# 205. The Influence of Solvents and of Other Factors on the Rotation of Optically Active Compounds. Part XXXVII. Asymmetric Solvent Action (continued). 

By T. S. Patterson, Alexander H. Lamberton, and (in part) Robert M. Cunningham.

#### Abstract

From the work herein described it appears that (1) $l$-nicotine and ethyl $d$-tartrate have a considerable mutual solvent influence, (2) the tartrate raises the rotation of the nicotine (in an absolute sense), (3) similarly the nicotine raises the rotation of the tartrate, (4) ethyl $i$-tartrate has a slightly greater effect than ethyl racemate, (5) the isobutyl tartrates show a generally similar and consistent behaviour, as compared with the ethyl derivatives.

Experiments described in Part XXXVI (J., 1937, 1453) dealt with the changes of volume which occur when two unsymmetrical compounds are mixed. In that investigation, the rotational changes observed were only briefly referred to, but those for mixtures of $l$-nicotine with ethyl tartrate and with the isobutyl tartrates are now described more fully. Previous work would lead one to expect that, on mixing ethyl tartrate and nicotine, the rotation of both should be mutually influenced to a considerable extent; and that the change in the rotation of the mixture might be strikingly great in cases where the contributions of the two components were of the same sign, or comparatively small if the contributions of the components happened to be of opposite sign. Although, unfortunately, it is clear, a priori, that no definitive solution to the problem is yet to be expected, the present data are of interest in this connexion.

The ethyl tartrate used was prepared by the hydrogen chloride saturation method and had $\alpha_{56181}^{20}+9 \cdot 45^{\circ}$. The nicotine was purified by means of the zinc chloride double salt, $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{~N}_{2}, 2 \mathrm{HCl}, \mathrm{ZnCl}_{2}, \mathrm{H}_{2} \mathrm{O}$ (Patterson and Fulton, J., 1925, 127, 2493 ; Lowry and Lloyd, J., 1929, 1381). Its rotation and density agreed closely with the data given by Jephcott (J., 1919, 115, 104), Patterson and Fulton (loc. cit.), Lowry and Singh (Compt. rend., 1925, 181, 910), and Lowry and Lloyd (loc. cit.). It was distilled in an atmosphere of nitrogen at $10-15 \mathrm{~mm}$. pressure, atmospheric pressure being finally restored by admission of nitrogen instead of air; and during later work the distillate was shaken vigorously in the nitrogen-filled receiver before removal and use. This was remarkably efficient in preventing oxidation. The nicotine used had $\alpha_{5481}^{20^{\circ}}-206 \cdot 2^{\circ}$. With these samples of ethyl tartrate and nicotine the rotations and densities of three mixtures were determined for three colours of light, at a number of temperatures between $0^{\circ}$ and $100^{\circ}$.

The discussion of the experimental data presents difficulty, inasmuch as it is necessary first to adopt some criterion of what may be considered analogous conditions under which comparisons may be made. We shall not discuss other possibilities, but describe only that one adopted in the sequel, and recorded in the Table. The various solutions were made up to certain definite percentages by weight ; e.g., solution I contained $7.88 \%$ of nicotine and $92 \cdot 12 \%$ of ethyl tartrate. The specific rotation of such a solution, containing two active substances, can have no useful meaning here, so that for comparison of the rotations of the constituents with the rotation of the mixed solution, it is necessary to use observed rotations.* If 10 g . of the above solution be supposed divided into its two constituent parts, the 0.788 g . of nicotine at $0^{\circ}$ would occupy $0.7716 \mathrm{c} . \mathrm{c}$. and the 9.212 g . of ethyl tartrate would occupy 7.5169 c.c.; the sum of these volumes is 8.2885 c.c. If these two quantities were placed one behind the other, so that they could not mix, in a tube of $1 \mathrm{~cm} .{ }^{2}$ cross-section, $\dagger$ the observed rotation, for light of $\lambda=5461$, due to the nicotine (which would occupy a length of 7.716 mm . of the tube) would be $-15.98^{\circ}$, i.e., $0.07716 \times-207^{\circ}$ (length of column, in dcm., $\times$ observed rotation of nicotine at $0^{\circ}$ ), and that due to the ethyl tartrate would similarly be $+4 \cdot 135^{\circ}$, i.e., $0.75169 \times 5 \cdot 5^{\circ}$. The sum

