## 353. The Dipole Moments and Structures of Some Quinoline Derivatives, and the Orientation of Claus and Hoffmann's x-Nitroisoquinoline.

By Catherine G. Le Fèvre and Raymond J. W. Le Fèvre.

In this section measurements of the dipole moments of a number of quinoline derivatives are recorded and discussed in relation to the possible influence of substitution upon the structure of the quinoline skeleton. Little relevant physical evidence is available in the literature.

Results.-The molecular polarisations and refractivities at infinite dilution in benzene solutions of quinoline and seven derivatives at $25^{\circ}$ are shown in Table I; from these data the dipole moment in each case (col. 4) has been calculated. The published values for the dipole moment (in Debye units here and throughout) of quinoline are : $2 \cdot 18$ (Le Fèvre and Smith, J., 1932, 2810) ; $2 \cdot 25$ (Rolinski, Physikal. Z., 1928, 29, 658) ; $2 \cdot 14$ (Bergmann, Engel, and Meyer, Ber., 1932, 65, 446) ; the present work supports the first value. The data for quinaldine are those of Rau and Narayanaswamy (Z. physikal. Chem., 1934, $B, \mathbf{2 6}, 23$ ).

Table I.

By treating the observed moments of the substituted quinolines as the vector sums of the moments of quinoline and its substituents, the former of which is known as to magnitude and the latter as to magnitude and direction (we have taken $\mathrm{Me}=0.37, \mathrm{NO}_{2}=4 \cdot 0$, and 2:4-dimethyl as equivalent to 3 -methyl), it is evidently possible to calculate the one unknown quantity, viz., the direction of the moment of quinoline. This has been done, the results being tabulated below as inclinations (counterclockwise denoted by + ) to the $[(4)-\longrightarrow(1)]$ direction :

$$
\begin{array}{cccccc}
2-\mathrm{Me} . & 6-\mathrm{Me} . & 2: 4-\mathrm{Me}_{2} . & 5-\mathrm{NO}_{2} . & 6-\mathrm{NO}_{2} . & 8-\mathrm{NO}_{2} . \\
+35.5^{\circ} & -15 \cdot 5^{\circ} & +17^{\circ} . & \pm 35 \cdot 5^{\circ} & -17 \cdot 5^{\circ} & \pm 49 \cdot 5^{\circ}
\end{array}
$$

Of the two possible signs for the 5 - and the 8 -nitro-derivative, the negative is considered the more correct, by analogy with the 6 -nitro-compound, for which there is no ambiguity.

Discussion.--The real structure of any given quinoline compound might be expected,

(I.)

(Ia.)

(II.)
 in conformity with recent theory (Ingold, Chem. Revs., 1934, 15, No. 2), to lie between two extreme forms corresponding in structures to the types (I) or ( $\mathrm{I} a$ ) and (II). These would constitute the unreal unperturbed forms from which could arise the real and most stable form by
valency exchange degeneracy.
With the aid of the angles now deduced we can assign, qualitatively, the compounds marked with an asterisk in Table I to their places between the extreme types because, in the above two formula types, the $-\mathrm{C}: \mathrm{N}-$ and $-\mathrm{C}-\mathrm{N}$ : links should have sensibly different moments towards the nitrogen atom, the first having the greater; and accordingly, in those compounds where the quinoline component moment has an apparent clockwise inclination to the vertical direction (cf. negative signs to above angles), we infer that a quinoline skeleton of type (I) or (Ia) exists predominantly. A complete decision cannot be made with certainty, but the marked resemblances between quinoline and naphthalene (orientation
phenomena, parallelism of the dipole moments of quinoline and isoquinoline with $\alpha$ - and $\beta$ naphthalene derivatives; cf. Le Fèvre and Smith, loc. cit.; Parts, Z. physikal. Chem., 1930, 10, $B, 264$ ) definitely favour (I). Naphthalene is commonly assumed to have the two quaternary carbon atoms united by a double bond, a formulation supported by dipolemoment measurements, for this hydrocarbon has a zero moment and must therefore, in the isolated state, contain a symmetrical arrangement of bonds [cf. (I)]: a structure of type ( $\mathrm{I} a$ ) would imply a moment of the order of that found for phenanthrene. The present conclusion in the case of quinoline agrees, as far as the heterocyclic ring is concerned, with that reached by Mills and Smith (J., 1922, 121, 2724) from chemical considerations.

