## 199. The Stereochemistry of Sesquiethylenediaminetrimethylplatinic Iodide.

By Mary R. Truter and (in part) E. G. Cox.

Sesquiethylenediaminetrimethylplatinic iodide has been shown by $X$-ray crystal-structure analysis to contain the cation $\left[\mathrm{en}\left(\mathrm{CH}_{3}\right)_{3} \mathrm{Pt} \text { en } \mathrm{Pt}\left(\mathrm{CH}_{3}\right)_{3} \mathrm{en}\right]^{2+}$. The two halves of the ion are related by a 2 -fold axis perpendicular to the $\mathrm{C}-\mathrm{C}$ bond of the bridging ethylenediamine molecule. Each platinum atom is surrounded octahedrally by three nitrogen and three carbon atoms in the cis-configuration of the type $\mathrm{PtA}_{3} \mathrm{X}_{3}$.

SesQuiethylenediaminetrimethylplatinic iodide, empirical formula $\mathrm{Pt}\left(\mathrm{CH}_{3}\right)_{3} \mathrm{I}, 1 \frac{1}{2}$ en (en = ethylenediamine), was first prepared by Lile and Menzies. ${ }^{1}$ The molecule must clearly contain at least two platinum atoms, and, as Lile and Menzies suggested, ${ }^{2}$ its most likely formation is as a complex salt ( I ), in the positive ion of which the platinum atoms would be held together by one or more ethylenediamine groups and each have an octahedral
(I) $\left[\mathrm{Pt}_{2} \mathrm{Me}_{6} \mathrm{en}_{3}\right] \mathrm{I}_{4} \quad\left[\mathrm{PtMe}_{6}\right][\mathrm{Pt} \mathrm{en} 3] \mathrm{I}_{2}$ (II)
configuration. The formation of polynuclear structures by means of halogen or methyl bridges such as occur in trimethylplatinic chloride and tetramethylplatinum ${ }^{3}$ is extremely

(III)

(IV)

(V)

(VI)
unlikely, but the structure (II), cannot be entirely be excluded. The $X$-ray investigation reported in this paper was undertaken to discriminate between this structure (II) and the various stereochemical forms of structure (I).

${ }^{2}$ Cf. Foss and Gibson, J., 1951, 299.
${ }^{3}$ Rundle and Sturdivant, J. Amer. Chem. Soc., 1947, 69, 1561.

Not counting enantiomers there.are eight possible isomers of structure (I)—one with three en bridges, two with two bridges, and five with one bridge; of these, however, only (III), (IV), (V), and (VI), together with (II), satisfy the requirement which emerged from the preliminary $X$-ray examination, that the molecule must have at least a two-fold axis of symmetry. While further discrimination could be effected by finding the positions of the platinum atoms, a detailed analysis has been necessary to determine the structure finally; notwithstanding the large scattering power of platinum and iodine it has been possible to locate all the carbon and nitrogen atoms unequivocally and thereby to show that the structure is (VI).

## Experimental

The sample was prepared and analysed by Messrs. Johnson Matthey and Co. [Found : Pt, 42.6. Calc. for $\mathrm{Pt}_{2} \mathrm{en}_{3}\left(\mathrm{CH}_{3}\right)_{6} \mathrm{I}_{2}, \mathrm{Pt}, 42.7 \%$ ]. The acicular crystals were set up about the needle axis [001], and rotation and Weissenberg photographs were taken with $\mathrm{Cu}-K_{\alpha}$ radiation. The unit cell dimensions are $a=16.54 \pm 0.01, b=12.10 \pm 0.01, c=12.92 \pm 0.05 \AA$; the value for $c$ was obtained by measurement of a rotation photograph, and the other two by Straumanis's method (approximate values having been obtained from Weissenberg photographs). The measured volume, $2586 \AA^{3}$, with 4 molecules ( $M, 914$ ) per unit cell gives a calculated density of $2 \cdot 38$. It was not possible to measure the density of the iodide because the small crystals dissolved in both aqueous and organic liquids; however the density of the nitrate, $\mathrm{Pt}_{2} \mathrm{en}_{3} \mathrm{Me}_{6}\left(\mathrm{NO}_{3}\right)_{2}$, determined by flotation in cadmium borotungstate solution, was 2.12, so that 2.38 is a reasonable value for the iodide.

The following classes of reflections were found to be systematically absent: $h k l$ when $h+k+l=2 n+1 ; 0 k l$ when $k=2 n+1(l=2 n+1) ; h 0 l$ when $h=2 n+1(l=2 n+1)$. Hence the space group is either (i) Iba - C $C_{2 \downarrow}^{21}$ or (ii) Ibam - $D_{2 k}^{28}$, the molecular symmetry required being (i) 2 or (ii) 222 or $2 / \mathrm{m}$.