of the separate rotations would therefore be $-11.85^{\circ}$. If the two solutions were now mixed, the volume would become 8.247 c.c., so that there is a slight contraction, which, meantime at least, may be neglected. The change in rotation, however, is considerable; the rotation of the mixed solution $\left(-4.84^{\circ}\right)$ is higher than the sum of the two separate rotations ( $-11.85^{\circ}$ ) by $7 \cdot 01^{\circ}$.

Data calculated in this way for three such solutions are given in the Table for $0^{\circ}$ and $99^{\circ}, *$ and it will be seen from the last column that there is in all cases a considerable difference between the observed and the calculated values. The differences are greater at $0^{\circ}$ than at $99^{\circ}$. We think it probable that with further increase of temperature these differences would fall to zero and then increase again.

In the Table are also shown the results for three similar solutions of nicotine with ethyl racemate. In solution IV at $0^{\circ}$ the rotation of 0.788 g . ( $=0.771 \mathrm{c.c}$.) of nicotine would be, as before, $-15.98^{\circ}$, and, the rotation of the ethyl racemate being presumably zero, the total rotation for a length of 82.903 mm . should be $-15.98^{\circ}$. The actual rotation for 100 mm . was found to be $-15.92^{\circ}$ and therefore for $82.903 \mathrm{~mm} .,-13 \cdot 20^{\circ}$, i.e., $2.78^{\circ}$ higher than would be expected if the phenomenon were purely additive. Similar differences were found for the other solutions and temperatures.

If it be assumed for the moment that $l$-nicotine exerts the same influence upon the rotation of ethyl $d$-tartrate as it does upon that of ethyl $l$-tartrate, so that the rotation of $l$-nicotine dissolved in either of them is, from experiment (IV), $-13 \cdot 20^{\circ}$, then the rotation

[^2]of the $d$-ester in a solution of this concentration must be $+8 \cdot 36^{\circ}$, i.e., $-4 \cdot 84^{\circ}$, the rotation of I, minus that of IV. Hence nicotine appears to raise the rotation of ethyl $d$-tartrate from $+4 \cdot 13^{\circ}$ in the homogeneous condition, for the quantity now under consideration ( $l=75 \cdot 17 \mathrm{~mm}$.), to $+8 \cdot 36^{\circ}$, under the conditions of solution IV at $0^{\circ}$.

On the other hand since the observed rotation of the undiluted $l$-nicotine in IV at $0^{\circ}$ is $-15.98^{\circ}$ and in the mixed solution IV it is $-13 \cdot 2^{\circ}$, ethyl racemate raises considerably (makes less negative) the rotation of $l$-nicotine. Thus the rotation of ethyl $d$-tartrate would presumably become more positive, and that of ethyl $l$-tartrate more negative, by solution in $d l$-nicotine, whereas the rotation of $l$-nicotine becomes less negative and that of $d$-nicotine would become less positive by solution in ethyl $d l$-tartrate.

Since ethyl $i$-tartrate is a solid of m. p. $57^{\circ}$, it was only possible to examine this ester in a solution of composition corresponding to solutions III and VI, and only to compare these at $99^{\circ}$. As is shown in the Table, solution VII, $l$-nicotine ( 6.0197 g .) in ethyl $i$-tartrate ( 3.9803 g.) at $99^{\circ}$, changes its observed rotation from $-124 \cdot 75^{\circ}$ to $-119 \cdot 7^{\circ}$, which is $1^{\circ}$ more than the change produced by ethyl dl -tartrate $\left(-120 \cdot 7^{\circ}\right)$. The influence is in the same direction.