Mesomerism.-Alternatively, the inconstancy of our inclination angle values may be a measure of the departure from true vector additivity of dipole moments occurring in this group of compounds by the operation of " mesomeric " effects (Ingold, J., 1933, 1120) ; e.g., with 5 -substituted quinolines little abnormality is to be expected, in contrast to the 6 - or 8 -analogues, which constitutionally resemble $p$ - and o-nitroanilines respectively, and so should similarly display permanent polarisation increments produced by the mechanism of the tautomeric effect. These have been fully discussed by Höjendahl, Sutton, and others (for, references see Ingold, Chem. Revs., loc. cit.) and are of obvious application to the present cases.

2-Methylquinoline and its 4- and 6-Methyl Derivatives.-Quinaldine and 2:4-dimethylquinoline have inclination angles which are in contrast with those derived from the other compounds. In the $\alpha$-methylated quinolines the possibility arises of dynamic isomerism of the type $-\mathrm{N}: \stackrel{\mathrm{C}}{\mathrm{C}}-\mathrm{CH}_{3} \rightleftharpoons-\mathrm{NH}-\mathrm{C}: \mathrm{CH}_{2}$ and their abnormality is probably to be ascribed to this cause. For this reason we prefer not to apply to the apparent angle values the argument used above, which would indicate the existence of a basal structure of type (II), although such a conception is quite in harmony with the zero moment found by Snoek (Physikal. Z., 1934, 35, 196) for 2 : 3-dimethylquinoxaline (III). As an indication of the significance of such tautomerism in the interpretation of the second and fifth measure-
(III.)

ments (Table I), we have examined 2: 6-dimethylquinoline (IV). By symmetry, if (IV) were correct, the Me-C moments should be identical and in antiparallel alinement. The resultant therefore should equal that of quinoline itself, viz., $2 \cdot 19$; experimentally it is found to be $2 \cdot 00$.

Conclusions.-It is concluded that in the quinoline derivatives examined, except the $\alpha$-methyl-containing compounds, the mobilities, typical of benzene and pyridine, of the single and double linkings are so diminished by ring fusion that the skeleton is best formulated as (I), and that the component electric moment, arising from this structure, acts along directions varying from $15^{\circ}$ to $50^{\circ}$ to the axis of the $5: 8$-carbon atoms, to meet it at some point outside the molecule on the side of the 8 -carbon atom.

## Experimental.

Preparation of Materials.-The benzene used was commercial pure material, redistilled and recrystallised, etc., as detailed by Le Fèvre and Smith (J., 1932, 2239).

Quinoline. The commercial " pure " base was fractionated (column), the intermediate onethird, b. p. 238-238. $5^{\circ} / 759 \mathrm{~mm}$., being kept over solid potash for a day and then redistilled.

6-Methylquinoline was prepared from $p$-toluidine by Skraup's method (Monatsh., 1881, 2, 158), a sample of b. p. $258-260^{\circ} / 760 \mathrm{~mm}$. being employed.
$p$-Toluquinaldine, obtained from $p$-toluidine, paraldehyde, and hydrogen chloride (Döbner and Miller, Ber., 1883, 16, 2470), had m. p. $60^{\circ}$, b. p. 265-267 .

2: 4-Dimethylquinoline, prepared from acetylacetone, aniline, and sulphuric acid (Roberts and Turner, J., 1927, 1842), was redistilled; b. p. $264-265^{\circ} / 758 \mathrm{~mm}$.