Weissenberg photographs of the ( $h k 0$ ) zone were taken by a multiple-film technique. Of a possible 128 reflections, 100 were observed and their intensities estimated visually by comparison with a calibration slip; Lorentz and polarisation corrections were applied, giving a set of relative values of $\mathrm{F}^{2}$. Approximately absolute values and temperature factors were determined by Wilson's method. The intensities were redetermined by a different observer and the agreement $\sum|\Delta F| / \sum \mathrm{F}$ between the two sets was 0.073 .

No absorption correction was made. The crystal approximated to a cylinder 0.01 mm . in diameter and 1.0 mm . long; the linear absorption coefficient is $425 \mathrm{~cm} .^{-1}$.

## Structure determination.

In either possible space group the molecules (or constituent ions) of sesquiethylenediaminetrimethylplatinic iodide must occupy special positions, in Ibam with symmetry 222 (three two-fold axes) or $2 / m$ (two-fold axis and plane) and in Iba with symmetry 2 (two-fold axis). In form (IV) the two-fold symmetry axis must pass through both platinum atoms, whereas in (III), (V), and (VI) it must be perpendicular to the line joining them; form (IV) can therefore be rejected because it is impossible to accommodate two molecules end-to-end along the Pt - Pt direction in a $c$-axis of only $13 \AA$, as would be required by the symmetry. The possible symmetries, positions of the platinum atoms, and corresponding Patterson peaks in an $h k 0$ projection for the other stereochemical forms are as follows :

|  | Symmetry |  | Pt co-ordinates |  | Patterson Pt peaks |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Form. | Ibam | Iba | Ibam | Iba | in projection |
| (II) | 222 | 2 | $0,0, \frac{1}{4}$, etc. | $00 z$, etc. | $0, \frac{1}{2} ; \frac{1}{2}, 0$ |
| (III) | - | 2 | and $\frac{1}{2}, 0, \frac{1}{4}$, etc. | and $0, \frac{1}{2}, z^{\prime}$, etc. | $2 x, 2 y ; 2 x, 0 ; 0,2 y$ |
| (V) | $2 \mid m$ | 2 | $x, y, 0$, etc. | $x y z$, etc. | $2 x, 2 y ; 2 x, 0 ; 0,2 y$ |
| (VI) | - | 2 |  | $x y z$, etc. | $2 x, 2 y ; 2 x, 0 ; 0,2 y$ |

The Table shows that the location of the platinum peaks in an ( $h k 0$ ) Patterson projection will discriminate between form (II) on the one hand and (III), (V), and (VI) on the other, but that further information will be necessary to distinguish between the last three.

Fig. 1. Electron density projection along [001], the contours are at $10 \varepsilon / \AA^{2}$ intervals, the zero contour is dotted.

Fig. 2. Electron density difference ( $\rho_{0}-\rho_{c}$ ) projected along [001], contours at $4 \varepsilon / \AA^{2}$, negative contours dashed, zero dotted.

Fig. 3. Electron density difference $\left(\rho_{0}-\rho_{c}\right)$ projected along [001] calculated from reflections with $\sin \theta<0.5$. Positive contours full lines, zero dotted lines, negative contours dashed lines, at arbitrary equal intervals.

An ( $h k 0$ ) Patterson projection was computed and gave a consistent set of $\mathrm{Pt}-\mathrm{Pt}$ peaks at $0,2 y, 2 x, 0$, and $2 x, 2 y$, with $x=0 \cdot 110, y=0 \cdot 215$, and Pt-I and I-I peaks corresponding to iodine atoms at $x=0.18$ and $y=0.50$. There are no peaks at $0, \frac{1}{2}$, so that the structure (II) can be eliminated. Discrimination between the other possibilities would be effected only by finding the carbon and nitrogen atoms and since it was hardly to be expected that these could be located from a Patterson synthesis, it was now necessary to compute Fourier syntheses, in the first instance on the assumption that the signs of all the terms were determined by the contributions of the platinum and the iodine atoms. Some structure factors were calculated from the co-ordinates given above, with the scattering factors for platinum and iodine from the International Tables multiplied by a temperature factor $\exp -B\left(\sin ^{2} \theta\right) / \lambda^{2}$ with $B=2.0 \times 10^{-16} \mathrm{~cm} .^{2}$; this value of $B$ was obtained by Wilson's method. ${ }^{4}$ Reasonable agreement with the observed structure factors was obtained, so the signs of all F's were calculated from the Patterson co-ordinates and used with the observed amplitudes to carry out a Fourier synthesis. The resulting projection of the electron density is shown in Fig. 1; the positions of the maxima are Pt at $0 \cdot 112,0.218$, and I at $0 \cdot 184,0.500$, the latter peak being due to the overlapping of two iodide ions at $x, y, z$ and $x, y, \frac{1}{2}+z$, with $y$ nearly $\frac{1}{2}$. The low density in the regions near 0,0 and $0, \frac{1}{2}$ indicates that a triple ethylenediamine bridge is unlikely while the high density at about $\frac{1}{4}, \frac{1}{4}$ is consistent with a non-bridging chelate ethylenediamine so that although individual light atoms are not yet clearly shown this preliminary glimpse suggests configuration (V) or (VI).

