

is improved so as to require little bleaching. The fatty acid-ester content of the distillate is under positive control. Additional unusual design features are:

Two-stage pre-heating of the crude by steam recovered from condensate.

Distilled water for the "boiler-condenser" is assured by use of steam condensate.

Continuous distillation is possible.

Sweetwater is entirely eliminated.  
No closed distillate receivers are required.  
Separate concentration of distillates is eliminated.

## Computation Forms Relating to the Component Acid Analysis of Marine Animal Oils by the Ester Fractionation Method

W. S. RAPSON, MISS H. M. SCHWARTZ, R. H. STOY\* and N. J. VAN RENSBURG.\*\*

University of Cape Town, Cape Town, South Africa

In the ester fractionation procedure (1) for the component acid analysis of natural fats the compositions of the individual fractions are calculated from their determined saponification equivalents and iodine values. With marine animal oils in particular these calculations can be laborious and time-consuming, and we have found the elaboration of definite computation forms of very great assistance; once set up, they enable the compositions of most fractions to be calculated with the assistance of a computer. Moreover the use of such tables provides a concise and permanent record of the computations and greatly facilitates checking of calculations. In the present communication we therefore record such computation schemes as have been employed in recent component acid analyses of marine animal oils carried out in this laboratory (2). All have been arranged so as to make efficient use of tables of reciprocals, of multiplication tables such as those of Crelle (3), and of computing machines.

*Computations relating to fractions containing two saturated plus two unsaturated esters:*

The early "solid" and "liquid" ester fractions have been calculated to one or other of the following:

- (a)  $C_{12}$  and  $C_{14}$  saturated plus monoethenoid esters;
- (b)  $C_{14}$  and  $C_{16}$  saturated plus monoethenoid esters;
- (c)  $C_{16}$  and  $C_{18}$  saturated plus monoethenoid esters.

In calculating to these compositions, it has been customary in this laboratory to assume that the S.E. of the saturated portion of each fraction is the same as that of the whole fraction. This assumption leads to little error in the final analysis and does away with the necessity for isolating the saturated ester fraction. The compositions of such fractions may therefore be calculated from equations (1)-(3)

$$x + y + z = w \quad (1)$$

$$\frac{x}{E} + \frac{y}{E_1} + \frac{z}{E_2} = \frac{w}{E} \quad (2)$$

$$i_1 y + i_2 z = w i \quad (3)$$

where  $w$  = the weight of the fraction, whose S.E. =  $E$ , and I.V. =  $i$ .

$x$  = the weight of the saturated  $C_n$  plus  $C_{n+2}$  esters in the fraction, whose S.E.'s,  $E_3$  and  $E_4$  are equal to  $(E_1 + 2)$  and  $(E_2 + 2)$  respectively.

$y$  = the weight of  $C_n$  monoethenoid esters of S.E. =  $E_1$  and I.V. =  $i_1$  in the fraction.

$z$  = the weight of  $C_{n+2}$  monoethenoid esters of S.E. =  $E_2$  and I.V. =  $i_2$  in the fraction.

The solutions to these equations (1)-(3) are given in equations (4)-(6):

$$z = \frac{w i}{i_1} \cdot \frac{1}{Q + \frac{i_2}{i_1}} = \frac{w i}{i_1} \cdot \frac{1}{Q + \frac{E_1}{E_2}} \quad (4)$$

since both series of unsaturated esters are monoethenoid and therefore  $\frac{i_2}{i_1} = \frac{E_1}{E_2}$

$$y = Q \cdot z \quad (5)$$

$$x = w - (y + z) \quad (6)$$

$$\text{where } Q = \frac{E_1}{E_2} \cdot \frac{E_2 - E}{E - E_1}$$

The composition of the saturated ester fraction  $x$  may be calculated from the equations (7) and (8):

$$u + v = x \quad (7)$$

$$\frac{u}{E_3} + \frac{v}{E_4} = \frac{x}{E} \quad (8)$$

the solutions to which are

$$u = \frac{b - d}{c - d} \cdot x \quad (9)$$

$$\text{and } v = \frac{c - b}{c - d} \cdot x \quad (10)$$

where  $u$  = the weight of  $C_n$  esters of equivalent weight  $(E_1 + 2)$  present.

$v$  = the weight of  $C_{n+2}$  esters of equivalent weight  $(E_2 + 2)$  present.

$$c = \frac{1}{E_3} = \frac{1}{E_1 + 2}$$

$$d = \frac{1}{E_4} = \frac{1}{E_2 + 2}$$

$$b = \frac{1}{E}$$

\* From multiplication tables, or by use of a calculating machine.

\*\* From tables of reciprocals.