5-Nitroquinoline. This was prepared directly from quinoline by nitration, since the synthetic product from $m$-nitroaniline is liable to be admixed with the 7 -isomeride. To quinoline ( 50 g .), nitric acid ( $20 \mathrm{c} . \mathrm{c}$., $d \mathbf{1} 5$ ) was added slowly at $0^{\circ}$. The solid cake formed ( 75 g .) was powdered and added in five portions to concentrated sulphuric acid ( 50 c.c., kept at $0^{\circ}$ ), a small quantity of fuming sulphuric acid ( $d 2 \cdot 0,10 \mathrm{c} . c$.) being run in after each addition. Dilution and neutralisation (caustic soda solution) produced an oil, which solidified over-night. This was dissolved in much hot water (with some dilute nitric acid), and the clear filtrate saturated with sodium acetate. After a time the precipitated 5 -nitroquinoline was separated, washed, etc., and finally crystallised from light petroleum; it formed white needles ( 32 g. ), m. p. 72 ${ }^{\circ}$. Complete neutralisation of the nitration solution led to 8 -nitroquinoline ( 9 g. ), which, after crystallisation from dilute alcohol, had m. p. 88-89 ${ }^{\circ}$.

6-Nitroquinoline. This substance was made by the usual Skraup synthesis from arsenic acid (116 g.), concentrated sulphuric acid ( 220 g .), glycerol ( 240 g .) , and p-nitroaniline ( 112 g .) . After $2 \frac{1}{2}-3$ hours' heating, the whole was strongly diluted with water and left over-night. Sodium hydroxide solution was added to the filtrate from this, a mass of impure 6-nitroquinoline being obtained. Separation and dissolution of the mass in hydrochloric acid (norit) afforded, on saturation with ammonia, crystalline 6-nitroquinoline; recrystallisation from dilute alcohol (norit) finally gave the pure substance ( 98 g.), m. p. $148-149^{\circ}$.

8 -Nitroquinoline. This was similarly obtained (arsenic acid, $51.5 \mathrm{~g} . ;$ sulphuric acid, 100 g.; glycerol, $110 \mathrm{~g} . ;$ o-nitroaniline, 50 g .). The highly diluted reaction mass was clarified, and neutralised with sodium hydroxide solution; after 1 hour the brown flocky precipitate was filtered off and crystallised from dilute alcohol (norit) ; m. p. $88-89^{\circ}$ ( 45 g .).

Measurements.-The dielectric constants of dilute solutions of the above compounds in benzene were determined by the resonance method described previously (loc. cit.). These measurements were made at $25^{\circ}$ and in one case at $45^{\circ}$. The refractive indices of the same solutions were determined at $25^{\circ}$ and for the $\mathrm{Na}_{\mathrm{D}}$ line with a Pulfrich refractometer. The

| $P_{1}$ | - | $635 \cdot 74$ | 644.02 | $637 \cdot 51$ | 611.51 |

Whence extrapolated value of $P_{1}$ for $f_{1}=0$ is 713 c.c. at $25^{\circ}$ and 676 c.c. at $45^{\circ}$; $\left[R_{L}\right]_{\mathrm{D}}=47.8$ c.c.; therefore $\mu=0.220(713-47.7)^{\frac{1}{2}}=5 \cdot 67$. Alternatively, we have, by substituting in $P=A+B / T$, $B=175313 \cdot 4$, whence $\mu=5 \cdot 33$. Also, $5 \cdot 67=\left(2 \cdot 19^{2}+4^{2} \pm 2 \times 2.19 \times 4 \times \cos \theta\right)^{\frac{1}{2}}$, from which $\cos \theta=0.6480$, i.e., $\theta=49 \frac{1}{2}^{\circ}$.
densities of the solutions were measured at the same temperatures. From these data the molecular polarisations and refractivities were calculated from the well-known modifications of the Clausius-Mosotti and the Lorenz-Lorentz equation. The significant data are in the foregoing tables, in which the symbols $M, P, R$, refer respectively to the molecular weights, polarisations, and refractions of the components, and $f$ to their mol.-fractions in the solutions, the subscripts 1 and 2 applying to solute and solvent; $\varepsilon, d$, and $n$ are respectively the dielectric constants, densities, and refractive indices of the solutions, and $\mu$ the dipole moments of the solutes.