We also examined similar solutions of nicotine in isobutyl $d$-, $l$ -,$d l$-, and $i$-tartrate, and again, since these esters are solids at room temperature, comparison of rotation values can only be made, directly, at higher temperatures. The data obtained are also shown in the Table.

Dealing with solutions VIII, IX, and X in the same way as with I-VI, but making the actual comparisons at $99^{\circ}$, we find that: (1) in all cases there is a distinct and, since it is mostly suffered by the much less active constituent of the solutions, considerable change of rotation when the two active substances are mixed; (2) from the data for X , it appears that the change of rotation of nicotine owing to admixture with isobutyl racemate is comparatively slight, $1 \cdot 8^{\circ}$, but, as with ethyl racemate (VI), it is again in an upward direction; (3) from the value for VIII ( $-109 \cdot 2^{\circ}$ ) minus that for $\mathrm{X}\left(-123^{\circ}\right)$, the value $+13.8^{\circ}$ is found as the apparent observed rotation at this concentration, for isobutyl $d$-tartrate in $l$-nicotine (for 103.093 mm . length of column); and similarly from IX and X the value $-14^{\circ}$ for the apparent observed rotation of $i$ sobutyl $l$-tartrate in $l$-nicotine is found, numbers which agree as closely with each other as could be expected. Thus $l$-nicotine raises the rotation of isobutyl $d$-tartrate and depresses (makes more negative) that of the $l$-ester; whereas isobutyl tartrate (presumably both $d$ - and $l$-) raises slightly (makes less negative) the rotation of $l$-nicotine.

In all cases temperature-rotation curves for these solutions have been plotted and analysed, but the only point in regard to them that need be mentioned here is that a minimum rotation, which appears distinctly in the isobutyl $d l$-tartrate solution (X) at a temperature of about $25^{\circ}$, is not quite reached in the corresponding $i$-tartrate (XI) at zero, but clearly would appear on further cooling.

Similar results to those given above-but using specific rotation and the temperature $0^{\circ}$-are obtained by the method adopted in Part XXXVI (loc. cit.). If from the present data for VIII the specific rotation at $0^{\circ}$ be calculated as if the whole rotation were due to the isobutyl $d$-tartrate ( $p=39 \cdot 8$ ), we find the composite value $x-y=$ $-104.85 /(0.398 \times 1.0653)=-247.3^{\circ}$, where $x$ may be supposed to be the part of this specific rotation, due to the $d$-tartrate, and from IX for the $l$-tartrate $-x-y=$ $-141.45 /(0.395 \times 1.0658)=-333.5^{\circ}$. Then, by elimination, $x= \pm 43 \cdot 1^{\circ}$.

Similarly, from the data for the same two solutions but calculated with reference to the nicotine ( $p=60 \cdot 2$ ), or by eliminating $y$ in the above equations and multiplying the result by $39 \cdot 8 / 60 \cdot 2$, we find the specific rotation of the nicotine in these solutions to be $-192 \cdot 0^{\circ}$.

By extrapolation, the specific rotation of homogeneous isobutyl $d$-tartrate at $0^{\circ}$ should be about $+15.3^{\circ}(\mathrm{J} ., 1913,103,174 ; 1916,109,1147,1162)$, so that $l$-nicotine appears to raise considerably the specific rotation of isobutyl $d$-tartrate, whilst, since the specific rotation of homogeneous $l$-nicotine at $0^{\circ}$ is $-198^{\circ}$ (solution X), isobutyl $d l$-tartrate appears to raise slightly the rotation of $l$-nicotine.

Comparing VI and X at $99^{\circ}$, we find that ethyl racemate raises the rotation of $l$-nicotine more than does isobutyl racemate ( $4 \cdot 1^{\circ}$ as against $1 \cdot 8^{\circ}$ ); and, from VII and XI, that ethyl
$i$-tartrate raises the rotation of $l$-nicotine more than does $i$ sobutyl $i$-tartrate $\left(5 \cdot 1^{\circ}\right.$ as compared with $2 \cdot 4^{\circ}$ ).