\*\*\* If accuracy is to be obtained in the evaluation of  $F_1-2a_1$  and  $F_2-2a_2$ , then the fractions combined for the purpose must not be too similar in composition. To illustrate this, fraction  $L_{117}$  which cannot be combined with  $L_{118}$  to give a significant result, has been combined with  $L_{116}$ , and the results are given in brackets.

\*\*\*\* Obtained directly from calculating machine, or else individual components can be written down from multiplication tables and summed.

The computation forms which have been used for calculating the compositions of early "solid" and "liquid" ester fractions, which are mixtures of  $C_{12}$  and  $C_{14}$  or  $C_{14}$  and  $C_{16}$  or  $C_{16}$  and  $C_{18}$  saturated and monoethenoid esters, are illustrated in Tables I(a)-I(e). Because of the frequency with which these three, and in particular the latter two, types of calculation are necessary, it has been found profitable to set up separate forms for each. It will be appreciated, however, that these three are not the only types of calculations of this kind which arise, and we have found that the compositions of individual higher solid ester fractions in particular must sometimes be calculated on the basis that they are mixtures of two saturated and two unsaturated esters. The unsaturated esters have then been assumed to possess the same average unsaturations as determined for them by the application of the Charnley method to the series of "liquid" ester fractions. The necessity for this assumption arises from the imperfection of the lead salt separation in the case of marine animal oils (2). Error must certainly be introduced into such calculations from this and from the earlier assumption that the S.E. of the saturated esters is the same as that of the whole fraction; since very few such fractions occur, the effect on the final analysis is not significant. Table II illustrates the generalised form of computation adopted in this type of calculation.

*Computations relating to "liquid" fractions containing  $C_{18}$  and higher unsaturated esters only:*

The evaluation of the compositions of fractions of the above types has been discussed in detail by Charnley (4). The composition of any such fraction is to be obtained from equations (11) and (12), viz.

$$1 + \frac{i}{12,690} - \frac{F_1}{E} = 28N_2 \quad (11)$$

$$\frac{1}{E} = N_1 + N_2 \quad (12)$$

where  $i$  = I.V. of the fraction.

$E$  = S.E. of the fraction.

$F_1$  = S.E. of saturated esters of the same carbon content ( $C_n$ ) as the lower molecular weight group of unsaturated esters present in the fraction.

$F_2$  = S.E. of saturated esters of the same carbon content ( $C_{n+2}$ ) as the higher molecular weight group of unsaturated esters present in the fraction.

$N_1$  = mols. of  $C_n$  unsaturated esters present in 1 gm. of the fraction.

$N_2$  = mols. of  $C_{n+2}$  unsaturated esters present, in 1 gm. of the fraction.

The weights of the components of such fraction are given by

$$x = N_1(F_1 - 2a_1)w \quad (13)$$

$$y = N_2(F_2 - 2a_2)w \quad (14)$$

where  $x$  = weight of  $C_n$  unsaturated esters of average unsaturation  $-2a_1H$  present.

$y$  = weight of  $C_{n+2}$  unsaturated esters of average unsaturation  $-2a_2H$  present.

$w$  = weight of the fraction.

$F_1 - 2a_1$  = S.E. of the  $C_n$  unsaturated esters present.

$F_2 - 2a_2$  = S.E. of the  $C_{n+2}$  unsaturated esters present.

The number of double bonds,  $a_1$  and  $a_2$ , are calculated from the values of  $N_1$  and  $N_2$  obtained in two

adjacent fractions, the relevant equations for the calculation being (15) and (16),

$$1 = (F_1 - 2a_1)N_1' + (F_2 - 2a_2)N_2' \quad (15)$$

$$1 = (F_1 - 2a_1)N_1'' + (F_2 - 2a_2)N_2'' \quad (16)$$

the solutions to which are

$$F_1 - 2a_1 = \frac{N_2' - N_2''}{N_1'' N_2' - N_1' N_2''} \quad (17)$$

$$F_2 - 2a_2 = \frac{N_1'' - N_1'}{N_1'' N_2' - N_1' N_2''} \quad (18)$$

A computation scheme for the evaluation of the compositions of fractions of this type is given in Table III. Data for a number of fractions are given in order to illustrate the variations in the values of  $(F_1 - 2a_1)$  and  $(F_2 - 2a_2)$  obtainable through the combination of different fractions in the Charnley method.

It is perhaps of interest to note that, from the effect of increasing unsaturation on boiling point (1), it might be expected that in any one series of fractions the degree of average unsaturation in each of the homologous groups of esters would fall as distillation proceeded. In practice (Table III) the results have not exhibited any definite trend but have shown a random scatter. This is probably a reflection of the experimental errors of the I.V. and S.E. determinations of individual fractions.