## The Orientation of Claus and Hoffmann's x-Nitroisoquinoline.

Claus and Hoffmann showed (J. pr. Chem., 1893, 47, 252) that solid isoquinolinium nitrate or sulphate could be nitrated to give in high yield a mononitro-derivative, m. p. $110^{\circ}$, permanganate oxidation of which produced $\alpha$-nitrophthalic acid, showing that either 5 - or 8 -substitution had taken place. No experimental decision on this point was made, although the authors clearly favoured the latter constitution. This ambiguity cannot be resolved by any conclusive theoretical arguments, but the 5 -nitro-structure would be more consistent with analogy. The dipole moments of isoquinoline, of its 1 -chloro-, and of its unoriented nitro-derivative were therefore measured by the same procedure as above.

Preparation of Materials.-The isoquinoline used, after being twice partly frozen and separated from the liquid of lower b. p., had m. p. $24^{\circ}$. We are indebted to Dr. F. M. Hamer for our specimen of 1 -chloroisoquinoline (cf. Fisher and Hamer, J., 1934, 1908). The benzene was that employed previously.

Whence extrapolated value for $f_{1}=0$ is $333 \cdot 0$ c.c. ; $\left[R_{L}\right]_{\mathrm{D}}=47.7$ c.c.; therefore $\mu=0.22(333 \cdot 0-47 \cdot 7)^{\frac{1}{2}}=$ 3.72. Substitution in $\mu_{\text {Resultant }}=\sqrt{\mu_{1}^{2}}+\mu^{2}+2 \mu_{1} \mu_{2} \cos \theta$ gives $3.72^{2}=2.55^{2}+4^{2} \pm 2 \cdot 2 \times 55 \cdot 4$ $\cos \theta$, whence $\cos \theta=-0.4247$, i.e., $\theta=c a .115^{\circ}$.
x -Nitroisoquinoline. This was first obtained as by Claus and Hoffmann (loc. cit.), viz., by addition of the solid nitrate to an excess of well-stirred concentrated sulphuric acid. Later, the following variation was adopted : isoquinoline ( 43 g .) was dissolved in sulphuric acid ( 200 c.c.) directly; considerable heat was evolved, and the solution was cooled to $0^{\circ}$, stirred, and potassium nitrate ( 35 g .) in sulphuric acid ( $200 \mathrm{c} . \mathrm{c}$.) dropped in during 2 hours. After being kept below $50^{\circ}$ for 6 hours, the reaction mixture was poured on ice and neutralised by ammonia. Filtration, etc., afforded the required nitro-derivative in quantitative yield ( 55 g .). The dried substance, crystallised from benzene, had m. p. $110^{\circ}$, as stated by the German authors.

Discussion.-Before discussion of the data, the direction of operation of the moment in the unsubstituted base must be decided. This can be fixed by the consideration of the dipole moment of an isoquinoline derivative of known orientation, and for this purpose 1-chloroisoquinoline was used. The dipole moment of this compound has been estimated at $3 \cdot 33$, a figure which (with $\mu \mathrm{C}-\mathrm{Cl}=1.52^{*}$ ) implies that the isoquinoline vector makes an angle of $71 \frac{1}{2}^{\circ}$ with the $\mathrm{C}-\mathrm{Cl}$ (vertical) direction. Hence the isoquinoline moment has a finite component along the $5: 8$-axis, with the negative end in the direction of the 8 -carbon atom.

The substance in question can now be formulated, for consideration of 8 -nitroisoquinoline shows that the component moments of the nitro-group and the isoquinoline nucleus should make an angle of approximately $71^{\circ}$, whereas with the 5 -nitro-structure the angle subtended by the vectors should be of the order $109^{\circ}$. The found value is $115^{\circ}$. Hence, we suggest that Claus and Hoffmann's compound should be oriented as 5 -nitroisoquinoline.

The authors thank Professor G. M. Bennett for a gift of dimethylquinoline, Professor F. G. Donnan for permission to use apparatus belonging to the Physicochemical Department, and Professor C. K. Ingold for much helpful discussion.