In the hope of resolving the light atoms a difference synthesis (in which the coefficients were observed structure amplitudes minus amplitudes calculated for platinum and iodine only) was calculated, the signs being determined by the Pt and I co-ordinates from the Fourier map except that $y_{\mathrm{I}}$ was arbitrarily taken to be $0 \cdot 490$. The most important feature in the resulting ( $\rho_{0}-\rho_{c}$ ) map (Fig. 2) is the negative region ( $\rho_{0}<\rho_{c}$ ) round the iodine position; there is no trace of the positive peak to be expected if further removal from $y=\frac{1}{2}$ is required, and the explanation must be that the temperature factor of the iodine is too low; examination of Fig. 1 also shows an electron density for the superimposed iodide ions lower than that to be expected from a comparison with the platinum peak. Accordingly, for the subsequent calculations, the $B$ factor for iodine was assumed to be 3.0 ; values of $B=2.0$ and $B=3.0$ for platinum and iodine respectively correspond to r.m.s. displacements of 0.16 and $0 \cdot 195 \AA$, which are almost exactly in the ratio, $0 \cdot 81$, to be expected from the atomic masses.

Fig. 2, although still not showing the light atoms very clearly, indicates the need for small shifts of the platinum and iodine atoms, and the co-ordinates finally adopted were: Pt, $x=0 \cdot 111, y=0.216 ;$ I, $x=0 \cdot 181, y=0.495$; the last co-ordinate was chosen after calculations by trial and error with the ( $0 k 0$ ) planes. The agreement index $R=$ $\sum\left|\mathrm{F}_{0}-\mathrm{F}_{\mathrm{c}}\right| / \Sigma\left|\mathrm{F}_{0}\right|$ at this stage was 0.20 .

Although the value of $R$ calculated for all planes was $0 \cdot 20$, that for planes with sin $\theta<0.5$ was 0.25 and that for planes with $\sin 0>0.5$ was 0.16 , in complete contrast to the normal increase of $R$ with $\sin \theta$. This was clearly due to the fact that the light atoms, not yet allowed for in the calculated F's, make a much larger contribution to the low-order than to high-order planes. Accordingly, an ( $h k 0$ ) difference synthesis was calculated with F's for planes having $\sin \theta<0.5$ only, with the result (Fig. 3) that light atom peaks appeared clearly.

The large peaks $A, B$, and $C$ evidently each represent more than one atom and it was assumed that $A$ and $B$ were due to non-bridging ethylenediamine molecules viewed edge-on in the projection as shown. In addition, after preliminary trials of other possibilities which gave less good agreement, $C$ was taken to be two methyl groups attached to the same platinum atom, and overlapping in projection. If the platinum valencies were octahedral there should be atoms at approximately $D$ and $E$, and of these evidently $D$ is the nitrogen of the bridging ethylenediamine and $F$ is the $\mathrm{CH}_{2}$ of this bridge (the 2 -fold axis of the molecule is thus at $0, \frac{1}{2}, z$. With these assumptions and some adjustments of the atomic positions in detail the agreement index was reduced to $R=0.118$ for ( $h k 0$ ) planes with

$\sin \theta<0.5$ and $R=0.143$ for all ( $h k 0$ ) planes. A table of observed and calculated structure) factors is given.) This very substantial improvement in $R$ leaves no doubt as to the correctness of the assigned structure which is (VI), i.e., one in which each platinum atom has cis-configuration of the attached $\mathrm{C}_{3} \mathrm{~N}_{3}$. The final fractional co-ordinates are :

|  |  |  |  | $2 N$ <br> (peak A) | 2 C <br> (peak B) | 2 Me <br> (peak C) | Me <br> (peak E) | N <br> (bridge) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{x}$ | $\ldots \ldots .$. | 0.111 | 0.181 | 0.213 | 0.298 | 0.000 | 0.135 | 0.088 |
| $\boldsymbol{y}$ | $\ldots . . .$. | 0.216 | 0.495 | 0.231 | 0.252 | 0.184 | 0.015 | 0.408 |

Owing to overlap in the projection the $\mathrm{Pt}-\mathrm{C}$ and $\mathrm{Pt}-\mathrm{N}$ distances cannot be considered to be very accurate, but their average value is $2 \cdot 45 \AA$ which is in agreement with accepted values. The $\mathrm{Pt}-\mathrm{Pt}$ distance is $7 \cdot 79 \AA$.

We are indebted to Dr. R. C. Menzies for drawing our attention to this problem, and for arranging for a supply of the material, which was very kindly lent to us by Messrs. Johnson Matthey \& Co. We thank Mrs. R. G. Barclay who took the photographs and determined one set of intensities. We gratefully acknowledge financial assistance from the Royal Society and Imperial Chemical Industries Limited.