* By extrapolation.

Ethyl $i$-tartrate was prepared by Frankland and Aston's continuous method (J., 1901, 79, 517) from dehydrated mesotartaric acid, m. p. $143^{\circ}$. The ester, crystallised from carbon disulphide and subsequently distilled, melted at $57^{\circ}$ with slight preliminary softening from $54^{\circ}$. Kühn and Wagner-Jauregg give m. p. $55^{\circ}$ (Ber., 1928, 61, 503).

The isobutyl $d-, l$-, and $d l$-esters were prepared by the Fischer-Speier method, purified by crystallisation from benzene, and, finally, distillation at $5-8 \mathrm{~mm}$. pressure (Patterson and

Lamberton, J., 1937, 1458). isoButyl i-tartrate, prepared and purified in the same manner, had m. p. $81-82^{\circ}$, b. p. $176-178^{\circ} / 12 \mathrm{~mm}$. (Found : C, $55 \cdot 3 ; \mathrm{H}, 8.5$. $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{6}$ requires C, $54.9 ; \mathrm{H}, 8.5 \%$ ) ; solubility, 17 g . of ester in 100 g . of benzene at $20^{\circ}$.

Densities determined (of molten ethyl and isobutyl $i$-tartrates). Ethyl $i$-tartrate : $d_{4^{\circ}}^{60 \cdot 7^{\circ}}$ $1 \cdot 1783, d_{4^{\circ}}^{70 \cdot 4^{\circ}} 1 \cdot 1674, d_{4^{\circ}}^{80 \cdot 5^{\circ}} 1 \cdot 1586, d_{4^{\circ}}^{81 \cdot 8^{\circ}} 1 \cdot 1568, d_{4^{\circ}}^{88 \cdot 5^{\circ}} 1 \cdot 1499, d_{4^{\circ}}^{93 \cdot 9^{\circ}} 1 \cdot 1441$; whence $d_{4^{\circ}}^{100^{\circ}}=1 \cdot 1384$. isoButyl $i$-tartrate: $d_{4^{\circ}}^{83 \cdot 4^{\circ}} 1 \cdot 0356, ~ d_{4^{\circ}}^{85 \cdot 0^{\circ}} 1 \cdot 0348, ~ d_{4^{\circ}}^{87 \cdot 7^{\circ}} 1 \cdot 0327, d_{4^{\circ}}^{91 \cdot 6^{\circ}} 1 \cdot 0296, \quad d_{4^{\circ}}^{94 \cdot 5^{\circ}} 1 \cdot 0258, ~ d_{4^{\circ}}^{95 \cdot 2^{\circ}}$ $1.0261, d_{4^{97}}{ }^{\circ} 1.0236$; whence $d_{4^{\circ}}^{100^{\circ}}=1.0216$.

## Ethyl mesotartrate and nicotine.

Solution VII. Ethyl mesotartrate, $p=39.803$; nicotine, $q=60 \cdot 197$.

The authors' thanks are offered to the Carnegie Trustees for the Universities of Scotland for grants covering part of the expense of this work, to whom also one of them (A. H. L.) is indebted for a Carnegie Research Scholarship.

[^3]
[^0]:    * In the Experimental Data, when both constituents of a solution are active, observed rotations only are recorded. If only one constituent is active, the specific rotation is mostly recorded, as this value is often useful and, from it, the observed rotation can easily be calculated.
    $\dagger$ In order to reduce the data to the usual standards of comparison.

[^1]:    * From Patterson and Fulton (J. 1925, 127, 2444).

[^2]:    * This temperature was chosen as it happened to be that for which the rotation of nicotine was directly observed (Patterson and Fulton, J., 1925, 12\%, 2444). The other data are taken mostly from graphs by extrapolation.
