference in these frequencies causes the seemingly unusual phenomenon that PE is quantitatively produced without any detectable Ru complex formation. The $\mathbf{L} / \mathbf{A} / 2 \mathrm{H}_{2}$ to $\mathbf{B}$ process follows a first-order dependence on $[\mathbf{A}]_{0}$ and a zeroth-order dependence on $[\mathbf{L}]_{0}$; as a result, even a $1 /$ 100 ratio of $\mathbf{L}(0.02 \mathrm{mM})$ to $\mathbf{A}(2 \mathrm{mM})$ maintains high catalytic performance, attaining a chiral multiplication of 87000 .

There are likely to be many other examples in which a negligible amount of reactive and unstable species is operating in catalysis. ${ }^{41}$ The present study should stimulate our ideas for the further development of asymmetric molecular catalysis. By using preformed well-defined metal complexes, opportunities to find a high performance catalyst may sometimes be missed.

(33) For $\mathrm{Ru} O$-enolates and Rh O -enolates, see: ref 21b. (a) Hartwig, J. F.; Bergman, R. G.; Andersen, R. A. J. Am. Chem. Soc. 1990, 112, 3234-3236. (b) Slough, G. A.; Bergman, R. G.; Heathcock, C. H. J. Am. Chem. Soc. 1989, 111, 938-949. Regarding the possibility that the $\mathrm{Ru} C$-enolate is the inhibitory factor, see: ref 23 c .
(34) There may be an $\mathrm{NH}-\pi$ stabilization. For the related report, see: Sandoval, C. A.; Shi, Q.; Liu, S.; Noyori, R. Chem.-Asian J. 2009, 4, 1221-1224.
(35) Soai, K.; Shibata, T.; Morioka, H.; Choji, K. Nature 1995, 378, 767-768.
(36) The concentration of hydrogen was estimated to be 0.18 M at 50 atm of $\mathrm{pH}_{2}$; see Brunner, E. Ber. Bunsenges. Phys. Chem. 1979, 83, 715-721.
(37) Clockwise and anticlockwise mode is changed when the oxygen lone pair cis to aryl group is selected.
(38) Singleton, A. D.; Thomas, A. A. J. Am. Chem. Soc. 1995, 117, 9357-9358.
(39) Detection of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{CH}_{2}$ and cod was difficult because, at most, B was generated only $10 / 177 \mathrm{mM}$ under the ${ }^{1} \mathrm{H}$ NMR monitoring conditions (Figure 6).
(40) The $k_{0}$ value was assumed to be $6.46 \times 10^{-3} \mathrm{M}^{-2} \mathrm{~h}^{-1}$ at most, as estimated from the $\mathrm{S} / \mathrm{N}$ ratio of 177 observed in the ${ }^{1} \mathrm{H}$ NMR analysis (Figure 6b). By use of the values of $k_{0},\left[\mathrm{H}_{2}\right]=0.18 \mathrm{M},[\mathbf{A P}]_{0}=2 \mathrm{M}$, and $k_{0} k_{2} / K_{\mathrm{AP}}=4.1 \times 10^{3} \mathrm{M}^{-2} \mathrm{~h}^{-2}$, the frequency of the generation of $\mathbf{B}$ from $\mathbf{A}\left(v_{0} /[\mathbf{A}]_{0}=k_{0}\left[\mathrm{H}_{2}\right]^{2}\right)$ and the turnover frequency of $\mathbf{B}$ catalyzed hydrogenation $\left(v_{2} /\left[\mathrm{Ru}_{\text {cycle }}\right]=k_{2}\left[\mathrm{H}_{2}\right] / K_{\mathrm{AP}}[\mathbf{A P}]_{0}=\left(k_{0} k_{2} /\right.\right.$ $\left.\left.K_{\mathrm{AP}}\right)\left(1 / k_{0}\right)\left(\left[\mathrm{H}_{2}\right] /[\mathrm{AP}]_{0}\right)\right)$ are calculated to be $<2.1 \times 10^{-4}$ and $>5.7 \times$ $10^{4} \mathrm{~h}^{-1}$, respectively. Here, $v_{0}$ is defined as $-\mathrm{d}[\mathbf{A}] / \mathrm{d} t=k_{0}[\mathbf{A}]_{0}\left[\mathrm{H}_{2}\right]^{2}$, and $v_{2}$ is defined as $\mathrm{d}[\mathbf{P E}] / \mathrm{d} t=k_{2}\left[\mathrm{Ru}_{\text {cycle }}\right]\left[\mathrm{H}_{2}\right] / K_{\mathrm{AP}}[\mathbf{A P}]_{0}$.