In practice the mean value for the average unsaturation has been used throughout. Calculation of such average unsaturation from the combination of as many pairs of different fractions as possible minimizes error in the final average and moreover gives an idea of the probable error in the final assessment of the degree of average unsaturation. Such a knowledge is valuable where a comparison of the average unsaturation of a given ester group in different oils is required (5).

*Computations relating to fractions containing one saturated and two unsaturated esters:*

Fractions of this type may occur in either "liquid" or "solid" series and their compositions are to be calculated from equations (19)-(21),

$$x + y + z = w \quad (19)$$

$$\frac{x}{E_s} + \frac{y}{E_1} + \frac{z}{E_2} = \frac{w}{E} \quad (20)$$

$$i_1 y + i_2 z = w i \quad (21)$$

in which

$w$  = the weight of the fraction of S.E. =  $E$ , and I.V. =  $i$ .

$x$  = the weight of saturated ester in the fraction, of S.E. =  $E_s$ .

$y$  = the weight of unsaturated ester in the fraction, of S.E. =  $E_1$ , and I.V. =  $i_1$ .

$z$  = the weight of unsaturated ester in the fraction, of S.E. =  $E_2$ , and I.V. =  $i_2$ .

The solutions to these equations are

$$y = \frac{wK_1}{K} \quad (22)$$

$$z = \frac{wK_2}{K} \quad (23)$$

$$x = w - (y + z) \quad (24)$$

$$\text{where } K = \frac{i_1(E_2 - E_3)}{E_2} - \frac{i_2(E_1 - E_3)}{E_1}$$

$$K_1 = \frac{i(E_2 - E_3)}{E_2} - \frac{i_2(E - E_3)}{E}$$

$$K_2 = \frac{i_1(E - E_3)}{E} - \frac{i(E_1 - E_3)}{E_1}$$

Computations relating to "liquid" ester fractions containing three unsaturated ester groups only:

Occasionally in the "liquid" ester series of fractions, when, for example, the  $C_{16}$  saturated esters have just distilled off, fractions are obtained whose composition can only be calculated on the basis that they contain three groups of unsaturated esters, e.g.  $C_{16}$ ,  $C_{18}$ , and  $C_{20}$  unsaturated esters. In such cases the composition of the fraction is to be evaluated from the equations (25), (26), and (27),

$$x + y + z = w \quad (25)$$

$$\frac{x}{E_1} + \frac{y}{E_2} + \frac{z}{E_3} = \frac{w}{E} \quad (26)$$

$$i_1x + i_2y + i_3z = wi \quad (27)$$

where  $w$  = the weight of the fraction, of S.E. =  $E$ , and I.V. =  $i$ .

$x$  = the weight of, say  $C_{16} - 2H$  esters present, of S.E. =  $E_1$  and I.V. =  $i_1$ .

$y$  = the weight of  $C_{18}$  unsaturated esters present, whose S.E. =  $E_2$ , and I.V. =  $i_2$ .

$z$  = the weight of  $C_{20}$  unsaturated esters present, whose S.E. =  $E_3$ , and I.V. =  $i_3$ .

The solutions to these equations are

$$x = \frac{D_1}{D_4}; y = \frac{D_2}{D_4}; z = \frac{D_3}{D_4}$$

$$\text{where } D_1 = w \left[ \frac{i_2 - i_3}{E} + \frac{i_3 - i}{E_2} + \frac{i - i_1}{E_3} \right] \quad (28)$$

$$D_2 = w \left[ \frac{i_1 - i}{E_3} + \frac{i - i_3}{E_1} + \frac{i_3 - i_1}{E} \right] \quad (29)$$

$$D_3 = w \left[ \frac{i_1 - i_2}{E} + \frac{i - i_1}{E_2} + \frac{i_2 - i}{E_1} \right] \quad (30)$$

$$D_4 = \frac{i_2 - i_1}{E_2} + \frac{i_1 - i_2}{E_3} + \frac{i_2 - i_3}{E_1} = \text{a constant } K \text{ for each set of fractions.} \quad (31)$$

In Table V is illustrated the form of computation developed for the calculation of the compositions of fractions of this type.

Computations of the composition of fractions on the basis of saponification equivalents alone:

The compositions of final fractions must often be assessed on the basis of S.E.'s. only, because oxidation and/or polymerisation reactions occur during distillation with the result that the iodine values of such fractions are often meaningless. In most analyses of marine animal oils the final "liquid" ester fraction has therefore been calculated to a mixture of  $C_{22}$  unsaturated esters (of known average S.E.) and  $C_{24}$  unsaturated esters, the average unsaturation of which has been taken as  $C_{24} - 10H$  in the absence of any method of determining the real value.

The equations for the calculations concerned are (7)-(10) and a convenient form of computation is that illustrated in columns 12-17 of Table II.

### Summary

Computation schemes have been found of assistance in calculations relating to the component acid analysis of marine animal oils by the ester fractionation method; these are described.
